The Ministry of Health, Labour and Welfare Ministerial Notification No. 65

Pursuant to Paragraph 1, Article 41 of the Pharmaceutical Affairs Law (Law No. 145, 1960), the Japanese Pharmacopoeia (hereinafter referred to as “new Pharmacopoeia”), which has been established as follows*, shall be applied on April 1, 2011. However, in the case of drugs which are listed in the Pharmacopoeia (hereinafter referred to as “previous Pharmacopoeia”) [limited to those listed in the Japanese Pharmacopoeia whose standards are changed in accordance with this notification (hereinafter referred to as “new Pharmacopoeia’’)] and drugs which have been approved as of April 1, 2011 as prescribed under Paragraph 1, Article 14 of the same law [including drugs the Minister of Health, Labour and Welfare specifies (the Ministry of Health and Welfare Ministerial Notification No. 104, 1994) as those exempted from marketing approval pursuant to Paragraph 1, Article 14 of the Pharmaceutical Affairs Law (hereinafter referred to as “drugs exempted from approval’’)], the Name and Standards established in the previous Pharmacopoeia (limited to part of the Name and Standards for the drugs concerned) may be accepted to conform to the Name and Standards established in the new Pharmacopoeia before and on September 30, 2012. In the case of drugs which are listed in the new Pharmacopoeia (excluding those listed in the previous Pharmacopoeia) and drugs which have been approved as of April 1, 2011 as prescribed under Paragraph 1, Article 14 of the same law (including those exempted from approval), they may be accepted as those being not listed in the new Pharmacopoeia before and on September 30, 2012.

Ritsuo Hosokawa
The Minister of Health, Labour and Welfare

March 24, 2011

(The text referred to by the term “as follows” are omitted here. All of them are made available for public exhibition at the Evaluation and Licensing Division, Pharmaceutical and Food Safety Bureau, Ministry of Health, Labour and Welfare, at each Regional Bureau of Health and Welfare, and at each Prefectural Office in Japan).

*The term “as follows” here indicates the contents of the Japanese Pharmacopoeia Sixteenth Edition from General Notices to Ultraviolet-visible Reference Spectra (pp. 1 - 2131).

General Rules for Crude Drugs ........................................................................ 5

General Rules for Preparations ......................................................................... 7

General Tests, Processes and Apparatus ..........................................................25

1. Chemical Methods
   1.01 Alcohol Number Determination ............................................................25
   1.02 Ammonium Limit Test ...........................................................................27
   1.03 Chloride Limit Test ..............................................................................28
   1.04 Flame Coloration Test ..........................................................................28
   1.05 Mineral Oil Test ..................................................................................28
   1.06 Oxygen Flask Combustion Method ......................................................28
   1.07 Heavy Metals Limit Test ......................................................................29
   1.08 Nitrogen Determination (Semimicro-Kjeldahl Method) .......................30
   1.09 Qualitative Tests ................................................................................31
   1.10 Iron Limit Test ....................................................................................37
   1.11 Arsenic Limit Test ...............................................................................37
   1.12 Methanol Test ......................................................................................39
   1.13 Fats and Fatty Oils Test ......................................................................39
   1.14 Sulfate Limit Test ...............................................................................41
   1.15 Readily Carbonizable Substances Test .................................................41

2. Physical Methods
   Chromatography
      2.01 Liquid Chromatography .....................................................................42
      2.02 Gas Chromatography ........................................................................45
      2.03 Thin-layer Chromatography ..............................................................47
      2.04 Amino Acid Analysis of Proteins ......................................................47
   Spectroscopic Methods
      2.21 Nuclear Magnetic Resonance Spectroscopy .......................................48
      2.22 Fluorometry ......................................................................................50
      2.23 Atomic Absorption Spectrophotometry ............................................51
      2.24 Ultraviolet-visible Spectrophotometry ..............................................52
      2.25 Infrared Spectrophotometry ...............................................................53
   Other Physical Methods
      2.41 Loss on Drying Test ..........................................................................55
      2.42 Congealing Point Determination ......................................................55
      2.43 Loss on Ignition Test ..........................................................................56
      2.44 Residue on Ignition Test ....................................................................56
      2.45 Refractive Index Determination ..........................................................56
      2.46 Residual Solvents Test ........................................................................57
      2.47 Osmolality Determination ...................................................................57
      2.48 Water Determination (Karl Fischer Method) .....................................58
   2.49 Optical Rotation Determination ............................................................61
      2.50 Endpoint Detection Methods in Titrimetry .........................................62
      2.51 Conductivity Measurement ................................................................63
      2.52 Thermal Analysis ...............................................................................65
      2.53 Viscosity Determination ...................................................................67
      2.54 pH Determination ............................................................................69
      2.55 Vitamin A Assay ...............................................................................71
      2.56 Determination of Specific Gravity and Density ..................................72
      2.57 Boiling Point and Distilling Range Test ..............................................74
      2.58 X-Ray Powder Diffraction Method ....................................................75
      2.59 Test for Total Organic Carbon .........................................................79
      2.60 Melting Point Determination .............................................................80
   3. Powder Property Determinations
      3.01 Determination of Bulk and Tapped Densities .....................................82
      3.02 Specific Surface Area by Gas Adsorption .........................................84
      3.03 Powder Particle Density Determination ...........................................86
      3.04 Particle Size Determination ...............................................................87
   4. Biological Tests/Biochemical Tests/Microbial Tests
      4.01 Bacterial Endotoxins Test ................................................................92
      4.02 Microbial Assay for Antibiotics .......................................................96
      4.03 Digestion Test ..................................................................................100
      4.04 Pyrogen Test ....................................................................................103
      4.05 Microbial Limit Test .........................................................................103
      4.06 Sterility Test .....................................................................................114
   5. Tests for Crude Drugs
      5.01 Crude Drugs Test ...............................................................................117
      5.02 Microbial Limit Test for Crude Drugs ..............................................120
   6. Tests for Preparations
      6.01 Test for Metal Particles in Ophthalmic Ointments ...............................126
      6.02 Uniformity of Dosage Units .............................................................127
      6.03 Particle Size Distribution Test for Preparations ................................129
      6.04 Test for Acid-neutralizing Capacity of Gastrointestinal Medicines ...129
      6.05 Test for Extractable Volume of Parenteral Preparations .................130
      6.06 Foreign Insoluble Matter Test for Injections .................................131
      6.07 Insoluble Particulate Matter Test for Injections ..............................131
      6.08 Insoluble Particulate Matter Test for Ophthalmic Solutions ............134
      6.09 Disintegration Test ...........................................................................135
      6.10 Dissolution Test ...............................................................................137
6.11 Foreign Insoluble Matter Test for Ophthalmic Solutions ..................................141

7. Tests for Containers and Packing Materials
7.01 Test for Glass Containers for Injections .........................................................141
7.02 Test Methods for Plastic Containers .................................................................142
7.03 Test for Rubber Closure for Aqueous Infusions .............................................148

8. Other Methods
8.01 Sterilization and Aseptic Manipulation ...............................................................149

9. Reference Standards; Standard Solutions; Reagents, Test Solutions; Measuring Instruments, Appliances, etc.
9.01 Reference Standards ..............................................................................................150
9.21 Standard Solutions for Volumetric Analysis .....................................................153
9.22 Standard Solutions ...............................................................................................164
9.23 Matching Fluids for Color ....................................................................................166
9.41 Reagents, Test Solutions .......................................................................................167
9.42 Solid Supports/Column Packings for Chromatography ......................................306
9.43 Filter Papers, Filters for filtration, Test Papers, Crucibles, etc. .........................308
9.44 Standard Particles, etc. ...........................................................................................308
9.61 Optical Filters for Wavelength and Transmission Rate Calibration ....................309
9.62 Measuring Instruments, Appliances .....................................................................309
9.63 Thermometers .......................................................................................................310

Official Monographs ..................................................................................................313

Crude Drugs ..................................................................................................................1593

In July 2006, the Committee on JP established the basic principles for the preparation of the JP 16th Edition, setting out the roles and characteristics of the JP, the definite measures for the revision, and the date of the revision.

At the Committee, the five basic principles of JP, which we refer to as the “five pillars”, were established as follows: 1) Including all drugs which are important from the viewpoint of health care and medical treatment; 2) Making qualitative improvement by introducing the latest science and technology; 3) Promoting internationalization; 4) Making prompt partial revision as necessary and facilitating smooth administrative operation; and 5) Ensuring transparency regarding the revision, and disseminating the JP to the public. It was agreed that the Committee on JP should make efforts, on the basis of these principles, to ensure that the JP is used more effectively in the fields of health care and medical treatment by taking appropriate measurements, including getting the understanding and cooperation of other parties concerned.

It was agreed that the JP should provide an official standard, being required to assure the quality of medicines in Japan in response to the progress of science and technology and medical demands at the time. It should define the standards for specifications, as well as the methods of testing to assure overall quality of all drugs in principle, and it should have a role in clarifying the criteria for quality assurance of drugs that are recognized to be essential for public health and medical treatment.

The JP has been prepared with the aid of the knowledge and experience of many professionals in the pharmaceutical field. Therefore, the JP should have the characteristics of an official standard, which might be widely used by all parties concerned. It should provide information and understanding about the quality of drugs to the public, and it should be conducive to smooth and effective regulatory control of the quality of drugs, as well as promoting and maintaining international consistency and harmonization of technical requirements.

It was also agreed that JP articles should cover drugs, which are important from the viewpoint of health care and medical treatment, clinical results and frequency of use, as soon as possible after they reach the market.

The target date for the publication of JP 16th Edition (the Japanese edition) was set as April 2011.

JP Expert Committees are organized with the following panels: Panel on the Principles of Revisions; Sub-committee on the Principles of Revisions; Panel on Medicinal Chemicals; Panel on Antibiotics; Panel on Biologicals; Panel on Crude Drugs; Panel on Pharmaceutical Excipients; Panel on Physico-Chemical Methods; Panel on Preparations; Panel on Physical Methods; Panel on Biological Tests; Panel on Nomenclature; Panel on International Harmonization; Panel on Pharmaceutical Water; and Panel on Reference Standards. Furthermore, working groups are established under the Panel on Physico-Chemical Methods, Panel on Preparations and Panel on Biological Tests to expedite discussion on revision drafts.

In the Committee on JP, Takao Hayakawa took the role of chairman from July 2003 to December 2010, and Mitsuru Hashida from January 2011 to March 2011.

In addition to the regular revision every five years in line with the basic principles for the preparation of the JP it was agreed that partial revision should be done as necessary to take account of recent progress of science and in the interests of international harmonization.

In accordance with the above principles, the panels initiated deliberations on selection of articles, and on revisions for General Notices, General Rules for Crude Drugs, General Rules for Preparations, General Tests, Monographs and so on.

Draft revisions covering subjects in General Notices, General Rules for Crude Drugs, General Rules for Preparations, General Tests and Monographs, for which discussions were finished between September 2005 and March 2007, were prepared for a supplement to the JP 15. They were examined by the Committee on JP in April 2007, followed by the Pharmaceutical Affairs and Food Sanitation Council (PAFSC) in June 2007, and then submitted to the Minister of Health, Labour and Welfare. The supplement was named “Supplement I to the JP 15th Edition”, promulgated on September 28, 2007 by Ministerial Notification No. 316 of MHLW, and became effective on October 1,
2007.

Numbers of discussions in the panels to prepare the supplement drafts were as follows: Panel on Principles of Revisions (7); Sub-panel on Principles of Revision (6), Panel on Medicinal Chemicals (33, including the working group); Panel on Antibiotics (9); Panel on Biologicals (8); Panel on Crude Drugs (17); Panel on Pharmaceutical Excipients (7); Panel on Physico-Chemical Methods (12); Panel on Preparations (10); Panel on Physico-Chemical Methods (8); Panel on Biological Tests (7); Panel on Nomenclature (9); Panel on International Harmonization (2); and Panel on Pharmaceutical Water (7).

It should be noted that in the preparation of the drafts for the supplement, generous cooperation was given by the Technical Committee of the Pharmaceutical Manufacturer’s Association of Osaka and of Tokyo, the Tokyo Crude Drugs Association, the Japan Pharmaceutical Excipients Council, the Japan Kampo Medicine Manufacturers’ Association, the Japan Flavor and Fragrance Materials Association, the Japan Medical Plants Federation, the Japan Pharmaceutical Manufacturers Association, and the Japan Oilseeds Processors Association.

In consequence of this revision, the JP 15th Edition carries 1567 articles, owing to the addition of 90 articles and the deletion of 6 articles.

Draft revisions covering subjects, the addition of specification “Diethylene glycol and related substances” to the Purity of both monographs Glycerin and Concentrated Glycerin was examined by the Committee on JP in September 2007, followed by PAFSC in October 2007, and then submitted to the Minister of Health, Labour and Welfare.

This revision was promulgated on February 21, 2008 by Ministerial Notification No. 32 of MHLW, and became effective.

Draft revisions covering subjects, the addition of specification “Over-sulfated chondroitin sulfate” to the Purity of monograph Heparin Sodium and the resultant addition of Over-sulfated Chondroitin Sulfate Reference Standard to the list of Reference Standards in the General Tests were examined by the Committee on JP in July 2008, followed by PAFSC in October 2008, and then submitted to the Minister of Health, Labour and Welfare.

This revision was promulgated on March 31, 2009 by Ministerial Notification No. 190 of MHLW, and became effective.

Draft revisions covering subjects in General Rules for Crude Drugs, General Tests and Monographs, for which discussions were completed between April 2007 and March 2009, were prepared for a supplement to the JP 15. They were examined by the Committee on JP in April 2009, followed by PAFSC in June 2009, and then submitted to the Minister of Health, Labour and Welfare.

The supplement was named “Supplement II to JP 15th Edition” and promulgated on September 30, 2009 by Ministerial Notification No. 425 of MHLW, and became effective on October 1, 2009.

Numbers of discussions in the panels to prepare the revision drafts were as follows: Panel on Principles of Revisions (3); Panel on Medicinal Chemicals (23); Panel on Antibiotics (8); Panel on Biologicals (8); Panel on Crude Drugs (21); Panel on Pharmaceutical Excipients (10); Panel on Physico-Chemical Methods (11, including the working group); Panel on Preparations (19, including the working group); Panel on Physico-Chemical Methods (9); Panel on Biological Tests (9); Panel on Nomenclature (6); Panel on International Harmonization (3); and Panel on Pharmaceutical Water (8).

It should be noted that in the preparation of the drafts for the supplement, generous cooperation was given by the Technical Committee of the Pharmaceutical Manufacturer’s Association of Osaka and of Tokyo, the Tokyo Crude Drugs Association, the Japan Pharmaceutical Excipients Council, the Home Medicine Association of Japan, the Japan Kampo Medicine Manufacturers’ Association, the Japan Flavor and Fragrance Materials Association, the Japan Medical Plants Federation, the Japan Parental Drug Association, the Japan Reagent Association, the Japan Oilseeds Processors Association, and the Association of Membrane Separation Technology of Japan.

In consequence of this revision, the JP 15th Edition carries 1673 articles, owing to the addition of 106 articles and the deletion of 1 article.

Draft revisions covering subjects, the revision of the General Tests connected with the harmonization between the three pharmacopoeias, JP, EP and USP, the revision of the specification of monograph Longgu and the addition of a monograph Powdered Longgu were examined by the Committee on JP in December 2008, followed by PAFSC in March 2009, and then submitted to the Minister of Health, Labour and Welfare.

This revision was promulgated on March 31, 2009 by Ministerial Notification No. 190 of MHLW, and became effective.

Draft revisions covering subjects in General Rules for Crude Drugs, General Tests and Monographs, for which discussions were completed between April 2007 and March 2009, were prepared for a supplement to the JP 15. They were examined by the Committee on JP in April 2009, followed by PAFSC in June 2009, and then submitted to the Minister of Health, Labour and Welfare.

The supplement was named “Supplement II to JP 15th Edition” and promulgated on September 30, 2009 by Ministerial Notification No. 425 of MHLW, and became effective on October 1, 2009.

Numbers of discussions in the panels to prepare the revision drafts were as follows: Panel on Principles of Revisions (3); Panel on Medicinal Chemicals (23); Panel on Antibiotics (8); Panel on Biologicals (8); Panel on Crude Drugs (21); Panel on Pharmaceutical Excipients (10); Panel on Physico-Chemical Methods (11, including the working group); Panel on Preparations (19, including the working group); Panel on Physico-Chemical Methods (9); Panel on Biological Tests (9); Panel on Nomenclature (6); Panel on International Harmonization (3); and Panel on Pharmaceutical Water (8).

It should be noted that in the preparation of the drafts for the supplement, generous cooperation was given by the Technical Committee of the Pharmaceutical Manufacturer’s Association of Osaka and of Tokyo, the Tokyo Crude Drugs Association, the Japan Pharmaceutical Excipients Council, the Home Medicine Association of Japan, the Japan Kampo Medicine Manufacturers’ Association, the Japan Flavor and Fragrance Materials Association, the Japan Medical Plants Federation, the Japan Parental Drug Association, the Japan Reagent Association, the Japan Oilseeds Processors Association, and the Association of Membrane Separation Technology of Japan.

In consequence of this revision, the JP 15th Edition carries 1673 articles, owing to the addition of 106 articles and the deletion of 1 article.

Draft revisions covering subjects, the revision of the General Tests connected with the harmonization between the three pharmacopoeias, JP, EP and USP, the revision of the specification of monograph Longgu and the addition of a monograph Powdered Longgu were examined by the Committee on JP in December 2008, followed by PAFSC in March 2009, and then submitted to the Minister of Health, Labour and Welfare.

This revision was promulgated on March 31, 2009 by Ministerial Notification No. 190 of MHLW, and became effective.
revision in the Purity of two monographs Heparin Calcium and Heparin Sodium, and the several additions to the Reference Standards and the Reagents, Test Solutions were examined by the Committee on JP in August 2009, followed by PAFSC in September 2009, and then submitted to the Minister of Health, Labour and Welfare.

This revision was promulgated on July 30, 2010 by Ministerial Notification No. 322 of MHLW, and became effective.

Draft revisions covering subjects in General Notices, General Rules for Crude Drugs, General Rules for Preparations, General Tests and Monographs, for which discussions were completed between April 2009 and March 2010, were prepared for JP 16. They were examined by the Committee on JP in September 2010, followed by PAFSC in October 2010, and then submitted to the Minister of Health, Labour and Welfare.

Numbers of discussions in the panels to prepare the revision drafts were as follows: Panel on Principles of Revisions (3); Panel on Medicinal Chemicals (20); Panel on Antibiotics (5); Panel on Biologicals (2); Panel on Crude Drugs (10); Panel on Pharmaceutical Excipients (5); Panel on Physico-Chemical Methods (10, including the working group); Panel on Preparations (10, including the working group); Panel on Physico-Chemical Methods (8); Panel on Biological Tests (9, including the working group); Panel on Nomenclature (3); Panel on International Harmonization (1); and Panel on Pharmaceutical Water (4).

It should be noted that in the preparation of the drafts, generous cooperation was given by the Technical Committee of the Pharmaceutical Manufacturer’s Association of Osaka and of Tokyo, the Tokyo Crude Drugs Association, the Japan Pharmaceutical Excipients Council, the Home Medicine Association of Japan, the Japan Kampo Medicine Manufacturers’ Association, the Japan Flavor and Fragrance Materials Association, the Japan Medical Plants Federation, the Japan Parental Drug Association, the Japan Reagent Association, the Japan Oilseeds Processors Association, and the Association of Membrane Separation Technology of Japan.

In consequence of this revision, the JP 16th Edition carries 1764 articles, owing to the addition of 106 articles and the deletion of 15 articles.

The principles of description and the salient points of the revision in this volume are as follows:

1. The JP 16th Edition comprises the following items, in order: Notification of MHLW; Contents; Preface; General Notices; General Rules for Crude Drugs; General Rules for Preparations; General Tests, Processes and Apparatus; Official Monographs; then followed by Infrared Reference Spectra and Ultraviolet-visible Reference Spectra; General Information; Table of Standard Atomic Weights 2010 as an appendix; and a Cumulative Index.

2. The articles in General Rules for Preparations, Official Monographs, Infrared Reference Spectra and Ultraviolet-visible Reference Spectra are respectively placed in alphabetical order in principle.

3. The following items in each monograph are put in the order shown below, except that unnecessary items are omitted depending on the nature of the drug:

   (1) English title
   (2) Commonly used name(s)
   (3) Latin title (only for crude drugs)
   (4) Title in Japanese
   (5) Structural formula or empirical formula
   (6) Molecular formula and molecular mass
   (7) Chemical name
   (8) CAS Registry Number
   (9) Origin
   (10) Limits of the content of the ingredient(s) and/or the unit of potency
   (11) Labeling requirements
   (12) Method of preparation
   (13) Description/Description of crude drugs
   (14) Identification tests
   (15) Specific physical and/or chemical values
   (16) Purity tests
   (17) Loss on drying or Ignition, or Water
   (18) Residue on ignition, Total ash or Acid-insoluble ash
   (19) Tests being required for pharmaceutical preparations and other special tests
   (20) Isomer ratio
   (21) Assay or the content of the ingredient(s)
   (22) Containers and storage
   (23) Expiration date
   (24) Others

4. In each monograph, the following physical and chemical values representing the properties and quality of the drug are given in the order indicated below, except that unnecessary items are omitted depending on the nature of drug:

   (1) Alcohol number
   (2) Absorbance
   (3) Congealing point
   (4) Refractive index
   (5) Osmolarity
   (6) Optical rotation
   (7) Viscosity
(8) pH
(9) Specific gravity
(10) Boiling point
(11) Melting point
(12) Acid value
(13) Saponification value
(14) Ester value
(15) Hydroxyl value
(16) Iodine value

5. Identification tests comprise the following items, which are generally put in the order given below:

(1) Coloration reactions
(2) Precipitation reactions
(3) Decomposition reactions
(4) Derivatives
(5) Infrared and/or ultraviolet-visible absorption spectrometry
(6) Special reactions
(7) Cations
(8) Anions

6. Purity tests comprise the following items, which are generally put in the order given below, except that unnecessary items are omitted depending on the nature of drug:

(1) Color
(2) Odor
(3) Clarity and/or color of solution
(4) Acidity or alkalinity
(5) Acidity
(6) Alkalinity
(7) Chloride
(8) Sulfate
(9) Sulfite
(10) Nitrate
(11) Nitrite
(12) Carbonate
(13) Bromide
(14) Iodide
(15) Soluble halide
(16) Thiocyanate
(17) Selenium
(18) Cationic salts
(19) Ammonium
(20) Heavy metals
(21) Iron
(22) Manganese
(23) Chromium
(24) Bismuth
(25) Tin
(26) Aluminum
(27) Zinc
(28) Cadmium
(29) Mercury
(30) Copper
(31) Lead
(32) Silver
(33) Alkaline earth metals
(34) Arsenic
(35) Foreign matters
(36) Related substances
(37) Residual solvent
(38) Other impurities
(39) Readily carbonizable substances

7. The following paragraphs of General Notices were revised:

(1) Paragraph 3: The sentence “The distinction of the preparations name of Fine Granules and Powders follows according to the definition in the section of "Powders" of General Rules for Preparations.” was deleted according to the revision of General Rules for Preparations.

(2) Paragraph 4: Exampled name of preparations was revised in accordance with the current status of listed monographs.

(3) Paragraph 8: Atomic masses the JP refers to was revised to the table of “Standard Atomic Weights 2010”.

(4) Paragraph 9: Being often used two units, pS cm\(^{-1}\) and CFU, were added.

(5) Paragraph 16: The definition of water used to measure the number of drops of a dropping device was revised in accordance with the revision of Paragraph 20.

(6) Paragraph 20: The provision of water used for the test of drugs was revised according to the revision of monograph Purified Water.

(7) Other descriptions were improved.

8. To Paragraph 1 of General Rules for Crude Drugs the following items were added:

(1) Aluminum Silicate Hydrate with Silicon Dioxide
(2) Brown Rice
(3) Koi
(4) Sesame

9. The General Rules for Preparations was revised as follows in general:

The addition of dosage forms which had not have been prescribed, the classification of dosage forms based on the route and/or site of administration, and the definition of individual dosage forms and the tests to be applied to them.

10. The following items in General Tests, Processes and Apparatus were revised:
(1) 2.01 Liquid Chromatography
(2) 2.46 Residual Solvents Test
(3) 2.51 Conductivity Measurement
(4) 2.54 pH Determination
(5) 2.58 X-Ray Powder Diffraction Method
(6) 3.01 Determination of Bulk and Tapped Densities
(7) 4.01 Bacterial Endotoxins Test
(8) 4.05 Microbial Limit Test
(9) 4.06 Sterility Test
(10) 5.02 Microbial Limit Test for Crude Drugs
(11) 6.03 Particle Size Distribution Test for Preparations
(12) 6.07 Insoluble Particulate Matter Test for Injections
(13) 6.08 Insoluble Particulate Matter Test for Ophthalmic Solutions
(14) 7.02 Test Methods for Plastic Containers
(15) 8.01 Sterilization and Aseptic Manipulation

11. The title of the following item in General Tests, Processes and Apparatus was revised: 8.01 Sterilization and Aseptic Manipulation

12. The following Reference Standards were added:
   - Atorvastatin Calcium
   - Alendronate Sodium
   - Glimepiride
   - Sarpogrelate Hydrochloride
   - Donepezil Hydrochloride
   - Trehalose
   - Nateglinide
   - Fexofenadine Hydrochloride
   - Fluvoxamine Maleate
   - Propiverine Hydrochloride
   - Pemirolast Potassium
   - Rabeprazole Sodium
   - Risedronic Acid

13. The following Reference Standard was revised in Japanese title:
   - Tyrosine

14. The following Reference Standards were deleted from the list of 9.01 Reference Standards:
   - Astromicin Sulfate
   - Insulin
   - Sisomicin Sulfate
   - Cefapirin Sodium
   - Cefuroxime Sodium
   - Netilmicin Sulfate

15. The intended use of each individual Reference Standard was deleted from the list of 9.01 Reference Standards.

16. Some of the names of the reagents or test solutions under 9.41 Reagents, Test Solutions were maintained.

17. To the each individual item in the General Tests, Processes and Apparatus, chapter and section numbers were putted.

18. The following substances were newly added to the Official Monographs:
   - Aciclovir Syrup
   - Aciclovir Injection
   - Aciclovir for Syrup
   - Acetylcysteine
   - Atorvastatin Calcium Hydrate
   - Atorvastatin Calcium Tablets
   - Alendronate Sodium Sulfate for Injection
   - Alendronate Sodium Tablets
   - Alendronate Sodium Tablets
   - L-Isoleucine, L-Leucine and L-Valine Granules
   - Ebastine
   - Ebastine Orally Disintegrating Tablets
   - Ebastine Tablets
   - Carvedilol
   - Carvedilol Tablets
   - Candesartan Cilexetil
   - Candesartan Cilexetil Tablets
   - Quinapril Hydrochloride
   - Quinapril Hydrochloride Tablets
   - Glimepiride
   - Glimepiride Tablets
   - L-Glutamic acid
   - Sarpogrelate Hydrochloride
   - Sarpogrelate Hydrochloride Fine Granules
   - Sarpogrelate Hydrochloride Tablets
   - Diazepam Tablets
   - Purified Water in Containers
   - Sterile Water for Injection in Containers
   - Spironolactone Tablets
   - Zolpidem Tartrate Tablets
   - Tamsulosin Hydrochloride Extended-release Tablets
   - Tamoxifen Citrate
   - Precipitated Calcium Carbonate Fine Granules
   - Precipitated Calcium Carbonate Tablets
   - Temocapril Hydrochloride
   - Temocapril Hydrochloride Tablets
   - Terbinafine Hydrochloride
   - Terbinafine Hydrochloride Cream
   - Terbinafine Hydrochloride Solution
   - Terbinafine Hydrochloride Spray
   - Doxazosin Mesilate Tablets
Donepezil Hydrochloride
Donepezil Hydrochloride Fine Granules
Donepezil Hydrochloride Tablets
Trehalose Hydrate
Nateglinide
Nateglinide Tablets
L-Lactic Acid
Sodium L-Lactate Solution
Halooperidol Fine Granules
Pioglitazone Hydrochloride Tablets
L-Histidine
L-Histidine Hydrochloride Hydrate
Famotidine Injection
Fexofenadine Hydrochloride
Butenafine Hydrochloride
Butenafine Hydrochloride Cream
Butenafine Hydrochloride Solution
Butenafine Hydrochloride Spray
Pravastatin Sodium Fine Granules
Pravastatin Sodium Solution
Pravastatin Sodium Tablets
Fluconazole
Fluvoxamine Maleate
Fluvoxamine Maleate Tablets
Flecainide Acetate
Flecainide Acetate Tablets
Propiverine Hydrochloride
Propiverine Hydrochloride Tablets
Probucol Fine Granules
Probucol Tablets
L-Proline
Betamipron
Pemirolast Potassium
Pemirolast Potassium for Syrup
Pemirolast Potassium Tablets
Beraprost Sodium
Beraprost Sodium Tablets
Mupirocin Calcium Ointment
Methotrexate Capsules
Mosapride Citrate Powder
Rabeprazole Sodium
Risperidone
Risperidone Fine Granules
Risperidone Oral Solution
Risperidone Tablets
Sodium Risedronate Hydrate
Sodium Risedronate Tablets
Roxatidine Acetate Hydrochloride Extended-release Tablets
Roxatidine Acetate Hydrochloride for Injection
Orenegedokuto Extract
Aluminum Silicate Hydrate with Silicon Dioxide
Koi
Brown Rice
Sesame
Saikokeishito Extract
Saibokuto Extract
Shakuyakukanzoto Extract
Juzentaihoto Extract
Shosaikoto Extract
Shoisyryuto Extract
Muko-Daikenchuto Extract
Chutosan Extract
Bakumondoto Extract
Rikkunshito Extract

19. The following monographs were revised:
Zinc Oxide Ointment
Ajmaline Tablets
Ascorbic Acid Powder
Ascorbic Acid Injection
Aspirin Tablets
Acetylcholine Chloride for Injection
Azelaic Acid Hydrochloride Granules
Adrenalin
Adrenalin Solution
Opium Tincture
Opium Alkaloids Hydrochloride Injection
Opium Alkaloids and Atropine Injection
Opium Alkaloids and Scopolamine Injection
Weak Opium Alkaloids and Scopolamine Injection
Meglumine Sodium Amidotrizoate Injection
Amitriptyline Hydrochloride Tablets
Aminophylline Injection
L-Alanine
L-Arginine Hydrochloride Injection
Allopurinol
Sulfur and Camphor Lotion
Sodium Iotalamate Injection
Meglumine Iotalamate Injection
Isoniazid Injection
Isoniazid Tablets
Idoxuridine Ophthalmic Solution
Imipramine Hydrochloride
Irsgladine Maleate Fine Granules
Indigocarmine Injection
Insulin Human (Genetical Recombination)
Indometacin Capsules
Indometacin Suppositories
Ursodeoxycholic Acid Granules
Ecabet Sodium Granules
Estradiol Benzoate Injection
Estradiol Benzoate Injection (Aqueous Suspension)
Estriol Tablets
Estriol Injection (Aqueous Suspension)
Etacrynic Acid Tablets
Ethanol for Disinfection
Etizolam Fine Granules
Ethinyleradiol
Ethinyleradiol Tablets
Etilefrine Hydrochloride Tablets
Edrophonium Chloride Injection
Ephedrine Hydrochloride Injection
Ephedrine Hydrochloride Tablets
10% Ephedrine Hydrochloride Powder
Ergometrine Maleate Hydrochloride Injection
Ergometrine Maleate Hydrochloride Tablets
10% Sodium Chloride Injection
Hydrochloric Acid Lemonade
Compound Oxycodone Injection
Compound Oxycodone and Atropine Injection
Fructose Injection
Potash Soap
Carmellose
Carmellose Calcium
Carmellose Sodium
Xylitol Injection
Diagnostic Sodium Citrate Solution
Sodium Citrate Injection for Transfusion
Glycerin and Potash Solution
Absorptive Cream
Hydrophilic Cream
Clindamycin Hydrochloride
Cresol Solution
Saponated Cresol Solution
Clobifbrate Capsules
Clomifene Citrate Tablets
Chlordiazepoxide Powder
Chlordiazepoxide Tablets
Chlorpheniramine Maleate Powder
Chlorpheniramine Maleate Tablets
Chlorpropamide Tablets
Chlorpromazine Hydrochloride Injection
Ketoconazole Solution
Ketoconazole Cream
10% Codeine Phosphate Powder
Codeine Phosphate Tablets
Compound Salicylic Acid Spirit
Oxygen
Diazepam
Digitoxin Tablets
Diclofenamide Tablets
Distigmine Bromide Tablets
Dydrogesterone Tablets
Zinostatin Stimalamer
1% Dihydrocodeine Phosphate Powder
Dimenhydrinate Tablets
Silver Nitrate Ophthalmic Solution
Water
Purified Water
Sterile Purified Water in Containers
Water for Injection
Dried Aluminum Hydroxide Gel Fine Granules
Suxamethonium Chloride Injection
Suxamethonium Chloride for Injection
Spironolactone
Sulpyrine Injection
Sulfobromophthalein Sodium Injection
Isotonic Sodium Chloride Solution
Cefaclor
Cefaclor Compound Granules
Cefaclor Fine Granules
Cefazolin Sodium Hydrate
Cefatrizine Propylene Glycolate for Syrup
Cefalexin
Cefalexin for Syrup
Cefalotin Sodium
Cefixime Hydrate
Cefepime Dihydrochloride Hydrate
Cefcapene Pivoxil Hydrochloride Hydrate
Cefcapene Pivoxil Hydrochloride Fine Granules
Cefitoren Pivoxil Fine Granules
Cefdinir Fine Granules
Ceftibuten Hydrate
Cefteram Pivoxil Fine Granules
Cefpodoxime Proxetil
Cefroxadine for Syrup
Sevoflurane
D-Sorbitol Solution
Tacrolimus Hydrate
Talc
Sodium Bicarbonate Injection
Simple Syrup
Thiamazole Tablets
Thiamine Chloride Hydrochloride Powder
Thiamine Chloride Hydrochloride Injection
Thiopental Sodium for Injection
Sodium Thiosulfate Injection
Nitrogen
Tipepidine Hibenzate Tablets
L-Tyrosine
Testosterone Enanthate Injection
Deslanoside Injection
Dehydrocholic Acid Injection
Dopamine Hydrochloride Injection
Triclofos Sodium Syrup
Trihexyphenidyl Hydrochloride Tablets
Trimethadione Tablets
Tolnaftate Solution
Tolbutamide Tablets
Droxidopa Fine Granules
Troxipide Fine Granules
Rape Seed Oil
Naphazoline and Chlorpheniramine Solution
Nicardipine Hydrochloride Injection
Nicotinic Acid Injection
Nicomol Tablets
Carbone Dioxide
Nicergoline Powder
Nitroglycerin Tablets
Neostigmine Methylsulfate Injection
Noradrenaline Injection
Norgestrel and Ethinylestradiol Tablets
Baclofen Tablets
Papaverine Hydrochloride Injection
Calcium Paraaminosalicylate Granules
Busacodyl Suppositories
Hydralazine Hydrochloride Powder
Hydralazine Hydrochloride Tablets
Hydralazine Hydrochloride for Injection
Piperazine Phosphate Tablets
Famotidine Powder
Faropenem Sodium for Syrup
Phenytoin Powder
Phenytoin Tablets
Phenobarbital
10% Phenobarbital Powder
Liquefied Phenol
Phenolated Water
Phenolated Water for Disinfection
Phenol and Zinc Oxide Liniment
Phenolsulfonphthalein Injection
Glucose Injection
Prazepam Tablets
Flurazepam Capsules
Prednisolone Tablets
Prednisolone Sodium Succinate for Injection
Procaine Hydrochloride Injection
Prochlorperazine Maleate Tablets
Propylthiouracil Tablets
Flopropione Capsules
Probenecid
Probenecid Tablets
Flomoxef Sodium
Betamethasone Valerate and Gentamicin Sulfate Cream
Betamethasone Sodium Phosphate
Pethidine Hydrochloride Injection
Perphenazine Tablets
Perphenazine Maleate Tablets
Benzalkonium Chloride Solution
Benyl Alcohol
Benzethonium Chloride Solution
Formalin Water
Mercurochrome Solution
D-Mannitol Injection
Yellow Beeswax
Minocycline Hydrochloride
Minocycline Hydrochloride Tablets
Minocycline Hydrochloride for Injection
Alum Solution
10% dl-Methylephedrine Hydrochloride Powder
Methyltestosterone Tablets
Metyldopa Tablets
Metenolone Enanthate Injection
Metronidazole Tablets
Mepivacaine Hydrochloride
Mefruside Tablets
Meropenem Hydrate
Morphine Hydrochloride Tablets
Morphine Hydrochloride Injection
Morphine and Atropine Injection
Folic Acid Tablets
Folic Acid Injection
Meglumine Sodium Iodamide Injection
Iodine Tincture
Dilute Iodine Tincture
Dental Iodine Glycerin
Compound Iodine Glycerin
Iodine, Salicylic Acid and Phenol Spirit
Latomoxef Sodium
Lanatoside C Tablets
Liothyronine Sodium Tablets
L-Lysine Hydrochloride
L-Lysine Acetate
Lidocaine Injection
Rifampicin Capsules
Riboflavin Powder
Riboflavin Sodium Phosphate Injection
Zinc Sulfate Ophthalmic Solution
Magnesium Sulfate Mixture
Magnesium Sulfate Injection
Ringer’s Solution
Dibasic Sodium Phosphate Hydrate
Reserpine Tablets
Reserpine Injection
Levallorphan Tartrate Injection
Levothyroxine Sodium Tablets
Sweet Hydrangea Leaf
Aloe
Powdered Aloe
Foeniculated Ammonia Spirit
Epimedium Herb
Fennel Oil
Turmeric
Powdered Turmeric
Bearberry Leaf
Uva Ursi Fluidextract
Corydalis Tuber
Powdered Corydalis Tuber
Polygala Root
Powdered Polygala Root
Pueraria Root
Kamishoyosan Extract
Glycyrrhiza Extract
Crude Glycyrrhiza Extract
Agar
Platycodeon Fluidextract
Catalpa Fruit
Apricot Kernel
Apricot Kernel Water
Bitter Tincture
Keishibukuryogan Extract

Glehnia Root and Rhizome
Hangekobokuto Extract
Angelica Dahurica Root
Atractylodes Rhizome
Poria Sclerotium
Belladonna Extract
Sinomenium Stem and Rhizome
Saposhnikovia Root and Rhizome
Moutan Bark
Powdered Moutan Bark
Hochuekkito Extract
Nux Vomica Extract
Nux Vomica Extract Powder
Nux Vomica Tincture
Oyster Shell
Powdered Oyster Shell
Ryokejutsukanto Extract
Scopolia Extract
Scopolia Extract Powder
Royal Jelly

20. The following monographs were deleted:
Astromicin Sulfate
Isophane Insulin Injection (Aqueous Suspension)
Insulin
Insulin Injection
Insulin Zinc Injection (Aqueous Suspension)
Insulin Zinc Protamine Injection (Aqueous Suspension)
Crystalline Insulin Zinc Injection (Aqueous Suspension)
Amorphous Insulin Zinc Injection (Aqueous Suspension)
Sisomicin Sulfate
Cefapirin Sodium
Cefuroxime Sodium
Netilmicin Sulfate
Bufexamac
Bufexamac Cream
Bufexamac Ointment

21. The following monographs were changed in Japanese title:
Absorptive Cream
Hydrophilic Cream
Sterile Purified Water in Containers
Cefixime Hydrate
L-Tyrosine
L-Lysine Hydrochloride
L-Lysine Acetate

22. The following monographs were revised in the content limit more precise:
Ajmaline Tablets
Ascorbic Acid Powder
Ascorbic Acid Injection
Aspirin Tablets
Acetylcholine Chloride for Injection
Meglumine Sodium Amidotrizoate Injection
Amitriptyline Hydrochloride Tablets
Aminophylline Injection
Sodium Iotalamate Injection
Meglumine Iotalamate Injection
Amitrazine Tablets
Isoniazid Tablets
Isoniazid Injection
Idoxuridine Ophthalmic Solution
Imipramine Hydrochloride
Indigocarmine Injection
Indomethacin Capsules

23. The monographs which ‘Method of preparation’ was revised according to the revision of General Rules for Preparations were as follows:

Ascorbic Acid Powder  
Irsogladine Maleate Fine Granules  
Etizolam Fine Granules  
10% Ephedrine Phosphate Powder  
Chlordiazepoxide Powder  
Chlorpheniramine Maleate Powder  
Ketoconazole Solution  
Ketoconazole Cream  
1% Codeine Phosphate Powder  
1% Dihydrocodeine Phosphate Powder  
Dried Aluminum Hydroxide Gel Fine Granules  
Cefaclor Fine Granules  
Ceftriazine Propylene Glycolate for Syrup  
Cefalexin for Syrup  
Cefcapene Pivoxil Hydrochloride Fine Granules  
Cefditoren Pivoxil Fine Granules  
Cefdinir Fine Granules  
Ceferam Pivoxil Fine Granules  
Cefroxadine for Syrup  
Droxicidopa Fine Granules  
Troxipide Fine Granules  
Nicergoline Powder  
Hydralazine Hydrochloride Powder  
Famotidine Powder  
Faropenem Sodium for Syrup  
Phenytoin Powder  
10% Phenobarbital Powder  
Betamethazone Valerate and Gentamicin Sulfate Cream  
10% dl-Methylephedrine Hydrochloride Powder  
Riboflavin Powder  

24. The monographs which ‘Particle size’ was deleted according to the revision of General Rules for Preparations were as follows:

Azelastine Hydrochloride Granules  
Ursodeoxycholic Acid Granules  
Ecabet Sodium Granules  
Chlorpheniramine Maleate Powder  
Cefaclor Compound Granules  
Nicergoline Powder  
Calcium Paraaminosalicylate Granules  
10% Phenobarbital Powder  

25. The monographs which ‘Method of preparation’ was revised according to the revision of the monograph ‘Water’ were as follows:

Adrenaline Solution  
Opium Tincture  
Opium Alkaloids Hydrochloride Injection  
Opium Alkaloids and Atropine Injection  
Opium Alkaloids and Scopolamine Injection  
Weak Opium Alkaloids and Scopolamine Injection  
Meglumine Sodium Amidotrizoate Injection  
L-Arginine Hydrochloride Injection  
Sulfur and Camphor Lotion  
Sodium Iotalamate Injection  
Meglumine Iotalamate Injection  
Ethanol for Disinfection

*: Chairman, the Committee on JP
**: Acting Chairman, the Committee on JP
1. The official name of this pharmacopoeia is 第十六改正日本薬局方, and may be abbreviated as 日局十六, 日局16, JP XVI or JP 16.
2. The English name of this pharmacopoeia is The Japanese Pharmacopoeia, Sixteenth Edition.
3. Among drugs, the Japanese Pharmacopoeia Drugs (the JP Drugs) are those specified in the monographs. The title names and the commonly used names adopted in the monographs should be used as official names. In the drug monographs, in addition to English name, chemical names or Latin names can be mentioned in the titles, as appropriate.
4. “Crude Drugs and related drugs” are placed together in the posterior part of the Official Monographs. These include: Crude Drugs being applied the requirements of the General Rules for Crude Drugs, or Powders, Extracts, Tinctures, Syrups, Spirits, Fluidextracts or Suppositories containing Crude Drugs as the active ingredient, combination preparations containing Crude Drugs as the principal active ingredient.
5. Drugs are to be tested according to the provisions given in the pertinent monographs, General Notices, General Rules for Crude Drugs, General Rules for Preparations, and General Tests for their conformity to the Japanese Pharmacopoeia. However, the items of “Description” and “Storage” under Containers and storage in the monographs on preparations are given for information, and should not be taken as indicating standards for conformity.
6. In principle, unless otherwise specified, animals used for preparing the JP Drugs or their source materials must be healthy.
7. In this English version, the JP Drugs described in the monographs begin with a capital letter.
8. The molecular formulas or constitution formulas in parentheses ( ) after the name of drugs or chemicals designate chemically pure substances. Atomic masses adopted in the Japanese Pharmacopoeia conform to the table of “Standard Atomic Weights 2010”. Molecular masses are indicated to two decimal places rounded from three decimals.
9. The following abbreviations are used for the principal units.

Note: “ppm” used in the Nuclear Magnetic Resonance Spectroscopy indicates the chemical shift, and “w/v%” is used in the formula or composition of preparations.
10. The unit used for expressing the potency of drug is recognized as the quantity of drug. Usually it is expressed by a definite quantity of a definite standard substance which shows a definite biological activity, and differs according to each drug. The units are determined, in principle, by comparison with each reference standard by means of biological methods. The term “Unit” used for the JP articles indicates the unit
defined in the Japanese Pharmacopoeia.

11. The statement "Being specified separately." in the monographs means that the tests are to be specified when the drugs are granted approval based on the Pharmaceutical Affairs Law.

12. When an assurance that a product is of the JP Drug quality is obtained consistently from data derived from the manufacturing process validation studies, and from the records of appropriate manufacturing process control and of the test results of the quality control, some of the test items in the monograph being performed for the release of a product may be omitted as occasion demands.

13. The test methods specified in the Japanese Pharmacopoeia can be replaced by alternative methods which give better accuracy and precision. However, where a difference in test results is suspected, only the result obtained by the procedure given in the Pharmacopoeia is effective for the final judgment.

14. The details of the biological test methods may be changed insofar as they do not affect the essential qualities of the test.

15. The temperature for the tests or storage is described, in principle, in specific figures. However, the following expressions may be used instead.

Standard temperature, ordinary temperature, room temperature, and lukewarm are defined as 20°C, 15 – 25°C, 1 – 30°C, and 30 – 40°C, respectively. A cold place, unless otherwise specified, shall be a place having a temperature of 1 – 15°C.

The temperature of cold water, lukewarm water, warm water, and hot water are defined as not exceeding 10°C, 30 – 40°C, 60 – 70°C, and about 100°C, respectively.

The term “heated solvent” or “hot solvent” means a solvent heated almost to the boiling point of the solvent, and the term “warmed solvent” or “warm solvent” usually means a solvent heated to a temperature between 60°C and 70°C. The term “heat on or in a water bath” indicates, unless otherwise specified, heating with a boiling water bath or a steam bath at about 100°C.

Cold extraction and warm extraction are usually performed at temperatures of 15 – 25°C and 35 – 45°C, respectively.

16. To measure the number of drops, a dropping device which delivers 20 drops of water weighing 0.90 – 1.10 g at 20°C shall be used.

17. The term “in vacuum” indicates, unless otherwise specified, a pressure not exceeding 2.0 kPa.

18. The acidity or alkalinity of a solution, unless otherwise specified, is determined by blue or red litmus papers. To indicate these properties more precisely, pH values are used.

19. The terms in Table 1 are used to express the degree of cutting of Crude Drugs or fineness of powder Drugs.

20. The water to be used in the tests of drugs shall be the water suitable for performing the relevant test, such as the water not containing any substance that would interfere with the test.

21. As for wording “solution of a solute”, where the name of the solvent is not stated, the term “solution” indicates a solution in water.

22. For solution an expression such as “(1 in 3)”, “(1 in 10)”, or “(1 in 100)” means that 1 g of a solid is dissolved in, or 1 mL of a liquid is diluted with the solvent to make the total volume of 3 mL, 10 mL or 100 mL, respectively. For the liquid mixture an expression such as “(10:1)” or “(5:3:1)” means that the respective numbers of parts, by volume, of the designated liquids are to be mixed.

23. The term “weigh accurately” means to weigh down to the degree of 0.1 mg, 0.01 mg or 0.001 mg by taking into account the purpose of the test and using a relevant weighing device. The term “weigh exactly” means to weigh to the given decimal places.

24. A value of “n” figures in a test of a JP Drug shall be obtained by rounding off a value of “n + 1” figures.

25. Unless otherwise specified, all tests of the drugs shall be performed at the ordinary temperature and observations of the results shall follow immediately after the operations. However, the judgment for a test which is affected by temperature should be based on the conditions at the standard temperature.

26. The terms “immediately”/“at once” used in the test of a JP Drug mean that the procedure is to be performed within 30 seconds after the preceding procedure.

27. In the section under the heading Description, the term “white” is used to indicate white or practically white, and “colorless” is colorless or practically colorless. Unless otherwise specified, the test of color is carried out by placing 1 g of a solid drug on a sheet of
white paper or in a watch glass placed on white paper. A liquid drug is put into a colorless test tube of 15-mm internal diameter and is observed in front of a white background through a layer of 30 mm. For the test of clarity of liquid drugs the same procedure is applied with either a black or white background. For the observation of fluorescence of a liquid drug, only a black background shall be used.

28. In the section under the heading Description, the term “odorless” is used to indicate odorless or practically odorless. Unless otherwise specified, the test of odor shall be carried out by placing 1 g of a solid drug or 1 mL of a liquid drug in a beaker.

29. In the section under the heading Description, solubilities are expressed by the terms in Table 2. Unless otherwise specified, solubility means the degree of dissolution of a JP Drug, previously powdered in the case of a solid drug, within 30 minutes in a solvent at 20 ± 5°C, by vigorous shaking for 30 seconds each time at 5-minute intervals.

30. In the test of a drug, the term “dissolve” or “miscible” indicates that it dissolves in, or mixes in arbitrary proportion with the solvent to form a clear solution or mixture. Insoluble materials other than the drug including fibers should not be detected or practically invisible, if any.

31. Identification is the test to identify the active ingredient(s) of the drug based upon its specific property.

32. Purity is the test to detect impurities/contaminants in drugs, and it, as well as other requirements in each monograph, specifies the purity of the drug usually by limiting the kind/nature and quantity of the impurities/contaminants. The impurities/contaminants subject to the purity test are those supposed to generate/contaminate during the manufacturing process or storage, including hazardous agents such as heavy metals, arsenic, etc. If any foreign substances are used or supposed to be added, it is necessary to perform tests to detect or limit the presence of such substances.

33. The term “constant mass” in drying or ignition, unless otherwise specified, means that the mass difference after an additional 1 hour of drying or ignition is not more than 0.10% of the preceding mass of the dried substance or ignited residue. For crude drugs, the difference is not more than 0.25%. However, when the difference does not exceed 0.5 mg in a chemical balance, 0.05 mg in a semi-microbalance, or 0.005 mg in a microbalance, the constant mass has been attained.

34. Assay is the test to determine the composition, the content of the active ingredients, and the potency unit of medicine by physical, chemical or biological procedures.

35. In stating the appropriate quantities to be taken for assay, the use of the word “about” indicates a quantity within 10% of the specified mass. The word “dry” in respect of the sample indicates drying under the same conditions, as described in Loss on drying in the monograph.

36. For the content of an ingredient determined by Assay in the monographs, if it is expressed simply as “not less than a certain percentage” without indicating its upper limit, 101.0% is understood as the upper limit.

37. The container is the device which holds drugs. The stopper or cap, etc., is considered as part of the container. The containers have no physical and chemical reactivity affecting the specified description and quality of the contents.

38. A well-closed container protects the contents from extraneous solids and from loss of the drug under ordinary or customary conditions of handling, shipment, and storage.

Where a well-closed container is specified, it may be replaced by a tight container.

39. A tight container protects the contents from extraneous solids or liquids, from loss of the contents, and from efflorescence, deliquescence, or evaporation under ordinary or customary conditions of handling, shipment, and storage.

Where a tight container is specified, it may be replaced by a hermetic container.

40. A hermetic container is impervious to air or any other gas under ordinary or customary conditions of handling, shipment, and storage.

41. The term “light-resistant” means that it can prevent transmittance of light affecting in the specified properties and quality of the contents and protect the
contained medicament from the light under ordinary
or customary conditions of handling, shipment, and
storage.

42. For the JP Drugs, the contents or potency in
terms of units of the active ingredient(s), or the speci-
fied expiration date in the monographs have to be
shown on the immediate container or wrapping of
them.

43. The origin, numerical value or physical proper-
ties of the JP Drugs, being stipulated by the special
labeling requirements in the monographs, have to be
shown on the immediate container or wrapping of
them.

44. The harmonized General Tests and Monographs
among the Japanese Pharmacopoeia, the European
Pharmacopoeia and the United States Pharmacopeia
are preceded by the statement as such.

The parts of the text, being not harmonized, are
surrounded by the symbols (• •).

RS: Reference Standard
TS: Test Solution
GENERAL RULES FOR CRUDE DRUGS

1. Crude drugs in the monographs include medicinal parts obtained from plants or animals, cell inclusions and secretes separated from the origins, their extracts, and minerals. General Rules for Crude Drugs and Crude Drugs Test are applicable to the following:

2. Crude drugs are usually used in the forms of whole crude drugs, cut crude drugs or powdered crude drugs.

Whole crude drugs are the medicinal parts or their ingredients prepared by drying and/or simple processes, as specified in the monographs.
Cut crude drugs are small pieces or small blocks prepared by cutting or crushing of the whole crude drugs, and also coarse, medium or fine cutting of the crude drugs in whole, and, unless otherwise specified, are required to conform to the specifications of the whole crude drugs used as original materials.

Powdered crude drugs are coarse, medium, fine or very fine powder prepared from the whole crude drugs or the cut crude drugs; usually powdered crude drugs as fine powder are specified in the monographs.

3. Unless otherwise specified, crude drugs are used in dried form. The drying is usually carried out at a temperature not exceeding 60°C.

4. The origin of crude drugs is to serve as the criteria. Such statements as 'other species of the same genus' and 'allied plants' or 'allied animals' appearing in the origin of crude drugs usually indicate plants or animals which may be used as materials for crude drugs containing the same effective constituents.

5. Description in each monograph for crude drugs usually covers the crude drug derived from its typical original plant or animal and includes statements of characteristic properties of the crude drug. As for the color, odor and solubility, apply correspondingly to the prescription of the General Notices, except the odor which is to serve as the criteria. The taste and aspects obtained by microscopic observation are to serve as the criteria.

6. Powdered crude drugs, otherwise specified, may be mixed with diluents so as to attain proper content and potency.

7. Powdered crude drugs do not contain fragments of tissues, cells, cell inclusions or other foreign matter alien to the original crude drugs or cut crude drugs.

8. Crude drugs are as free as possible from contaminants and other impurities due to molds, insects and other animals and from other foreign matters, and are required to be kept in a clean and hygienic state.

9. Crude drugs are preserved under protection from moisture and insect damage, unless otherwise specified. In order to avoid insect damage, suitable fumigants may be used to preserve crude drugs, provided that the fumigants are so readily volatilized as to be harmless at the usual dosage of the crude drugs, and such fumigants that may affect the therapeutic efficacy of the crude drugs or interfere with the testing are precluded.

10. Crude drugs are preserved in well-closed containers unless otherwise specified.
GENERAL RULES
FOR PREPARATIONS

[1] General Notices for Preparations

(1) General Notices for Preparations present general rules for pharmaceutical dosage forms.

(2) In Monographs for Preparations, dosage forms are classified mainly by administration routes and application sites, and furthermore are subdivided according to their forms, functions and characteristics.

Those preparations containing mainly crude drugs as active raw materials are described under Monographs for Preparations Related to Crude Drugs.

(3) In Monographs for Preparations and Monographs for Preparations Related to Crude Drugs, dosage forms, which are generally or widely used, are described. However, any other appropriate dosage forms may be used where appropriate. For example, a dosage form suitable for a particular application may be designated by combining an administration route and a name of a dosage form listed in these chapters.

(4) In these monographs, preparation characteristics are specified for the dosage forms. The preparation characteristics are confirmed by appropriate tests.

(5) In the case of preparations, functions that control the release rate of active substance(s) may be added for the purpose of controlling the onset and duration of therapeutic effects and/or decreasing adverse or side effects. The preparations modified in release rate must have an appropriate function of controlled release for the intended use. The added functional modification must generally be displayed on the pack insert and on the direct container or packaging of these preparations.

(6) Pharmaceutical excipients are substances other than active substances contained in preparations, and they are used to increase the utility of the active substance(s) and preparation, to make formulation process easier, to keep the product quality, to improve the usability, and so forth. Suitable excipients may be added for these purposes. The excipients to be used, however, must be pharmacologically inactive and harmless in the administered amount and must not interfere with the therapeutic efficacy of the preparations.

(7) Purified water to be used for preparations is Purified Water or Purified Water in Containers, and water for injection is Water for Injection or Water for Injection in Containers.

Vegetable oils to be used for preparations are usually edible oils listed in the Pharmacopoeia. When starch is called for, unless otherwise specified, any kind of starch listed in the Pharmacopoeia may be used.

In addition, ethanol specified in vol% is prepared by adding Purified Water or Water for Injection to ethanol at the specified vol%.

(8) Even non-sterile preparations should be prepared with precautions to prevent contamination and growth of microorganisms, and they are applied to the test of Microbial Limit Test <4.05>, if necessary.

(9) The test for Content Uniformity under the Uniformity of Dosage Units <6.02> and the Dissolution Test <6.10> are not intended to apply to the crude drug component of preparations which are prepared using crude drugs or preparations related to crude drugs as raw materials.

(10) Containers and packaging for preparations must be suitable for their proper use and for ensuring safe application, as well as for maintaining the quality of the preparations. To protect preparations that may be susceptible to oxygen in the air, deoxidants or containers made of low-gas-permeability material may be used. For preparations susceptible to degradation by moisture, packages with desiccants or moisture-proof packaging using low-moisture-permeability materials for containers may be used. For preparations susceptible to degradation by evaporation of water, containers of low-moisture-permeability material may be used.

Preparations for single-dose use are referred to as “preparations in single-dose packages”.

(11) Unless otherwise specified, preserve preparations at room temperature. Store them in light-resistant containers or packaging, if light affects the quality of the preparation.

(1) In the Monographs for Preparations, the definitions of dosage forms, manufacturing methods, test methods, containers and packaging, and storage are described.

(2) The descriptions of the test methods and the containers and packaging in these monographs are fundamental requirements, and the manufacturing methods represent commonly used methods.

1. Preparations for Oral Administration

(1) Immediate-release dosage forms are preparations showing a release pattern of active substance(s) that is not intentionally modified and is generally dependent on the intrinsic solubility of the active substance.

(2) Modified-release dosage forms are preparations showing a release pattern of active substance(s) that is suitably modified for the desired purpose by means of a specific formulation design and/or manufacturing method. Modified-release dosage forms include enteric-coated and extended-release preparations.

(i) Enteric-coated (delayed-release) preparations

Enteric-coated preparations are designed to release the bulk of the active substance(s) not in stomach but mainly in small intestine, in order to prevent degradation or decomposition of the active substance(s) in stomach or to decrease the irritation of the active substance(s) on stomach. Enteric-coated preparations are generally coated with an acid-insoluble enteric film.

(ii) Extended-release preparations

Extended-release preparations are designed to control the release rate and release period of active substance(s) and to restrict the release to appropriate sites in the gastrointestinal tracts in order to decrease the dosing frequency and/or to reduce adverse or side effects. Extended-release preparations are generally prepared by using suitable agents that prolong the release of the active substance(s).

(3) Oral dosage forms such as capsules, granules and tablets can be coated with appropriate coating agents, such as sugars, sugar alcohols, or polymers, for the purpose of enabling the ingestion easy or of preventing degradation of the active substance(s).

1-1. Tablets

(1) Tablets are solid preparations having a desired shape and size, intended for oral administration. Orally Disintegrating Tablets, Chewable Tablets, Effervescent Tablets, Dispersible Tablets and Soluble Tablets are included in this category.

(2) Tablets are usually prepared by the following procedures. Enteric-coated or extended-release tablets can be prepared by appropriate methods.

(i) Mix homogeneously active substance(s) and excipients such as diluents, binders and disintegrators, granulate with water or a binder solution by a suitable method, mix with a lubricant, and then compress into a desired shape and size.

(ii) Mix homogeneously active substance(s) and excipients such as diluents, binders, and disintegrators, and then directly compress with a lubricant, or compress after adding active substance(s) and a lubricant to granules previously prepared from excipients and then mixing homogeneously.

(iii) Mix homogeneously active substance(s) and excipients such as diluents and binders, moisten with a solvent, form into a certain shape and size or mold the mixed mass into a certain shape and size, and then dry by a suitable method.

(iv) Plain Tablets are usually prepared according to (i), (ii) or (iii).

(v) Film-coated Tablets can be prepared, usually, by coating Plain Tablets with thin films using suitable film coating agents such as polymers.

(vi) Sugar-coated Tablets can be prepared, usually, by coating Plain Tablets using suitable coating agents including sugars or sugar alcohols.

(vii) Multiple-layer Tablets can be prepared by compressing granules of different compositions to form layered tablets by a suitable method.

(viii) Pressure-coated Tablets can be prepared by compressing granules to cover inner core tablets with different compositions.

(3) Unless otherwise specified, Tablets meet the requirements of Uniformity of Dosage Units <6.02>.

(4) Unless otherwise specified, Tablets meet the requirements of Dissolution Test <6.10> or Disintegration Test <6.09>. For Effervescent tablets from which active substance(s) are dissolved before use and Soluble tablets, these tests are not required.

(5) Well-closed containers are usually used for the preparations. For preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

1-1-1. Orally Disintegrating Tablets/Orodispersible Tablets

(1) Orally Disintegrating Tablets are tablets which are quickly dissolved or disintegrated in the oral cavity.

(2) Orally Disintegrating Tablets shows an appropriate disintegration.
1-1-2. Chewable Tablets
(1) Chewable Tablets are tablets which are administered by chewing.
(2) Chewable Tablets must be in shape and size avoiding danger of suffocation.

1-1-3. Effervescent Tablets
(1) Effervescent Tablets are tablets which are quickly dissolved or dispersed with bubbles in water.
(2) Effervescent tablets are usually prepared using suitable acidic substances and carbonates or hydrogen carbonates.

1-1-4. Dispersible Tablets
(1) Dispersible Tablets are tablets which are administered after having been dispersed in water.

1-1-5. Soluble Tablets
(1) Soluble Tablets are tablets which are administered after having been dissolved in water.

1-2. Capsules
(1) Capsules are preparations enclosed in capsules or wrapped with capsule bases, intended for oral administration. Capsules are classified into Hard Capsules and Soft Capsules.
(2) Capsules are usually prepared by the following methods. Enteric-coated or extended-release capsules can be prepared by a suitable method. Coloring agents, preservatives, etc. may be added to the capsule bases.
   (i) Hard Capsules: A homogeneous mixture of active substance(s) with diluents and other suitable excipients, or granules or formed masses prepared by a suitable method, are filled into capsule shells as they are or after slight compression.
   (ii) Soft Capsules: Active substance(s) and suitable excipients (including solvents) are mixed, enclosed by a suitable capsule base such as gelatin plasticized by addition of glycerin, D-sorbitol, etc. and molded in a suitable shape and size.
(3) Unless otherwise specified, Capsules meet the requirements of Uniformity of Dosage Units <6.02>.
(4) Unless otherwise specified, Capsules meet the requirements of Dissolution Test <6.10> or Disintegration Test <6.09>.
(5) Well-closed containers are usually used for Capsules. For Capsules susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

1-3. Granules
(1) Granules are preparations prepared by granulation, intended for oral administration. Effervescent Granules are included in this category.
(2) Granules are usually prepared by the following methods. Granules can be coated using suitable coating agents if necessary. Extended-release or entericoated granules can also be prepared by a suitable method.
   (i) To powdery active substance(s) add diluents, binders, disintegrators, or other suitable excipients, mix to homogenize, and granulate by a suitable method.
   (ii) To previously granulated active substance(s) add excipients such as diluents, and mix to homogenize.
   (iii) To previously granulated active substance(s) add excipients such as diluents, and granulate by a suitable method.
(3) Among Granules, the preparations may be referred to as “Fine Granules” if, when Particle Size Distribution Test for Preparations <6.03> is performed, all granules pass through a No. 18 (850 μm) sieve, and not more than 10% of which remain on a No. 30 (500 μm) sieve.
(4) Unless otherwise specified, the Granules in single-dose packages meet the requirements of Uniformity of Dosage Units <6.02>.
(5) Unless otherwise specified, Granules comply with Dissolution Test <6.10> or Disintegration Test <6.09>. However, this provision is not to be applied to Effervescent granules, which are dissolved before use, and Disintegration Test <6.09> is not required for the Granules not more than 10% of which remain on a No. 30 (500 μm) sieve when the test is performed as directed under Particle Size Distribution Test for Preparations <6.03>.
(6) Among Granules, the particulate preparations may be referred to as “Powders” if, when the Particle Size Distribution Test for Preparations <6.03> is performed, all granules pass through a No. 18 (850 μm) sieve, and not more than 5% remain on a No. 30 (500 μm) sieve.
(7) Well-closed containers are usually used for Granules. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

1-3-1. Effervescent Granules
(1) Effervescent granules are granules which are quickly dissolved or dispersed with bubbles in water.
(2) Effervescent granules are usually prepared using suitable acidic substances and carbonates or hydrogen carbonates.

1-4. Powders
(1) Powders are preparations in powder form, intended for oral administration.
(2) Powders are usually prepared by homogene-
ously mixing active substance(s) with diluents or other suitable excipients.

3) Unless otherwise specified, the Powders in single-dose packages meet the requirements of Uniformity of Dosage Units <6.02>.

4) Unless otherwise specified, Powders meet the requirements of Dissolution Test <6.10>.

5) Well-closed containers are usually used for Powders. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

1-5. Liquids and Solutions for Oral Administration

1) Liquids and Solutions for Oral Administration are preparations in liquid form or flowable and viscous gelatinous state, intended for oral administration. Elixirs, Suspensions, Emulsions and Lemonades are included in this category.

2) Liquids and Solutions for Oral Administration are usually prepared by dissolving, emulsifying or suspending active substance(s) in Purified Water together with excipients, and by filtering if necessary.

3) For Liquids and Solutions for Oral Administration which are apt to deteriorate, prepare before use.

4) Unless otherwise specified, the preparations in single-dose packages meet the requirement of Uniformity of Dosage Units <6.02>.

5) Tight containers are usually used for Liquids and Solutions for Oral Administration. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

1-5-1. Elixirs

1) Elixirs are clear, sweetened and aromatic liquid preparations, containing ethanol, intended for oral administration.

2) Elixirs are usually prepared by dissolving solid active substance(s) or their extractives in ethanol and Purified Water, adding aromatic agents and sucrose, other sugars or sweetening agents, and clarifying by filtration or other procedure.

1-5-2. Suspensions

1) Suspensions are liquid preparations of active substance(s) suspended finely and homogeneously in a vehicle, intended for oral administration.

2) Suspensions are usually prepared by adding suspending agent or other suitable excipients and Purified Water or oil to solid active substance(s), and suspending homogeneously as the whole by a suitable method.

3) Mix homogeneously before use, if necessary.

4) Unless otherwise specified, Suspensions meet the requirements of Dissolution Test <6.10>.

1-5-3. Emulsions

1) Emulsions are liquid preparations of active substance(s) emulsified finely and homogeneously in a liquid vehicle, intended for oral administration.

2) Emulsions are usually prepared by adding emulsifying agents and Purified Water to liquid active substance(s), and emulsifying finely and homogeneously by a suitable method.

3) Mix homogeneously before use, where necessary.

1-5-4. Lemonades

1) Lemonades are sweet and sour, clear liquid preparations, intended for oral administration.

1-6. Syrups

1) Syrups are viscous liquid or solid preparations containing sugars or sweetening agents, intended for oral administration. Preparations for Syrups are included in this category.

2) Syrups are usually prepared by dissolving, mixing, suspending or emulsifying active substance(s) in a solution of sucrose, other sugars or sweetening agents, or in Simple Syrup. Where necessary, the mixture is boiled, and filtered while hot.

3) For Syrups which are apt to deteriorate, prepare before use.

4) Unless otherwise specified, Syrups in single-dose packages meet the requirements of Uniformity of Dosage Units <6.02>.

5) Unless otherwise specified, Syrups in which active substance(s) is suspended meet the requirements of Dissolution Test <6.10>.

6) Tight containers are usually used for Syrups. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

1-6-1. Preparations for Syrups

1) Preparations for Syrups are preparations in form of granules or powders, which become syrups by adding water. They may be termed "Dry Syrups".

2) Preparations for Syrup are usually prepared with sugars or sweetening agents as directed under 1-3. Granules or 1-4. Powders.

3) Preparations for Syrups are usually to be used after having been dissolved or suspended in water.

4) Unless otherwise specified, the Preparations for Syrups other than preparations which are to be used after having been dissolved meet the requirements of Dissolution Test <6.10> or Disintegration Test <6.09>. However, Disintegration Test <6.09> is not required for the Preparations, if, when the Particle Size Distribution Test for Preparations <6.03> is
performed, not more than 10% of the total amount remains on a No. 30 (500 mm) sieve.

(5) Well-closed containers are usually used for Preparations for Syrups. For the Preparations for Syrups susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

1-7. Jellies for Oral Administration

(1) Jellies for Oral Administration are non-flowable gelatinous preparations having a certain shape and size, intended for oral administration.

(2) Jellies for oral application are usually prepared by mixing active substance(s) with suitable excipients and polymer gel base, gelatinizing and forming into a certain shape and size by a suitable method.

(3) Unless otherwise specified, Jellies for Oral Administration meet the requirements of Uniformity of Dosage Units <6.02>.

(4) Unless otherwise specified, Jellies for Oral Administration meet the requirements of Dissolution Test <6.10> or show an appropriate disintegration.

(5) Tight containers are usually used for Jellies for Oral Administration. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

2. Preparations for Oro-mucosal Application

2-1. Tablets for Oro-mucosal Application

(1) Tablets for Oro-mucosal Application are solid preparations having a certain form, intended for oral cavity application.

Troches/Lozenges, Sublingual Tablets, Buccal Tablets, Mucoadhesive Tablets and Medicated Chewing Gums are included in this category.

(2) Tablets for Oro-mucosal Application are prepared as directed under 1-1. Tablets.

(3) Unless otherwise specified, Tablets for Oro-mucosal Application meet the requirements of Uniformity of Dosage Units <6.02>.

(4) Tablets for Oro-mucosal Application have an appropriate dissolution or disintegration.

(5) Well-closed containers are usually used for Tablets for Oro-mucosal Application. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

2-1-1. Troches/Lozenges

(1) Troches/Lozenges are tablets for oro-mucosal application, which are gradually dissolved or disintegrated in the mouth, and are intended for application locally to the oral cavity or the throat.

(2) Troches/Lozenges must be in shape and size avoiding danger of suffocation.

2-1-2. Sublingual Tablets

(1) Sublingual Tablets are tablets for oro-mucosal application, from which active substance(s) are quickly dissolved sublingually and absorbed via the oral mucosa.

2-1-3. Buccal Tablets

(1) Buccal Tablets are tablets for oro-mucosal application, from which the active substance(s) are dissolved gradually between the cheek and teeth, and absorbed via the oral mucosa.

2-1-4. Mucoadhesive Tablets

(1) Mucoadhesive Tablets are tablets for oro-mucosal application that are applied by adhesion to the oral mucosa.

(2) Mucoadhesive Tablets are usually prepared by using hydrophilic polymers to form hydrogel.

2-1-5. Medicated Chewing Gums

(1) Medicated Chewing Gums are tablets for oro-mucosal application, releasing active substance(s) by chewing.

(2) Medicated Chewing Gums are usually prepared using suitable gum bases such as vegetable resin, thermoplastic resin and elastomer.

2-2. Sprays for Oro-mucosal Application

(1) Sprays for Oro-mucosal Application are preparations that are applied active substance(s) by spraying into the oral cavity in mist, powder, foam or paste forms.

(2) Sprays for Oro-mucosal Application are usually prepared by the following methods:

(i) Dissolve or suspend active substance(s) and suitable excipients in a solvent, filter, where necessary, and fill into a container together with liquefied or compressed gas.

(ii) Dissolve or suspend active substance(s) and suitable excipients in a solvent, fill into a container, and fit with a pump for spraying.

(3) Unless otherwise specified, metered-dose types among Sprays for Oro-mucosal Application have an appropriate uniformity of delivered dose.

(4) Tight containers or pressure-resistant containers are usually used for Sprays for Oro-mucosal Application.

2-3. Semi-solid Preparations for Oro-mucosal Application

(1) Semi-solid Preparations for Oro-mucosal Application are preparations in cream, gel or ointment forms, intended for application to the oral mucosa.

(2) Semi-solid Preparations for Oro-mucosal Application are usually prepared by emulsifying active substance(s) together with excipients using “Purified
Water” and oil component such as petrolatum, or by homogenizing active substance(s) together with suitable excipients using polymer gel or oil and fats as the base.

(i) Creams for oro-mucosal application are prepared as directed under 11-5. Creams.

(ii) Gels for oro-mucosal application are prepared as directed under 11-6. Gels.

(iii) Ointments for oro-mucosal application are prepared as directed under 11-4. Ointments.

For Semi-solid Preparations for Oro-mucosal Application which are apt to deteriorate, prepare before use.

(3) Sufficient amounts of suitable preservatives to prevent the growth of microorganisms may be added for Semi-solid Preparations for Oro-mucosal Application filled in multiple-dose containers.

(4) Semi-solid Preparations for Oro-mucosal Application have a suitable viscosity to apply to the oral mucosa.

(5) Tight containers are usually used for Semi-solid Preparations for Oro-mucosal Application. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

2-4. Preparations for Gargle

(1) Preparations for Gargle are liquid preparations intended to apply locally to the oral and throat cavities. Solid type preparations to be dissolved in water before use are also included in this category.

(2) Preparations for Gargle are usually prepared by dissolving active substance(s) in a solvent together with suitable excipients, and filtering where necessary. The solid preparations are prepared as directed under 1-1. Tablets or 1-3. Granules.

(3) Unless otherwise specified, Preparations for Gargle in single-dose packages meet the requirements of Uniformity of Dosage Units <6.02>.

(4) Tight containers are usually used for Preparations for Gargle. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

3. Preparations for Injection

3-1. Injections

(1) Injections are sterile preparations to be administered directly into the body through skin, muscle or blood vessel, usually in form of a solution, a suspension or an emulsion of active substance(s), or of a solid that contains active substance(s) to be dissolved or suspended before use.

Parenteral Infusions, Implants/Pellets and Prolonged-Release Injections are included in this category.

(2) Injections in solution, suspension or emulsion form are usually prepared by the following methods.

(i) Dissolve, suspend or emulsify active substance(s) with or without excipients in Water for Injection or an aqueous or nonaqueous vehicle homogeneously, fill into containers for injection, seal, and sterilize.

(ii) Dissolve, suspend or emulsify active substance(s) with or without excipients in Water for Injection or an aqueous or nonaqueous vehicle, and filtrate aseptically, or prepare aseptically a homogeneous liquid, fill into containers for injection, and seal.

Every care should be taken to prevent contamination with microorganisms. The overall processes of preparing injections, from the preparation of active solution to the sterilization, should be completed as rapidly as possible, taking into consideration the composition of the injection and the storage conditions.

The concentration of active substance(s) expressed in % represents w/v%.

Injections that are to be dissolved or suspended before use and are designated in the name as “for injection” may be accompanied by a suitable vehicle to dissolve or suspend the supplied preparation (hereinafter referred to as “vehicle attached to preparation”).

(3) Injections may be prepared as Freeze-dried Injections or Powders for Injections to prevent degradation or deactivation of the active substance(s) in solution.

(i) Freeze-dried Injections

Freeze-dried Injections are usually prepared by dissolving active substance(s) with or without excipients such as diluents in Water for Injection, sterilizing the solution by aseptic filtration, filling the filtrate directly into individual containers for injection and being freeze-dried, or dividing the filtrate in special containers, being freeze-dried and transferred into individual containers for injection.

(ii) Powders for Injections

Powders for injections are usually prepared by filtrating aseptically a solution of active substance(s), obtaining powders by crystallization from the solution or mixing additionally the powders with sterilized excipients, and filling the powders into individual containers for injections.

(4) To prevent errors in the preparation with vehicles attached or administration of injections, or bacterial or foreign matter contamination, or for the purpose of urgent use, prefilled syringes or cartridges may be prepared.

(i) Prefilled Syringes for Injections
Prefilled Syringes for injections are usually prepared by dissolving, suspending or emulsifying active substance(s) with or without excipients in a vehicle, and filling into syringes.

(ii) Cartridges for Injections

Cartridges for Injections are usually prepared by dissolving, suspending or emulsifying active substance(s) with or without excipients in a vehicle, and filling into cartridges.

The cartridges are used by fixing in an injection device for exclusive use.

(5) Vehicles used in Injections or attached to preparations must be harmless in the amounts usually administered and must not interfere with the therapeutic efficacy of the active substance(s).

The vehicles are classified into the following two groups. They should meet each requirement.

(i) Aqueous vehicles: As the vehicle of aqueous injections, Water for Injection is usually used. Isotonic Sodium Chloride Solution, Ringer’s Solution, or other suitable aqueous solutions may be used instead.

Unless otherwise specified, these aqueous vehicles, other than those exclusively for intracutaneous, subcutaneous or intramuscular administration, meet the requirements of Bacterial Endotoxins Test <4.01>.

When the Bacterial Endotoxins Test <4.01> is not applicable to aqueous vehicles, the Pyrogen Test <4.04> may be applied instead.

(ii) Non-aqueous vehicles: Vegetable oils are usually used as vehicles for non-aqueous injections. These oils, unless otherwise specified, are clear at 10°C, the acid value is not more than 0.56, the saponification value is between 185 and 200, and the iodine value falls between 79 and 137. They meet the requirements of Mineral Oil Test <1.05>.

Several suitable organic solvents other than vegetable oils may be used as non-aqueous vehicles.

(6) Unless otherwise specified, any coloring agent must not be added solely for the purpose of coloring the preparations.

(7) Sodium chloride or other excipients may be added to aqueous injections to adjust them isotonic to blood or other body fluids. Acids or alkalis may be added to adjust the pH.

(8) Injections supplied in multiple-dose containers may be added sufficient amounts of suitable preservatives to prevent the growth of microorganisms.

(9) Unless otherwise specified, Injections and vehicles attached to preparations other than those used exclusively for intracutaneous, subcutaneous or intramuscular administration meet the requirements of Bacterial Endotoxins Test <4.01>. In the case where the Bacterial Endotoxins Test <4.01> is not applicable, Pyrogen Test <4.04> may be applied instead.

(10) Unless otherwise specified, Injections and vehicles attached to preparations meet the requirements of Sterility Test <4.06>.

(11) Containers of Injections are colorless and meet the requirements of Test for Glass Containers for Injections <7.01>. Where specified in individual monographs, these containers may be replaced by colored containers meeting the requirements of Test for Glass Containers for Injections <7.01> or by plastic containers for aqueous injections meeting the requirements of Test Methods for Plastic Containers <7.02>.

(12) Unless otherwise specified, rubber stoppers used for glass containers of 100 mL or more of aqueous infusions meet the requirements of Test for Rubber Closure for Aqueous Infusions <7.03>.

(13) Unless otherwise specified, Injections and vehicles attached to preparations meet the requirements of Foreign Insoluble Matter Test for Injections <6.06>.

(14) Unless otherwise specified, Injections and vehicles attached to preparations meet the requirements of Insoluble Particulate Matter Test for Injections <6.07>.

(15) Unless otherwise specified, the actual volume of Injections meets the requirements of Test for Extractable Volume of Parenteral Preparations <6.05>.

(16) Unless otherwise specified, Injections to be dissolved or suspended before use meet the requirements of Uniformity of Dosage Units <6.02>.

(17) Suspensions for injection are usually not to be injected into the blood vessels or spinal cord, and emulsions for injection are not to be injected into the spinal cord.

(18) The maximum size of particles observed in suspensions for injection is usually not larger than 150 μm, and that of particles in emulsions for injection is usually not larger than 7 μm.

(19) The following information, unless otherwise specified, must be written on the package leaflet, or the container or wrapper.

(i) In cases where the vehicle is not specified, the name of the employed vehicle, with the exception of Water for Injection, sodium chloride solution not exceeding 0.9 w/v% and those vehicles in which acids or alkalis are used in order to adjust the pH.

(ii) In case of vehicle attached to preparation, the name of the vehicle, content volume, ingredients and quantities or ratios, and a statement of the presence of the vehicle on the outer container or outer wrapper.

(iii) Name and quantity of stabilizers, preserva-
Prolonged Release Injections are injections to be used for intramuscular administration, for the purpose of releasing active substance(s) for a long period of time.

(2) Prolonged Release Injections are usually prepared by dissolving or suspending active substance(s) in a non-aqueous vehicle such as vegetable oil, or by suspending microspheres prepared with biodegradable polymers.

(3) Prolonged Release Injections have an appropriate function of controlled release.

4. Preparations for Dialysis
4-1. Dialysis Agents
(1) Dialysis Agents are preparations in liquid, or in solid which are to be dissolved before use, intended for peritoneal dialysis or hemodialysis.

They are classified into Peritoneal dialysis agents and Hemodialysis agents.

(2) Unless otherwise specified, Dialysis Agents meet the requirements of Bacterial Endotoxins Test \(<4.01\>.

(3) The solid preparations which are to be dissolved before use among Dialysis agents have an appropriate uniformity of dosage units.

4-1-1. Peritoneal Dialysis Agents
(1) Peritoneal Dialysis Agents are sterile dialysis agents, intended to be used for peritoneal dialysis.

(2) Peritoneal Dialysis Agents are usually prepared by dissolving active substance(s) with suitable excipients in a vehicle to make a certain volume, or by filling active substance(s) combined with suitable excipients in a container, and sealing it. Sterilize if necessary. Every care should be taken to prevent microbial contamination. The overall processes from preparation to sterilization for preparing the agents should be completed as rapidly as possible, taking into consideration the composition of the agents and the storage conditions. The concentration of Peritoneal dialysis agents expressed in % represents w/v%. In the case of solid preparations which are dissolved before use, prepare as directed under 1-1. Tablets or 1-3. Granules.

(3) If necessary, pH adjusting agents, isotonic agents or other excipients may be added.

(4) Unless otherwise specified, the vehicle used for Peritoneal dialysis agents is Water for Injection.

(5) Unless otherwise specified, Peritoneal Dialysis Agents meet the requirements of Sterility Test \(<4.06\>.

(6) Unless otherwise specified, Peritoneal Dialysis Agents meet the requirements of (4) Parenteral infusions under Test for Extractable Volume of Parenteral Preparations \(<6.05\>.

(7) Unless otherwise specified, Peritoneal Dialysis Agents meet the requirements of Foreign Insoluble Matter Test for Injections \(<6.06\>.

3-1-1. Parenteral Infusions
(1) Parenteral Infusions are usually injections of not less than 100 mL, intended for intravenous administration.

(2) Parenteral Infusions are mainly administered for the purpose of water supply, correction of electrolyte abnormality and nutritional support, and they are also used by mixing with other injections for treatments by continual infusion.

3-1-2. Implants/Pellets
(1) Implants/Pellets are solid or gel-like form injections, intended for subcutaneous or intramuscular administration by means of an implant device or operative treatment, for the purpose of releasing active substance(s) for a long period of time.

(2) Implants/Pellets are usually prepared in a form of pellet, microsphere or gel using biodegradable polymers.

(3) Unless otherwise specified, Implants/Pellets meet the requirements of Uniformity of Dosage Units \(<6.02\>.

(4) Implants/Pellets have an appropriate function of controlled release.

(5) Implants/Pellets are not required the requirements of Foreign Insoluble Matter Test for Injections, Insoluble Particulate Matter for Injections and Test for Extractable Volume of Parenteral Preparations.

3-1-3. Prolonged Release Injections
(1) Prolonged Release Injections are injections to be used for intramuscular administration, for the purpose of releasing active substance(s) for a long period
(8) Unless otherwise specified, Peritoneal Dialysis Agents meet the requirements of Insoluble Particulate Matter Test for Injections <6.07>.

(9) Colorless containers meeting the requirements of Test for Glass Containers for Injections <7.01> are used for Peritoneal Dialysis Agents. Where specified otherwise, the colored containers meeting the requirements of Test for Glass Containers for Injections <7.01> or the plastic containers for aqueous injections meeting the requirements of Test Methods for Plastic Containers <7.02> may be used.

(10) Unless otherwise specified, the rubber closures of the containers meet the requirements of Test for Rubber Closure for Aqueous Infusions <7.03>.

(11) Hermetic containers, or tight containers which are able to prevent microbial contamination are usually used for Peritoneal Dialysis Agents. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

4-1-2. Hemodialysis Agents

(1) Hemodialysis agents are dialysis agents to be used for hemodialysis.

(2) Hemodialysis Agents are usually prepared by dissolving active substance(s) with excipients in a vehicle to make a certain volume, or by filling active substance(s) with excipient(s) in a container. In the case of the solid preparations to be dissolved before use, prepare as directed under 1-1. Tablets or 1-3. Granules.

(3) If necessary, pH adjusting agents, isotonic agents or other excipients may be added.

(4) Unless otherwise specified, the vehicle used for Hemodialysis agents is Water for Injection or water suitable for dialysis.

(5) Tight containers which are able to prevent microbial contamination are usually used for Hemodialysis Agents. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

5. Preparations for Inhalation

5-1. Inhalations

(1) Inhalations are preparations intended for administration as aerosols to the bronchial tubes or lung. Inhalations are classified to Dry Powder Inhalers, Inhalation Liquid Preparations and Metered-dose Inhalers.

(2) For administration of Inhalations, suitable devices or apparatus are used, or they are placed in containers which have a appropriate function of inhalation device.

5-1-1. Dry Powder Inhalers

(1) Dry Powder Inhalers are preparations which deliver a constant respiratory intake, intended for administration as solid particle aerosols.

(2) Dry Powder Inhalers are usually prepared by pulverizing active substance(s) into fine particles. Where necessary, lactose or other suitable excipients are added to make homogenous mixture.

(3) Metered-dose types among Dry Powder Inhalers have an appropriate uniformity of delivered dose of the active substance(s).

(4) The particles of active substance(s) in Dry Powder Inhalers have an aerodynamically appropriate size.

(5) Well-closed containers are usually used for Dry Powder Inhalers. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

5-1-2. Inhalation Liquid Preparations

(1) Inhalation Liquid Preparations are liquid inhalations which are administered by an inhalation device such as operating nebulizers.

(2) Inhalation Liquid Preparations are usually prepared by mixing active substance(s) with a vehicle and suitable isotonic agents and/or pH adjusting agents to make a solution or suspension, and by filtering where necessary.

(3) Sufficient amounts of suitable preservatives may be added to Inhalation Liquid Preparations to prevent the growth of microorganisms.

(4) Tight containers are usually used for Inhalation Liquid Preparations. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

5-1-3. Metered-dose Inhalers

(1) Metered-dose Inhalers are preparations which deliver a constant dose of active substance(s) from the container together with propellant filled in.

(2) Metered-dose Inhalers are usually prepared by dissolving active substance(s) with a suitable dispersing agents and stabilizers in a vehicle to make a solution or suspension, and by filling in pressure-resistant containers together with liquid propellant, and setting metering valves.

(3) Metered-dose Inhalers have an appropriate uniformity of delivered dose of active substance(s).

(4) Particles of active substance(s) in Metered-dose Inhalers have an aerodynamically appropriate size.

(5) Pressure-resistant and hermetic containers are usually used for Metered-dose Inhalers.

6. Preparations for Ophthalmic Application

6-1. Ophthalmic Liquids and Solutions
(1) Ophthalmic Liquids and Solutions are sterile preparations of liquid, or solid to be dissolved or suspended before use, intended for application to the conjunctival sac or other ocular tissues.

(2) Ophthalmic Liquids and Solutions are usually prepared by dissolving, suspending active substance(s) in a vehicle after adding excipients to make a constant volume, or mixing active substance(s) and excipients, and filling into containers. The overall processes, from preparation to sterilization, should be completed with sufficient care to prevent microbial contamination as rapidly as possible, taking into consideration the composition of the preparations and the storage conditions. The concentration of active substance expressed in % represents w/v%.

Ophthalmic Liquids and Solutions to be dissolved or suspended before use and designated in the name as “for ophthalmic application” may be accompanied by a vehicle for dissolving or suspending the preparation (hereinafter referred to as “vehicle attached to preparation”).

(3) Vessels to prepare Ophthalmic Liquids and Solutions or vehicle attached to the preparations must be harmless in the amounts usually administered and must not interfere with the therapeutic efficacy of the active substance(s).

Vehicles for Ophthalmic Liquids and Solutions are classified into the following two groups.

(i) Aqueous vehicles: As the vehicles for the aqueous preparations Purified Water or suitable aqueous vehicles are used. For vehicles attached to the preparations sterilized Purified Water or sterilized aqueous vehicles are used.

(ii) Non-aqueous vehicles: As the vehicles for the non-aqueous preparations vegetable oils are usually used. Suitable organic solvents may be also used as the non-aqueous vehicles.

(4) Unless otherwise specified, any coloring agents must not be added solely for the purpose of coloring Ophthalmic Liquids and Solutions or vehicles attached to the preparations.

(5) Sodium chloride or other excipients may be added to Ophthalmic Liquids and Solutions to adjust them isotonic to lacrimal fluid. Acids or alkalis may be also added to adjust the pH.

(6) Unless otherwise specified, Ophthalmic Liquids and Solutions and vehicles attached to the preparations meet the requirements of Sterility Test <4.06>.

(7) Sufficient amounts of appropriate preservatives to prevent the growth of microorganisms may be added to the preparations filled in multiple dose containers.

(8) Unless otherwise specified, Ophthalmic Liquids and Solutions prepared in aqueous solutions or the vehicles attached to the preparations meet the requirements of Foreign Insoluble Matter Test for Ophthalmic Solutions <6.11>.

(9) Unless otherwise specified, Ophthalmic Liquids and Solutions and the vehicles attached to the preparations meet the requirements of Insoluble Particulate Matter Test for Ophthalmic Solutions <6.08>.

(10) The maximum particle size observed in Ophthalmic suspensions is usually not larger than 75 μm.

(11) Transparent tight containers, which do not disturb the test of Foreign Insoluble Matter Test for Ophthalmic Solutions <6.11>, are usually used for Ophthalmic Liquids and Solutions. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

6-2. Ophthalmic Ointments

(1) Ophthalmic Ointments are sterile preparations of semi-solid, intended for application to the conjunctival sac or other ocular tissues.

(2) Ophthalmic Ointments are usually prepared by mixing homogeneously solution of or finely powdered active substance(s) with petrolatum or other bases, and filling into containers. The overall processes, from preparation to sterilization, should be completed with sufficient care to prevent microbial contamination as rapidly as possible, taking into consideration the composition of the preparations and the storage conditions.

(3) Sufficient amounts of suitable preservatives may be added to Ophthalmic Ointments filled in multiple dose containers to prevent the growth of microorganisms.

(4) Unless otherwise specified, Ophthalmic Ointments meet the requirements of Sterility Test <4.06>, and unless otherwise specified, the test is carried out by the Membrane filtration method.

(5) Unless otherwise specified, Ophthalmic Ointments meet the requirements of Test for Metal Particles in Ophthalmic Ointments <6.01>.

(6) The maximum particle size of active substance(s) in Ophthalmic Ointments is usually not larger than 75 μm.

(7) Ophthalmic Ointments have a suitable viscosity for applying to the ocular tissues.

(8) Tight containers which are able to prevent microbial contamination are usually used for Ophthalmic Ointments. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.
7. Preparations for Otic Application

7-1. Ear Preparations

(1) Ear Preparations are liquid, semi-solid, or solid preparations which are to be dissolved or suspended before use, intended for application to the external or internal ear.

(2) Ear Preparations are usually prepared by filling in containers with liquids in which active substance(s) and excipients are dissolved or suspended in a vehicle to make a constant volume, or with powders in which active substance(s) and excipients are mixed. The overall processes, from preparation to sterilization, should be completed with sufficient care to prevent microbial contamination as rapidly as possible, taking into consideration the composition of the preparations and the storage conditions. The concentration of active substance of Ear Preparations expressed in % represents w/v%.

In the case where the sterile preparations are prepared, proceed as directed under 6-1. Ophthalmic Liquids and Solutions.

Ear Preparations which are to be dissolved or suspended before use and designated in the name as “for otic preparation” may be accompanied by a vehicle to dissolve or suspend (hereinafter referred to as “vehicle attached to preparation”).

(3) Vehicles used for Ear Preparations or the vehicle attached to the preparation are classified into the following two groups.

(i) Aqueous vehicles: As the vehicles for the aqueous preparations or the vehicles attached to the preparations, Purified Water or suitable aqueous vehicles are used. For the sterile preparations, Sterilized Purified Water or suitable sterilized aqueous vehicles are used as the vehicle attached to the preparations.

(ii) Non-aqueous vehicles: As the vehicles for the non-aqueous preparations vegetable oils are usually used. Suitable organic solvents may be also used as non-aqueous vehicles.

(4) Unless otherwise specified, any coloring agents must not be added solely for the purpose of coloring Ear Preparations or vehicle attached to the preparations.

(5) Sufficient amounts of suitable preservatives to prevent the growth of microorganisms may be added to the preparations filled in multiple dose containers.

(6) Unless otherwise specified, sterile Ear preparations and the vehicles attached to the sterile preparations meet the requirements of Sterility Test <4.06>.

(7) Tight containers are usually used for Ear Preparations. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

8. Preparations for Nasal Application

8-1. Nasal Preparations

(1) Nasal Preparations are preparations intended for application to the nasal cavities or nasal mucous membrane.

Nasal preparations are classified into Nasal dry powder inhalers and Nasal Liquid Preparations.

(2) Where necessary, Nasal Preparations are sprayed for inhalation by using a suitable atomizing device such as spray-pump.

(3) Unless otherwise specified, metered-dose type preparations among Nasal Preparations show the appropriate uniformity of delivered dose.

8-1-1. Nasal Dry Powder Inhalers

(1) Nasal Dry Powder Inhalers are fine powdered preparations, intended for application to the nasal cavities.

(2) Nasal Dry Powder Inhalers are usually prepared by pulverizing active substance(s) into moderately fine particles, or by mixing homogeneously with excipients where necessary.

(3) Well-closed containers are usually used for Nasal Dry Powder Inhalers. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

8-1-2. Nasal Liquids and Solutions

(1) Nasal Liquids and Solutions are liquid preparations, or solid preparations to be dissolved or suspended before use, intended for application to the nasal cavities.

(2) Nasal Liquids and Solutions are usually prepared by dissolving or suspending active substance(s) in a vehicle together with excipients, and filtering where necessary. Isotonic agents and/or pH adjusting agents may be used.

(3) Nasal Liquids and Solutions, which are to be dissolved or suspended before use and designated in the name as “for nasal application”, may be accompanied by a vehicle to dissolve or suspend.

(4) Sufficient amounts of suitable preservatives to prevent the growth of microorganisms may be added to the preparations filled in multiple dose containers.

(5) Tight containers are usually used for Nasal Liquids and Solutions. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

9. Preparations for Rectal Application

9-1. Suppositories for Rectal Application

(1) Suppositories for Rectal Application are semi-
solid preparations of a desired shape and size, intended for intrarectal application, which release active substance(s) by melting at body temperature or dissolving or dispersing gradually in the secretions.

(2) Suppositories for Rectal Application are usually prepared by mixing homogeneously active substance(s) and excipients such as dispersing agents and emulsifying agents, dissolving or suspending uniformly in a base which is liquefied by warming, filling a constant volume of the resultant material into containers, and molding it into a shape and size. Lipophilic bases or hydrophilic bases are usually used.

(3) Suppositories for Rectal Application are usually conical- or spindle-shaped.

(4) Unless otherwise specified, Suppositories for Rectal Application meet the requirements of Uniformity of Dosage Units \(<6.02\)\).

(5) Suppositories for Rectal Application show an appropriate release.

(6) Well-closed containers are usually used for Suppositories for Rectal Application. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

9-2. Semi-solid Preparations for Rectal Application

(1) Semi-solid Preparations for Rectal Application are preparations which are in a form of cream, gel or ointment intended for application to around or inside of the anus.

(2) Semi-solid Preparations for Rectal Application are usually prepared by emulsifying active substance(s) with excipients in Purified Water and oil component such as vaseline, or by homogenously mixing active substance(s) and excipients in a base of polymer gel or grease.

   (i) Creams for rectal application: Prepare as directed under 11-5. Creams.
   (ii) Gels for rectal application: Prepare as directed under 11-6. Gels.
   (iii) Ointments for rectal application: Prepare as directed under 11-4. Ointments.

For the preparations which are apt to deteriorate, prepare before use.

(3) Sufficient amounts of suitable preservatives to prevent the growth of microorganisms may be added to the Preparations filled in multiple dose containers.

(4) Semi-solid Preparations for Rectal Application have a suitable viscosity for applying to the rectum.

(5) Tight containers are usually used for Semi-solid Preparations for Rectal Application. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

9-3. Enemas for Rectal Application

(1) Enemas for Rectal Application are preparations in liquid form or viscous and gelatinous state, intended for application via the anus.

(2) Enemas for Rectal Application are usually prepared by dissolving or suspending active substance(s) in Purified Water or a suitable aqueous vehicle to make a given volume, and filling in containers. Dispersing agents, stabilizers and/or pH adjusting agents may be used.

(3) Tight containers are usually used for Enemas for Rectal Application. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

10. Preparations for Vaginal Application

10-1. Tablets for Vaginal Use

(1) Tablets for Vaginal Use are solid preparations of a desired shape and size, intended for application to the vagina, which release active substance(s) by dissolving or dispersing gradually in the secretions.

(2) Tablets for Vaginal Use are usually prepared as directed under 1-1. Tablets.

(3) Unless otherwise specified, Tablets for Vaginal Use meet the requirements of Uniformity of Dosage Units \(<6.02\)\).

(4) Tablets for Vaginal Use show an appropriate release.

(5) Well-closed containers are usually used for Tablets for Vaginal Use. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

10-2. Suppositories for Vaginal Use

(1) Suppositories for Vaginal Use are semi-solid preparations of a desired shape and size, intended for application to the vagina, which release active substance(s) by melting at body temperature or by dissolving or dispersing gradually in the secretions.

(2) Suppositories for Vaginal Use are prepared according to 9-1. Suppositories for Rectal Application.

(3) Suppositories for Vaginal Use are usually spherical or ovoid shaped.

(4) Unless otherwise specified, Suppositories for Vaginal Use meet the requirements of Uniformity of Dosage Units \(<6.02\)\).

(5) Suppositories for Vaginal Use show an appropriate release.

(6) Well-closed containers are usually used for Suppositories for Vaginal Use. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.
11. Preparations for Cutaneous Application

11-1. Solid Preparations for Cutaneous Application

1. Solid Preparations for Cutaneous Application are solid preparations intended for application to the skin (including scalp) or nails. Powders for Cutaneous Application are included in this category.

2. Unless otherwise specified, Solid Preparations for Cutaneous Application in single-dose packages meet the requirements of Uniformity of Dosage Units \(<6.02\>.

3. Well-closed containers are usually used for Solid Preparations for Cutaneous Application. For the preparations susceptible to degradation by moisture, a moisture-proof container or packaging may be used.

11-1-1. Powders for Cutaneous Application

1. Powders for Cutaneous Application are powdery solid preparations intended for external application.

2. Powders for Cutaneous Application are usually prepared by mixing homogeneously active substance(s) and excipients such as diluents and pulverizing the mixture.

11-2. Liquids and Solutions for Cutaneous Application

1. Liquids and Solutions for Cutaneous Application are liquid preparations intended for application to the skin (including scalp) or nails. Liniments and Lotions are included in this category.

2. Liquids and Solutions for Cutaneous Application are usually prepared by mixing active substance(s) with excipients in a vehicle, and filtering if necessary.

For the preparations which are apt to deteriorate, prepare before use.

3. Unless otherwise specified, Liquids and Solutions for Cutaneous Application in single-dose packages meet the requirements of Uniformity of Dosage Units \(<6.02\>\), except for emulsified or suspended preparations.

4. Tight containers are usually used for Liquids and Solutions for Cutaneous Application. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

11-2-1. Liniments

1. Liniments are liquid or muddy preparations intended for external application to the skin by rubbing.

11-2-2. Lotions

1. Lotions are external liquids in which active substance(s) are dissolved, emulsified or finely dispersed in an aqueous vehicle.

2. Lotions are usually prepared by dissolving, suspending or emulsifying active substance(s) in Purified Water with excipients and making homogeneous as a whole.

3. Lotions in which the components have separated out during storage may be used after mixing to re-homogenize them, provided that the active substance(s) has not deteriorated.

11-3. Sprays for Cutaneous Application

1. Sprays for Cutaneous Application are preparations intended for spraying active substance(s) onto the skin in mists, powders, foams or paste state.

Sprays for Cutaneous Application are classified into Aerosols for Cutaneous Application and Pump Sprays for Cutaneous Application.

2. Sprays for Cutaneous Application are usually prepared by dissolving or suspending active substance(s) in a vehicle, filtering where necessary, and filling in containers.

3. Unless otherwise specified, metered-dose type sprays show an appropriate uniformity of delivered dose.

11-3-1. Aerosols for Cutaneous Application

1. Aerosols for Cutaneous Application are sprays which atomize active substance(s) together with liquefied or compressed gas filled in containers.

2. Aerosols for Cutaneous Application are usually prepared by dissolving or suspending active substance(s) in a vehicle, filling with liquefied propellants in pressure-resistant containers, and setting a continuous spray valve. If necessary, dispersing agents and stabilizers may be used.

3. Pressure-resistant containers are usually used for Aerosols for Cutaneous Application.

11-3-2. Pump Sprays for Cutaneous Application

1. Pump Sprays for Cutaneous Application are sprays which atomize active substance(s) in containers by pumping.

2. Pump Sprays for Cutaneous Application are usually prepared by dissolving or suspending active substance(s) with excipients in a vehicle, filling in containers and setting pumps to the containers.

3. Tight containers are usually used for Pump Sprays for Cutaneous Application. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.
11-4. Ointments

(1) Ointments are semi-solid preparations to be applied to the skin, which dissolve or disperse active substance(s) in a base. There are two types, hydrophobic ointments and hydrophilic ointments.

(2) Hydrophobic ointments are usually prepared by warming to melt hydrophobic bases such as fatty oils, waxes or paraffin, adding and mixing active substance(s) in the bases to be dissolved or dispersed, and kneading the whole to make homogeneous.

Hydrophilic ointments are usually prepared by warming to melt hydrophilic bases such as macrogol, adding and mixing active substance(s) in the bases, and kneading the whole to make homogeneous.

For Ointments which are apt to deteriorate, prepare before use.

(3) Ointments have a suitable viscosity for application to the skin.

(4) Tight containers are usually used for Ointments. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

11-5. Creams

(1) Creams are semi-solid preparations to be applied to the skin, which are in the form of oil-in-water or water-in-oil emulsions. Hydrophobic preparations in the form of water-in-oil emulsions may be termed “Oily creams”.

(2) Creams are usually prepared by mixing homogenously and emulsifying an oil-phase component and a water-phase component, both warmed, of which either one contains the active substance(s). These components have the following constituents.

Oil-phase component: Vaseline, fatty alcohols, etc., with or without emulsifying agent(s) or other suitable excipients.

Water-phase component: Purified Water with or without emulsifying agent(s) or other suitable excipients.

For Creams which are apt to deteriorate, prepare before use.

(3) Creams have a suitable viscosity for applying to the skin.

(4) Tight containers are usually used for Creams. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

11-6. Gels

(1) Gels are gelatinous preparations intended for application to the skin.

There are Aqueous Gels and Oily Gels.

(2) Gels are usually prepared by the following methods.

(i) Aqueous Gels: To active substance(s) add polymers, other excipients and Purified Water, dissolve or suspend, and gelatinize by warming and cooling or by adding a gelatinizing agents.

(ii) Oily Gels: To active substance(s) add liquid oily bases such as glycols, fatty alcohols and other excipients, and mix.

(3) Gels have a suitable viscosity for application to the skin.

(4) Tight containers are usually used for Gels. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

11-7. Patches

(1) Patches are preparations intended to be attached on the skin.

Patches are classified into Tapes/Plasters and Cataplasms/Gel Patches.

(2) Patches are usually prepared by mixing active substance(s) homogeneously with a base such as a polymer or a mixture of polymers, spreading on a backing layer or liner, and cutting into a given size. Percutaneous absorption type preparations may be prepared by using a release rate-controlling membrane. Where necessary, adhesive agents or penetration enhancers may be used.

(3) Unless otherwise specified, Patches of Transdermal Systems meet the requirements of Uniformity of Dosage Units.<6.02>.

(4) Patches have a suitable adhesion for application to the skin.

(5) Patches which are regulated the release rate have an appropriate function of controlled release.

11-7-1. Tapes/Plasters

(1) Tapes/Plasters are patches which are prepared with bases of practically no water contain.

Plasters are included in this category.

(2) Tapes/Plasters are usually prepared by mixing homogeneously active substance(s) with or without excipients and a base of non water-soluble natural or synthetic polymers such as resins, plastics or rubber, and spreading on a cloth or spreading and sealing on a cloth or plastic film, cutting into a given size. The preparations may be also prepared by filling a mixture of active substance(s) and a base with or without other excipients in releasers composed with a release-controlling film, supporter and liner.

(3) Well-closed containers are usually used for Tapes/Plasters. For the preparations susceptible to degradation by moisture, a moisture-proof container
or packaging may be used.

11-7-2. Cataplasms/Gel Patches

(1) Cataplasms/Gel Patches are patches using water containing bases.

(2) Cataplasms/Gel patches are usually prepared by mixing active substance(s), Purified Water, and Glycerin or other liquid materials, or by mixing and kneading natural or synthetic polymers, which are soluble in water or absorbent of water, with Purified Water, adding active substance(s), mixing the whole homogeneously, spreading on a cloth or film, and cutting into a given size.

(3) Tight containers are usually used for Cataplasms/Gel Patches. For the preparations susceptible to degradation by evaporation of water, a low-moisture-permeability container or packaging may be used.

[3] Monographs for Preparations Related to Crude Drugs

Preparations Related to Crude Drugs

(1) Preparations related to crude drugs are preparations mainly derived from crude drugs. Extracts, Pills, Spirits, Infusions and Decoctions, Teabags, Tinctures, Aromatic Waters, and Fluidextracts are included in this category.

Definitions, methods of preparations, test methods, containers and packaging, and storage of these preparations are described in this chapter.

(2) The descriptions of the test methods and the containers and packaging in this chapter are fundamental requirements, and the preparation methods represent commonly used methods.

1. Extracts

(1) Extracts are preparations, prepared by concentrating extractives of crude drugs. There are following two kinds of extracts.

(i) Viscous extracts

(ii) Dry extracts

(2) Unless otherwise specified, Extracts are usually prepared as follows.

(i) Crude drugs, pulverized to suitable sizes, are extracted for a certain period of time with suitable solvents by means of cold extraction or warm extraction, or by percolation as directed in (ii) of (2) under 6. Tinctures. The extractive is filtered, and the filtrate is concentrated or dried by a suitable method to make a millet jelly-like consistency for the viscous extracts, or to make crushable solid masses, granules or powder for the dry extracts.

Extracts, which are specified the content of active substance(s), are prepared by assaying active substance(s) in a portion of sample and adjusting, if necessary, to specified strength with suitable diluents.

(ii) Weigh crude drugs, pulverized to suitable sizes, according to the prescription and heat for a certain period of time after adding 10 – 20 times amount of water. After separating the solid and liquid by centrifugation, the extractive is concentrated or dried by a suitable method to make a millet jelly-like consistency for the viscous extracts, or to make crushable solid masses, granules or powder for the dry extracts.

(3) Extracts have order and taste derived from the crude drugs used.

(4) Unless otherwise specified, Extracts meet the requirements of Heavy Metals Limit Test <1.07> when the test solution and the control solution are prepared as follows.

Test solution: Ignite 0.30 g of Extracts to ash, add 3 mL of dilute hydrochloric acid, warm, and filter. Wash the residue with two 5-mL portions of water. Neutralize the combined filtrate and washings (indicator: a drop of phenolphthalein TS) by adding ammonia TS until the color of the solution changes to pale red, filter where necessary, and add 2 mL of dilute acetic acid and water to make 50 mL.

Control solution: Proceed with 3 mL of dilute hydrochloric acid in the same manner as directed in the preparation of the test solution, and add 3.0 mL of Standard Lead Solution and water to make 50 mL.

(5) Tight containers are used for these preparations.

2. Pills

(1) Pills are spherical preparations, intended for oral administration.

(2) Pills are usually prepared by mixing drug substance(s) uniformly with diluents, binders, disintegrators or other suitable excipient(s) and rolling into spherical form by a suitable method. They may be coated with a coating agent by a suitable method.

(3) Unless otherwise specified, Pills comply with Disintegration Test <6.09>.

(4) Well-closed or tight containers are usually used for these preparations.

3. Spirits

(1) Spirits are fluid preparations, usually prepared by dissolving volatile drug substance(s) in ethanol or in a mixture of ethanol and water.

(2) Spirits should be stored remote from fire.

(3) Tight containers are used for these preparations.
4. Infusions and Decoctions

(1) Infusions and Decoctions are fluid preparations, usually obtained by macerating crude drugs in water.

(2) Infusions and Decoctions are usually prepared by the following method.

Cut crude drugs into a size as directed below, and transfer suitable amounts to an infusion or decoction apparatus.

Leaves, flowers and whole plants: Coarse cutting
Woods, stems, barks, roots and rhizomes: Medium cutting
Seeds and fruits: Fine cutting

(i) Infusions: Usually, damp 50 g of crude drugs with 50 mL of water for about 15 minutes, pour 900 mL of hot water to them, and heat for 5 minutes with several stirrings. Filter through a cloth after cooling.

(ii) Decoctions: Usually, heat one-day dose of crude drugs with 400 – 600 mL of water until to lose about a half amount of added water spending more than 30 minutes, and filter through a cloth while warm.

Prepare Infusions or Decoctions when used.

(3) These preparations have odor and taste derived from the crude drugs used.

(4) Tight containers are usually used for these preparations.

5. Teabags

(1) Teabags are preparations, usually packed one-day dose or one dose of crude drugs cut into a size of between coarse powder and coarse cutting in paper or cloth bags.

(2) Teabags are usually used according to the preparation method as directed under 4. Infusions and Decoctions.

(3) Well-closed or tight containers are usually used for these preparations.

6. Tinctures

(1) Tinctures are liquid preparations, usually prepared by extracting crude drugs with ethanol or with a mixture of ethanol and purified water.

(2) Unless otherwise specified, Tinctures are usually prepared from coarse powder or fine cuttings of crude drugs by means of either maceration or percolation as described below.

(i) Maceration: Place crude drugs in a suitable container, and add an amount of a solvent, equivalent to the same volume or about three-fourths of the volume of the crude drugs. Stopper container, and allow the container to stand for about 5 days or until the soluble constituents have satisfactorily dissolved at room temperature with occasional stirring. Separate the solid and liquid by centrifugation or other suitable methods. In the case where about three-fourths volume of the solvent is added, wash the residue with a suitable amount of the solvent, and squeeze the residue, if necessary. Combine the extract and washings, and add sufficient solvent to make up the volume. In the case where the total volume of the solvent is added, sufficient amounts of the solvent may be added to make up for reduced amount, if necessary. Allow the mixture to stand for about 2 days, and obtain a clear liquid by decantation or filtration.

(ii) Percolation: Pour solvent in small portions to crude drugs placed in a container, and mix well to moisten the crude drugs. Stopper container, and allow it to stand for about 2 hours at room temperature. Pack the contents as tightly as possible in an appropriate percolator, open the lower opening, and slowly pour sufficient solvent to cover the crude drugs. When the percolate begins to drip, close the opening, and allow the mixture to stand for 2 to 3 days at room temperature. Then, open the opening, and allow the percolate to drip at a rate of 1 to 3 mL per minute. Add an appropriate quantity of the solvent to the percolator, and continue to percolate until the desired volume has passed. Mix thoroughly, allow standing for 2 days, and obtain a clear liquid by decantation or filtration. The time of standing and the flow rate may be varied depending on the kind and amount of crude drugs to be percolated.

Tinctures, prepared by either of the above methods and specified the content of marker constituent or ethanol, are prepared by assaying the content using a portion of the sample and adjusting the content with a sufficient amount of the percolate or solvent as required on the basis of the result of the assay.

(3) Tinctures should be stored remote from fire.

(4) Tight containers are used for these preparations.

7. Aromatic Waters

(1) Aromatic Waters are clear liquid preparations, saturated essential oils or other volatile substances in water.

(2) Unless otherwise specified, Aromatic Waters are usually prepared by the following process.

Shake thoroughly for 15 minutes 2 mL of an essential oil or 2 g of a volatile substance with 1000 mL of lukewarm purified water, set the mixture aside for 12 hours or longer, filter through moistened filter paper, and add purified water to make 1000 mL. Alterna-
tively, incorporate thoroughly 2 mL of an essential oil or 2 g of a volatile substance with sufficient talc, refined siliceous earth or pulped filter-paper, add 1000 mL of purified water, agitate thoroughly for 10 minutes, and then filter the mixture. To obtain a clear filtrate repeat the filtration if necessary, and add sufficient purified water passed through the filter paper to make 1000 mL.

3) Aromatic Waters have odor and taste derived from the essential oils or volatile substances used.

4) Tight containers are used for these preparations.

8. Fluidextracts

(1) Fluidextracts are liquid percolates of crude drugs, usually prepared so that each mL contains soluble constituents from 1 g of the crude drugs. Where the content is specified, it takes precedence.

(2) Unless otherwise specified, Fluidextracts are usually prepared from coarse powder or fine cutting of crude drugs by either of following maceration or percolation.

(i) Maceration: Place a certain amounts of crude drugs in a suitable vessel, add a solvent to cover the crude drugs, close the vessel, and allow the vessel to stand at room temperature with occasional stirring for about 5 days or until the soluble constituents have satisfactorily dissolved. Separate the solid and liquid by centrifugation or other suitable method. Usually, reserve a volume of the liquid equivalent to about three-fourths of the total volume, and use it as the first liquid. Wash the residue with appropriate amount of the solvent, combine the washings and the remaining of the first liquid, concentrate if necessary, mix with the first liquid, and use it as solution (A). To the solution (A) add the solvent, if necessary, to make equal amount of the mass of the crude drugs. Allow the mixture to stand for about 2 days, and collect a clear liquid by decantation or filtration.

(ii) Percolation: Mix well 1000 g of the crude drugs with the first solvent to moisten them, close the container, and allow it to stand for about 2 hours at room temperature. Transfer the content to a suitable percolator, stuff it as tightly as possible, open the lower opening of the percolator, and slowly pour the second solvent to cover the crude drugs. Close the lower opening when the solvent begins to drop, and allow the mixture to stand for 2 to 3 days at room temperature. Open the lower opening, and allow the percolate to run out at the rate of 0.5 to 1.0 mL per minute.

Set aside the first 850 mL of the percolate as the first percolate. Add the second solvent to the percolator, then drip the percolate, and use it as the second percolate.

The period of standing and the flow rate during percolation may be varied depending on the kind and the amount of crude drugs used. The flow rate is usually regulated as follows, depending on the using amount of crude drugs.

<table>
<thead>
<tr>
<th>Mass of crude drug</th>

<td>2.0 – 4.0 mL</td>
</tr>
</tbody>
</table>

Concentrate the second percolate, taking care not to lose the volatile substances of the crude drug, mix with the first percolate, and use it as solution (A). To the solution (A) add the second solvent to make 1000 mL, and allow the mixture to stand for about 2 days. Decant the supernatant liquid or filter the liquid to obtain a clear solution.

Fluidextracts for which the content of marker constituent or ethanol is specified are obtained by adjusting the content with a sufficient amount of the second solvent as required on the basis of the result of the assay made with a portion of the solution (A).

(3) Fluidextracts have odor and taste derived from the crude drugs used.

(4) Unless otherwise specified, Fluidextracts meet the requirements of Heavy Metals Limit Test <1.07> when the test solution and the control solution are prepared as follows.

Test solution: Ignite 1.0 g of Fluidextracts to ash, add 3 mL of dilute hydrochloric acid, warm, and filter. Wash the residue with two 5-mL portions of water. Neutralize the combined filtrate and washings (indicator: a drop of phenolphthalein TS) by adding ammonia TS until the color of the solution changes to pale red, filter if necessary, and add 2 mL of the dilute acetic acid and water to make 50 mL.

Control solution: Proceed with 3 mL of dilute hydrochloric acid in the same manner as directed in the preparation of the test solution, and add 3.0 mL of Standard Lead Solution and water to make 50 mL.

(5) Tight containers are used for these preparations.
GENERAL TESTS, PROCESSES AND APPARATUS

General Tests, Processes and Apparatus includes common methods for tests, useful test methods for quality recognition of drugs and other articles related to them. Unless otherwise specified, acid-neutralizing capacity determination of gastrointestinal medicines, alcohol number determination, amino acid analysis of proteins, ammonium determination, arsenic determination, atomic absorption spectrophotometry, boiling point determination, chloride determination, conductivity measurement, congealing point determination, determination of bulk and tapped densities, digestion test, disintegration test, dissolution test, distilling range determination, endpoint determination in titrimetry, flame coloration, fluorometry, foreign insoluble matter test for injections, foreign soluble matter test for ophthalmic solutions, gas chromatography, heavy metal determination, infrared spectrophotometry, insoluble particulate matter test for injections, insusolate particulate matter test for ophthalmic solutions, iron determination, liquid chromatography, loss on drying determination, loss on ignition determination, melting point determination, methanol determination, microbial assay for antibiotics, mineral oil determination, nitrogen determination, nuclear magnetic resonance spectroscopy, optical rotation determination, osmolality determination, oxygen flask combustion method, particle size determination, particle size distribution test for preparations, pH determination, powder particle density determination, qualitative test, refractive index determination, residual solvents test, residue on ignition determination, specific gravity and density determination, specific surface area determination, sulfate determination, test for bacterial endotoxins, test for glass containers for injections, test for metal particles in ophthalmic ointments, test for microbial limit, test for microbial limit for crude drugs, test for plastic containers, test for pyrogen, test for readily carbonizable substances, test for rubber closure for aqueous infusions, test for stability, test for total organic carbon, test of extractable volume for injection, thermal analysis, thin-layer chromatography, ultraviolet-visible spectrophotometry, uniformity of dosage units (test for content uniformity, mass variation test), viscosity determination, vitamin A assay, water determination, and X-ray powder diffraction are performed as directed in the corresponding articles under the General Tests, Processes and Apparatus. The tests for melting point of fats, congealing point of fatty acids, specific gravity, acidity, saponification value, ester value, hydroxyl value, unsaponifiable matter and iodine value of fats and fatty oils are performed as directed in the corresponding items under Fats and Fatty Oils Test, and sampling, preparation of sample for analysis, microscopic examination, purity test, loss on drying, total ash, acid-insoluble ash, extract content, and essential oil content of crude drugs are performed as directed in the corresponding items under Crude Drugs Test.

The number of each test method is a category number given individually. The number in brackets (<>) appeared in monograph indicates the number corresponding to the general test method.

1. Chemical Methods

1.01 Alcohol Number Determination

Alcohol Number Determination represents the number of milliliters of ethanol at 15°C obtained from 10 mL of tincture or other preparations containing ethanol by the following procedures.

1. Method 1 Distilling method

This is a method to determine the Alcohol Number by reading the number of milliliters of ethanol distillate at 15°C obtained from 10 mL of a sample measured at 15°C by the following procedures.

1.1. Apparatus

Use hard glass apparatus as illustrated in Fig. 1.01-1. Ground glass may be used for the joints.

1.2. Reagent

Alkaline phenolphthalein solution: To 1 g of phenolphthalein add 7 mL of sodium hydroxide TS and water to make 100 mL.

1.3. Procedure

Transfer 10 mL of the sample preparation, accurately measured at 15 ± 2°C, to the distilling flask A, add 5 mL of water and boiling chips. Distil ethanol carefully into the glass-stoppered, volumetric cylinder D.

By reference to Table 1.01-1, a suitable volume of distillate (mL) should be collected, according to the content of ethanol in the sample preparation.

Prevent bumping during distillation by rendering the sample strongly acidic with phosphoric acid or sulfuric acid, or by adding a small amount of paraffin, beeswax or silicone resin before starting the distillation.

Table 1.01-1

When the samples contain the following substances, carry out pretreatment as follows before distillation.

(i) Glycerin: Add sufficient water to the sample so that the residue in the distilling flask, after distillation, contains at least 50% of water.

(ii) Iodine: Decolorize the sample with zinc powder.

(iii) Volatile substances: Preparations containing appreciable proportions of essential oil, chloroform, diethyl ether or camphor require treatment as follows. Mix 10 mL of the sample, accurately measured, with 10 mL of saturated sodium chloride solution in a separator, add 10 mL of petroleum benzin, and shake. Collect the separated aqueous layer. The petroleum benzin layer was extracted with two 5 mL portions of saturated sodium chloride solution. Combine the aqueous layers, and distill. According to the ethanol content in the sample, collect a volume of distillate 2 to 3 mL more than that shown in the above Table.

(iv) Other substances: Render preparations containing free ammonia slightly acidic with dilute sulfuric acid. If volatile acids are present, render the preparation slightly alkaline with sodium hydroxide TS, and if the preparations contain soap along with volatile substances, decompose the soap with an excess of dilute sulfuric acid before the extraction with petroleum benzin in the treatment described in (iii).

To the distillate add 4 to 6 g of potassium carbonate and 1 to 2 drops of alkaline phenolphthalein solution, and shake vigorously. If the aqueous layer shows no white turbidity, agitate the distillate with additional potassium carbonate. After allowing to stand in water at 15 ± 2°C for 30 minutes, read the volume of the upper reddish ethanol layer in mL, and regard it as the Alcohol Number. If there is no clear boundary surface between these two layers, shake vigorously after addition of a few drops of water, then observe in the same manner.

2. Method 2 Gas chromatography

This is a method to determine the alcohol number by determining ethanol (C₂H₅OH) content (vol%) from a sample measured at 15°C by the following procedures.

2.1. Reagent

Ethanol for alcohol number: Ethanol (99.5) with determined ethanol (C₂H₅OH) content. The relation between specific gravity \( d_{15}^{15} \) of ethanol and content of ethanol (C₂H₅OH) is 0.797:99.46 vol%, 0.796:99.66 vol%, and 0.795:99.86 vol%.

2.2. Preparation of sample solution and standard solution

Sample solution: Measure accurately a volume of sample at 15 ± 2°C equivalent to about 5 mL of ethanol (C₂H₅OH), and add water to make exactly 50 mL. Measure accurately 25 mL of this solution, add exactly 10 mL of the internal standard solution, and add water to make 100 mL.

Standard solution: Measure accurately 5 mL of ethanol for alcohol number at the same temperature as the sample, and add water to make exactly 50 mL. Measure accurately 25 mL of this solution, add exactly 10 mL of the internal standard solution, and add water to make 100 mL.

2.3. Procedure

Place 25 mL each of the sample solution and the standard solution in a 100-mL, narrow-mouthed, cylindrical glass bottle sealed tightly with a rubber closure and aluminum band, immerse the bottle up to the neck in water, allowed to stand at room temperature for more than 1 hour in a room with little change in temperature, shake gently so as not to splash the solution on the closure, and allow to stand for 30 minutes. Perform the test with 1 mL each of the gas in the bottle with a syringe according to the Gas Chromatography <2.02> under the following conditions, and calculate the ratios, \( Q_T \) and \( Q_S \), of the peak height of ethanol to that of the internal standard.

\[
\text{Alcohol number} = \frac{Q_T}{Q_S} \times \frac{5 \text{ (mL)}}{\text{a volume (mL) of sample}} \times \frac{\text{ethanol (C}_2\text{H}_5\text{OH) content (vol\%) of ethanol for alcohol number}}{9.406}
\]

*Internal standard solution*—A solution of acetonitrile (3 in 50).

*Operating conditions*—

Detector: A hydrogen flame-ionization detector.

Column: A glass tube about 3 mm in inside diameter and about 1.5 m in length, packed with 150- to 180-μm porous ethylvinylbenzene-divinylbenzene copolymer (mean pore
1.02 Ammonium Limit Test

Ammonium Limit Test is a limit test for ammonium contained in drugs.

In each monograph, the permissible limit for ammonium (as NH$_4^+$) is described in terms of percentage (%) in parentheses.

1. Apparatus

Use a distilling apparatus for ammonium limit test as illustrated in Fig. 1.02-1. For the distillation under reduced pressure, use the apparatus shown in Fig. 1.02-2. Either apparatus are composed of hard glass, and ground-glass joints may be used. All rubber parts used in the apparatus should be boiled for 10 to 30 minutes in sodium hydroxide TS and for 30 to 60 minutes in water, and finally washed thoroughly with water before use.

2. Procedure

2.1. Preparation of test solution and control solution

Unless otherwise specified, test solutions and control solution are prepared as directed in the following.

Place an amount of the sample, directed in the monograph, in the distilling flask A. Add 140 mL of water and 2 g of magnesium oxide, and connect the distillation apparatus. To the receiver (measuring cylinder) F add 20 mL of boric acid solution (1 in 200) as an absorbing solution, and immerse the lower end of the condenser. Adjust the heating to give a rate of 5 to 7 mL per minute of distillate, and distill until the distillate measures 60 mL. Remove the receiver from the lower end of the condenser, rinsing the end part with a small quantity of water, add sufficient water to make 100 mL and designate it as the test solution.

For the distillation under reduced pressure, take the amount of sample specified in the monograph to the vacuum distillation flask L, add 70 mL of water and 1 g of magnesium oxide, and connect to the apparatus (Fig. 1.02-2). To the receiver M add 20 mL of a solution of boric acid (1 in 200) as absorbing liquid, put the end of the branch tube of the distillation flask L in the absorbing liquid, and keep at 60°C using a water bath or alternative equipment. Adjust the reduced pressure to get the distillate at a rate of 1 to 2 mL per minute, and continue the distillation until to get 30 mL of the distillate. Cool the receiver M with running water during the distillation. Get off the end of the branch tube from surface of the absorbing liquid, rinse in the end with a small amount of water, then add water to the liquid to make 100 mL, and perform the test using this solution as the test solution.

Place a volume of Standard Ammonium Solution, directed in the monograph, in the distilling flask A or the vacuum distillation flask L, proceed as for the preparation.
1.03 Chloride Limit Test

Chloride Limit Test is a limit test for chloride contained in drugs.

In each monograph, the permissible limit for chloride (as Cl) is described in terms of percentage (%) in parentheses.

1. Procedure

Unless otherwise specified, transfer the quantity of the sample, directed in the monograph, to a Nessler tube, and dissolve it in a proper volume of water to make 40 mL. Add 6 mL of dilute nitric acid and water to make 50 mL, and use this solution as the test solution. Transfer the volume of 0.01 mol/L hydrochloric acid VS, directed in the monograph, to another Nessler tube, add 6 mL of dilute nitric acid and water to make 50 mL, and use this solution as the control solution.

When the test solution is not clear, filter both solutions by using the same procedure.

Add 1 mL of silver nitrate TS to the test solution and to the control solution, mix well, and allow to stand for 5 minutes protecting from light. Compare the opalescence developed in both solutions against a white background by viewing downward or transversely: the color developed in the test solution is not more intense than that of the control solution.

1.04 Flame Coloration Test

Flame Coloration Test is a method to detect an element, by means of the property that the element changes the colorless flame of a Bunsen burner to its characteristic color.

(1) Salt of metal—The platinum wire used for this test is about 0.8 mm in diameter, and the end part of it is straight. In the case of a solid sample, make the sample into a gruel by adding a small quantity of hydrochloric acid, apply a little of the gruel to the 5-mm end of the platinum wire, and test by putting the end part in a colorless flame, keeping the platinum wire horizontal. In the case of a liquid sample, immerse the end of the platinum wire into the sample to about 5 mm in length, remove from the sample gently, and perform the test in the same manner as for the solid sample.

(2) Halide—Cut a copper net, 0.25 mm in opening and 0.174 mm in wire diameter, into a strip 1.5 cm in width and 5 cm in length, and wind in round one end of a copper wire. Heat the copper net strongly in the colorless flame of Bunsen burner until the flame no longer shows a green or blue color, and then cool it. Repeat this procedure several times, and coat the net completely with cupric oxide. After cooling, unless otherwise specified, apply about 1 mg of the sample to the copper net, ignite, and burn it. Repeat this procedure three times, and then test by putting the copper net in the colorless flame.

The description, “Flame coloration persists”, in a monograph, indicates that the reaction persists for 4 seconds.

1.05 Mineral Oil Test

Mineral Oil Test is a method to test mineral oil in nonaqueous solvents for injections and for eye drops.

1. Procedure

Pour 10 mL of the sample into a 100-mL flask, and add 15 mL of sodium hydroxide solution (1 in 6) and 30 mL of ethanol (95). Put a short-stemmed, small funnel on the neck of the flask, and heat on a water bath to make clear, with frequent shaking. Then transfer the solution to a shallow porcelain dish, evaporate the ethanol on a water bath, add 100 mL of water to the residue, and heat on a water bath: no turbidity is produced in the solution.

1.06 Oxygen Flask Combustion Method

Oxygen Flask Combustion Method is a method for the identification or the determination of halogens or sulfur produced by combusting organic compounds, which contain chlorine, bromine, iodine, fluorine or sulfur, in a flask filled with oxygen.

1. Apparatus

Use the apparatus shown in Fig. 1.06-1.

2. Preparation of test solution and blank solution

Unless otherwise specified, prepare them by the following method.

2.1. Preparation of sample

(i) For solid samples: Place the quantity of the sample specified in the monograph on the center of the filter illustrated in the figure, weigh accurately, wrap the sample carefully along the dotted line without scattering, and place the parcel in a platinum basket or cylinder B, leaving its fusetrip on the outside.

(ii) For liquid samples: Roll a suitable amount of absorbent cotton with filter paper, 50 mm in length and 5 mm in width, so that the end part of the paper is left to a length of about 20 mm as a fuse-strip, and place the parcel in a platinum basket or cylinder B. Place the sample in a suitable glass tube, weigh accurately, and moisten the cotton with the quantity of the sample specified in the monograph, bringing the edge of the sample in contact with the cotton.

2.2. Method of combustion

Place the absorbing liquid specified in the monograph in flask A, fill it with oxygen, moisten the ground part of the stopper C with water, then ignite the fuse-strip, immediately transfer it to the flask, and keep the flask airtight until the combustion is completed. Shake the flask occasionally until
3. Procedure of determination

3.1. Chlorine and bromine

Apply a small amount of water to the upper part of A, pull out C carefully, and transfer the test solution to a beaker. Wash C, B and the inner side of A with 15 mL of 2-propanol, and combine the washings with the test solution. To this solution add 1 drop of bromophenol blue TS, then add dilute nitric acid dropwise until a yellow color develops, and titrate \(<2.50\) with 0.005 mol/L silver nitrate VS according to the potentiometric titration. Perform the test with the blank solution in the same manner, and make any necessary correction.

Each mL of 0.005 mol/L silver nitrate VS = 0.6345 mg of Cl

Each mL of 0.005 mol/L silver nitrate VS = 0.3995 mg of Br

3.2. Iodine

Apply a small amount of water to the upper part of A, pull out C carefully, add 2 drops of hydrazine hydrate to the test solution, put C on A, and decolorize the solution by vigorous shaking. Transfer the content of A to a beaker, wash C, B and the inner side of A with 25 mL of 2-propanol, and transfer the washings to the above beaker. To this solution add 1 drop of bromophenol blue TS, then add dilute nitric acid dropwise until a yellow color develops, and titrate \(<2.50\) with 0.005 mol/L silver nitrate VS according to the potentiometric titration. Perform the test with the blank solution in the same manner, and make any necessary correction.

Each mL of 0.005 mol/L silver nitrate VS

3.3. Fluorine

Apply a small amount of water to the upper part of A, pull out C carefully, transfer the test solution and the blank solution to 50 mL volumetric flasks separately, wash C, B and the inner side of A with water, add the washings and water to make 50 mL, and use these solutions as the test solution and the correction solution. Pipet the test solution \((V\ mL)\) equivalent to about 30 \(\mu\)g of fluorine, add 25 mL of a mixture of alizarin complexone TS, acetic acid-potassium acetate buffer solution, pH 4.3 and cerium (III) nitrate TS (1:1:1), add water to make 50 mL, and allow to stand for 1 hour. Perform the test with these solutions as directed under Ultraviolet-visible Spectrophotometry \(<2.24\>, using a blank prepared with 5 mL of water in the same manner. Determine the absorbances, \(A_T\), \(A_C\) and \(A_S\) of the subsequent solutions of the test solution, the correction solution and the standard solution at 600 nm.

\[
\text{Amount (mg) of fluorine (F) in the test solution} = \frac{\text{amount (mg) of fluorine in 5 mL of the standard solution} \times (A_T - A_C) \times 50}{V}
\]

Standard Fluorine Solution: Dry sodium fluoride (standard reagent) in a platinum crucible between 500°C and 550°C for 1 hour, cool it in a desiccator (silica gel), weigh accurately about 66.3 mg of it, and dissolve in water to make exactly 500 mL. Pipet 10 mL of this solution, and dilute with sufficient water to make exactly 100 mL.

3.4. Sulfur

Apply a small amount of water to the upper part of A, pull out C carefully, and wash C, B and the inner side of A with 15 mL of methanol. To this solution add 40 mL of methanol, then add exactly 25 mL of 0.005 mol/L barium perchlorate VS, allow to stand for 10 minutes, add 0.15 mL of arsenazo III TS with a measuring pipet, and titrate \(<2.50\) with 0.005 mol/L sulfuric acid VS. Perform the test with the blank solution in the same manner.

Each mL of 0.005 mol/L barium perchlorate VS

1.07 Heavy Metals Limit Test

Heavy Metals Limit Test is a limit test of the quantity of heavy metals contained as impurities in drugs. The heavy metals are the metallic inclusions that are darkened with so-
dium sulfide TS in acidic solution, as their quantity is expressed in terms of the quantity of lead (Pb).

In each monograph, the permissible limit for heavy metals (as Pb) is described in terms of ppm in parentheses.

1. Preparation of test solutions and control solutions

Unless otherwise specified, test solutions and control solutions are prepared as directed in the following:

1.1. Method 1

Place an amount of the sample, directed in the monograph, in a Nessler tube. Dissolve in water to make 40 mL. Add 2 mL of dilute acetic acid and water to make 50 mL, and designate it as the test solution.

The control solution is prepared by placing the volume of Standard Lead Solution directed in the monograph in a Nessler tube, and adding 2 mL of dilute acetic acid and water to make 50 mL.

1.2. Method 2

Place an amount of the sample, directed in the monograph, in a quartz or porcelain crucible, cover loosely with a lid, and carbonize by gentle ignition. After cooling, add 2 mL of nitric acid and 5 drops of sulfuric acid, heat cautiously until white fumes are no longer evolved, and incinerate by ignition between 500°C and 600°C. Cool, add 2 mL of hydrochloric acid, evaporate to dryness on a water bath, moisten the residue with 3 drops of hydrochloric acid, add 10 mL of hot water, and warm for 2 minutes. Then add 1 drop of phenolphthalein TS, add ammonia TS dropwise until the solution develops a pale red color, add 2 mL of dilute acetic acid, filter if necessary, and wash with 10 mL of water. Transfer the filtrate and washings to a Nessler tube, and add water to make 50 mL. Designate it as the test solution.

The control solution is prepared as follows: Evaporate a mixture of 2 mL of nitric acid, 5 drops of sulfuric acid and 2 mL of hydrochloric acid on a water bath, further evaporate to dryness on a sand bath, and moisten the residue with 3 drops of hydrochloric acid. Hereinafter, proceed as directed in the test solution, then add the volume of Standard Lead Solution directed in the monograph and water to make 50 mL.

1.3. Method 3

Place an amount of the sample, directed in the monograph, in a platinum or porcelain crucible, mix with 10 mL of a solution of magnesium nitrate hexahydrate in ethanol (95) (1 in 10), fire the ethanol to burn, and carbonize by gradual heating. Cool, add 1 mL of sulfuric acid, heat carefully, and incinerate by ignition between 500°C and 600°C. If a carbonized substance remains, moisten with a small amount of sulfuric acid, and incinerate by ignition. Cool, dissolve the residue in 3 mL of hydrochloric acid, evaporate on a water bath to dryness, wet the residue with 3 drops of hydrochloric acid, add 10 mL of water, and dissolve by warming. Add 1 drop of phenolphthalein TS, add ammonia TS dropwise until a pale red color develops, then add 2 mL of dilute acetic acid, filter if necessary, wash with 10 mL of water, transfer the filtrate and the washing to a Nessler tube, add water to make 50 mL, and use this solution as the test solution.

The control solution is prepared as follows: Take 10 mL of a solution of magnesium nitrate hexahydrate in ethanol (95) (1 in 10), and fire the ethanol to burn. Cool, add 1 mL of sulfuric acid, heat carefully, and ignite between 500°C and 600°C. Cool, and add 3 mL of hydrochloric acid. Hereinafter, proceed as directed in the test solution, then add the volume of Standard Lead Solution directed in the monograph and water to make 50 mL.

2. Procedure

Add 1 drop of sodium sulfide TS to each of the test solution and the control solution, mix thoroughly, and allow to stand for 5 minutes. Then compare the colors of both solutions by viewing the tubes downward or transversely against a white background. The test solution has no more color than the control solution.

1.08 Nitrogen Determination (Semimicro-Kjeldahl Method)

Nitrogen Determination is a method to determine nitrogen in an organic substance in which the nitrogen is converted into ammonia nitrogen by thermal decomposition of the organic substance with sulfuric acid, and the ammonia liberated by alkali and trapped by distillation with steam is determined by titration.

1. Apparatus

Use the apparatus illustrated in Fig. 1.08-1. It is thoroughly constructed of hard glass, and ground glass surfaces may be used for joints. All rubber parts used in the apparatus should be boiled for 10 to 30 minutes in sodium hydroxide TS and for 30 to 60 minutes in water, and finally washed thoroughly with water before use.

Alternatively, apparatus can be used in which some of the procedures, such as digestion of organic substances, distillation of the liberated ammonia, and endpoint detection methods in titrimetry (e.g., potentiometric titration or titration by colorimeter) are automated.

2. System suitability

If an automated apparatus is used, it is necessary to confirm periodically the suitability of the apparatus according to the following method:

Weigh accurately about 1.7 g of amidosulfuric acid (standard reagent), previously dried in a desicator (in vacuum, silica gel) for about 48 hours, dissolve in water to make exactly 200 mL. Pipet 2 mL of this solution, and transfer to a
digestion flask. When the test is performed as directed in the
instrumental manual the nitrogen content (%) in amidosulfuric acid should be determined between 14.2% and 14.6%.

3. Reagents, Test Solutions
Decomposition accelerator: Unless otherwise specified, use 1 g of a powdered mixture of 10 g of potassium sulfate and 1 g of copper (II) sulfate pentahydrate. The composition and amount of the digestion accelerator may be modified if it is confirmed that the modified one give almost the same results using the sample as those obtained from the conventional catalyst.

4. Procedure
Unless otherwise specified, proceed by the following method. Weigh accurately or pipet a quantity of the sample corresponding to 2 to 3 mg of nitrogen (N:14.01), and place in the Kjeldahl flask A. Add the decomposition accelerator and wash down any adhering sample from the neck of the flask with a small quantity of water. Add 7 mL of sulfuric acid, allowing it to flow down the inside wall of the flask.

Then, while shaking the flask, add cautiously 1 mL of hydrogen peroxide (30) drop by drop along the inside wall of the flask. Heat the flask gradually, then heat so strong that

the vapor of sulfuric acid is condensed at the neck of the flask, until the solution changes through a blue and clear to a vivid green and clear, and the inside wall of the flask is free from a carbonaceous material. If necessary, add a small quantity of hydrogen peroxide (30) after cooling, and heat again. After cooling, add cautiously 20 mL of water, cool the solution, and connect the flask to the distillation apparatus (Fig. 1.08.1) washed beforehand by passing stream through it. To the absorption flask K add 15 mL of boric acid solution (1 in 25), 3 drops of bromocresol green-methyl red TS and sufficient water to immerse the lower end of the condenser tube J. Add 30 mL of sodium hydroxide solution (2 in 5) through the funnel F, rinse cautiously the funnel with 10 mL of water, lose the clamp attached to the rubber tubing G, then begin the distillation with stream, and continue until the distillate measures 80 to 100 mL. Remove the absorption flask from the lower end of the condenser tube J, rinsing the end part with a small quantity of water, and titrate with 0.005 mol/L sulfuric acid VS until the color of the solution changes from green through pale grayish blue to pale grayish red-purple. Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.005 mol/L sulfuric acid VS

= 0.1401 mg of N

If an automated apparatus is used, proceed as directed in the instrumental procedure.

1.09 Qualitative Tests

Qualitative Tests are applied to the identification of drugs and are done generally with quantities of 2 to 5 mL of the test solution.

Acetate
(1) When warmed with diluted sulfuric acid (1 in 2), acetates evolve the odor of acetic acid.
(2) When an acetate is warmed with sulfuric acid and a small quantity of ethanol (95), the odor of ethyl acetate is evolved.
(3) Neutral solutions of acetates produce a red-brown color with iron (III) chloride TS, and a red-brown precipitate when boiled. The precipitate dissolves and the color of the solution changes to yellow upon addition of hydrochloric acid.

Aluminum salt
(1) Solutions of aluminum salts, when treated with ammonium chloride TS and ammonia TS, yield a gelatinous, white precipitate which does not dissolve in an excess of ammonia TS.
(2) Solutions of aluminum salts, when treated with sodium hydroxide TS, yield a gelatinous, white precipitate which dissolves in an excess of the reagent.
(3) Solutions of aluminum salts, when treated with sodium sulfide TS, yield a gelatinous, white precipitate which dissolves in an excess of the reagent.
(4) Add ammonia TS to solutions of aluminum salts until a gelatinous, white precipitate is produced. The color of the precipitate changes to red upon addition of 5 drops of alizarin red S TS.
Ammonium salt
When heated with an excess of sodium hydroxide TS, ammonium salts evolve the odor of ammonia. This gas changes moistened red litmus paper to blue.

Antimony salt, primary
1. When primary antimony salts are dissolved in a slight excess of hydrochloric acid for the test and then diluted with water, a white turbidity is produced. The mixture produces an orange precipitate upon addition of 1 to 2 drops of sodium sulfide TS. When the precipitate is separated, and sodium sulfide TS is added to one portion of the precipitate and sodium hydroxide TS is added to another portion, it dissolves in either of these reagents.
2. Add water to acidic solutions of primary antimony salts in hydrochloric acid until a small quantity of precipitate is produced, and then add sodium thiosulfate TS: the precipitate dissolves. A red precipitate is reproduced when the solution is heated.

Aromatic amines, primary
Acidic solutions of primary aromatic amines, when cooled in ice, mixed with 3 drops of sodium nitrite TS under agitation, allowed to stand for 2 minutes, mixed well with 1 mL of ammonium amidosulfate TS, allowed to stand for 1 minute, and then mixed with 1 mL of N,N-diethyl-N'-1-naphthylethylenediamine oxalate TS, exhibit a red-purple color.

Arsenate
1. Neutral solutions of arsenates produce no precipitate with 1 to 2 drops of sodium sulfide TS, but produce a yellow precipitate with hydrochloric acid subsequently added. The separated precipitate dissolves in ammonium carbonate TS.
2. Neutral solutions of arsenates produce a dark red-brown precipitate with silver nitrate TS. When dilute nitric acid is added to one portion of the suspension, and ammonium TS is added to another portion, the precipitate dissolves in either of these reagents.
3. Neutral or ammonia alkaline solutions of arsenates produce with magnesia TS a white, crystalline precipitate, which dissolves by addition of dilute hydrochloric acid.

Arsenite
1. Acidic solutions of arsenites in hydrochloric acid produce a yellow precipitate with 1 to 2 drops of sodium sulfide TS. When hydrochloric acid is added to one portion of the separated precipitate, it does not dissolve. When ammonium carbonate TS is added to another portion, the precipitate dissolves.
2. Slightly alkaline solutions of arsenites produce a yellowish white precipitate with silver nitrate TS. When ammonium TS is added to one portion of the suspension, and dilute nitric acid is added to another portion, the precipitate dissolves in either of these reagents.
3. Slightly alkaline solutions of arsenites produce a green precipitate with copper (II) sulfate TS. When the separated precipitate is boiled with sodium hydroxide TS, it changes to red-brown.

Barium salt
1. When the Flame Coloration Test (1) C1.04 is applied to barium salts, a persistent yellow-green color develops.
2. Solutions of barium salts produce with dilute sulfuric acid a white precipitate, which does not dissolve upon addition of dilute nitric acid.
3. Acidic solutions of barium salts in acetic acid produce a yellow precipitate with potassium chromate TS. The precipitate dissolves by addition of dilute nitric acid.

Bicarbonate
1. Bicarbonates effervesce upon addition of dilute hydrochloric acid, generating a gas, which produces a white precipitate immediately, when passed into calcium hydroxide TS (common with carbonates).
2. Solutions of bicarbonates produce no precipitate with magnesium sulfate TS, but produce a white precipitate when boiled subsequently.
3. A cold solution of bicarbonates remains unchanged or exhibits only a slightly red color upon addition of 1 drop of phenolphthalein TS (discrimination from carbonates).

Bismuth salt
1. Bismuth salts, dissolved in a slight excess of hydrochloric acid, yield a white turbidity upon dilution with water. A dark brown precipitate is produced with 1 to 2 drops of sodium sulfide TS subsequently added.
2. Acidic solutions of bismuth salts in hydrochloric acid exhibit a yellow color upon addition of thiourea TS.
3. Solution of bismuth salts in dilute nitric acid or in dilute sulfuric acid yield with potassium iodide TS a black precipitate, which dissolves in an excess of the reagent to give an orange-colored solution.

Borate
1. When ignite a mixture of a borate with sulfuric acid and methanol, it burns with a green flame.
2. Turmeric paper, when moistened with acidic solutions of borates in hydrochloric acid and dried by warming, exhibits a red color, which changes to blue with ammonia TS added dropwise.

Bromate
1. Acidic solutions of bromates in nitric acid yield with 2 to 3 drops of silver nitrate TS a white, crystalline precipitate, which dissolves upon heating. When 1 drop of sodium nitrite TS is added to this solution, a pale yellow precipitate is produced.
2. Acidic solutions of bromates in nitric acid exhibit a yellow to red-brown color upon addition of 5 to 6 drops of sodium nitrite TS. When 1 mL of chloroform is added to the mixture and shaken, the chloroform layer exhibits a yellow to red-brown color.

Bromide
1. Solutions of bromides yield a pale yellow precipitate with silver nitrate TS. Upon addition of dilute nitric acid to a portion of the separated precipitate, it does not dissolve. When ammonia solution (28) is added to another portion and shaken, the separated solution yields a white turbidity upon acidifying with dilute nitric acid.
(2) Solutions of bromides exhibit a yellow-brown color with chlorine TS. The mixture is separated into 2 portions. When one portion is shaken with chloroform, the chloroform layer exhibits a yellow-brown to red-brown color. When phenol is added to the other portion, a white precipitate is produced.

**Calcium salt**

(1) When the Flame Coloration Test (1) is applied to calcium salts, a yellow-red color develops.
(2) Solutions of calcium salts yield a white precipitate with ammonium carbonate TS.
(3) Solutions of calcium salts yield a white precipitate with ammonium oxalate TS. The separated precipitate does not dissolve in dilute acetic acid, but dissolves in dilute hydrochloric acid.
(4) Neutral solutions of calcium salts produce no precipitate, when mixed with 10 drops of potassium chromate TS and heated (discrimination from strontium salts).

**Carbonate**

(1) Carbonates effervesce upon addition of dilute hydrochloric acid, generating a gas, which produces a white precipitate immediately, when passed into calcium hydroxide TS (common with biconarbonates).
(2) Solutions of carbonates yield with magnesium sulfate TS a white precipitate, which dissolves by addition of dilute acetic acid.
(3) Cold solutions of carbonates exhibit a red color with 1 drop of phenolphthalein TS (discrimination from bicarbonates).

**Ceric salt**

(1) When a cerous salt is mixed with 2.5 times its mass of lead (IV) oxide, nitric acid is added and the solution is boiled, it exhibits a yellow color.
(2) Solutions of cerous salts yield a yellow to red-brown precipitate upon addition of hydrogen peroxide TS and ammonia TS.

**Chlorate**

(1) Solutions of chlorates yield no precipitate with silver nitrate TS. When 2 to 3 drops of sodium nitrite TS and dilute nitric acid are added to the mixture, a white precipitate is produced gradually, which dissolves by addition of ammonia TS.
(2) When indigocarmine TS is added dropwise to neutral solutions of chlorates until a pale blue color appears, and the mixture is acidified with dilute sulfuric acid, the blue color vanishes promptly upon subsequent dropwise addition of sodium hydrosulfite TS.

**Chloride**

(1) Solution of chlorides evolve an odor of chlorine, when mixed with sulfuric acid and potassium permanganate, and heated. The gas evolved turns moistened potassium iodide starch paper blue.
(2) Solutions of chlorides yield a white precipitate with silver nitrate TS. When dilute nitric acid is added to a portion of the separated precipitate, it does not dissolve. When an excess of ammonia TS is added to another portion, the precipitate dissolves.

**Chromate**

(1) Solutions of chromates exhibit a yellow color.
(2) Solutions of chromates produce a yellow precipitate with lead (II) acetate TS. When acetic acid (31) is added to a portion of the suspension, the precipitate does not dissolve. When dilute nitric acid is added to another portion, the precipitate dissolves.
(3) When acidic solutions of chromates in sulfuric acid are mixed with an equal volume of ethyl acetate and 1 to 2 drops of hydrogen peroxide TS, shaken immediately and allowed to stand, the ethyl acetate layer exhibits a blue color.

**Citrate**

(1) When 20 mL of a mixture of pyridine and acetic anhydride (3:1) is added to 1 or 2 drops of a solution of citrate, and the solution is allowed to stand for 2 to 3 minutes, a red-brown color develops.
(2) Neutral solutions of citrates, when mixed with an equal volume of dilute sulfuric acid and two-thirds volume of potassium permanganate TS, heated until the color of permanganate is discharged, and then treated dropwise with bromine TS to one-tenth of total volume, yield a white precipitate.
(3) Neutral solutions of citrates, when boiled with an excess of calcium chloride TS, yield a white crystalline precipitate. When sodium hydroxide TS is added to a portion of the separated precipitate, it does not dissolve. When dilute hydrochloric acid is added to another portion, the precipitate dissolves.

**Cupric salt**

(1) When a well polished iron plate is immersed in acidic solutions of cupric salts in hydrochloric acid, a red metallic film appears on its surface.
(2) Solutions of cupric salts produce a pale blue precipitate with a small quantity of ammonia TS. The precipitate dissolves in an excess of the reagent, yielding a deep blue-colored solution.
(3) Solutions of cupric salts yield a red-brown precipitate with potassium hexacyanoferrate (II) TS. When dilute nitric acid is added to a portion of the suspension, the precipitate does not dissolve. When ammonia TS is added to another portion, the precipitate dissolves, yielding a deep blue-colored solution.
(4) Solutions of cupric salts produce a black precipitate with sodium sulfide TS. When dilute hydrochloric acid, dilute sulfuric acid or sodium hydroxide TS is added to a portion of the separated precipitate, it does not dissolve. When hot dilute nitric acid is added to another portion, the precipitate dissolves.

**Cyanide**

(1) Solutions of cyanides yield a white precipitate with an excess of silver nitrate TS. When dilute nitric acid is added to a portion of the separated precipitate, it does not dissolve. When ammonia TS is added to another portion, the precipitate dissolves.
(2) Solutions of cyanides yield a blue precipitate, when mixed by shaking with 2 to 3 drops of iron (II) sulfate TS, 2 to 3 drops of dilute iron (III) chloride TS and 1 mL of sodium hydroxide TS, and then acidified with dilute sulfuric acid.

**Dichromate**

(1) Solutions of dichromates exhibit a yellow-red color.
(2) Solutions of dichromates produce a yellow precipitate with lead (II) acetate TS. When acetic acid (31) is added to one portion of the suspension, the precipitate does not
Ferricyanide

(1) Slightly acidic solutions of ferric salts yield with potassium hexacyanoferrate (II) TS a blue precipitate, which does not dissolve in dilute hydrochloric acid subsequently added.

(2) Solutions of ferric salts yield with sodium hydroxide TS a gelatinous, red-brown precipitate, which changes to black upon addition of sodium sulfide TS. The separated precipitate dissolves in dilute hydrochloric acid, yielding a white turbidity.

(3) Slightly acidic solutions of ferric salts exhibit a purple color with 5-sulfosalicylic acid TS.

Ferricyanide

(1) Solutions of ferricyanides exhibit a yellow color.

(2) Solutions of ferricyanides yield with iron (II) sulfate TS a blue precipitate, which does not dissolve in dilute hydrochloric acid subsequently added.

Ferrocyanide

(1) Solutions of ferrocyanides yield with iron (III) chloride TS a blue precipitate, which does not dissolve in dilute hydrochloric acid subsequently added.

(2) Solutions of ferrocyanides yield with copper (II) sulfate TS a red-brown precipitate, which does not dissolve in dilute hydrochloric acid subsequently added.

Ferrous salt

(1) Slightly acidic solutions of ferrous salts yield with potassium hexacyanoferrate (III) TS a blue precipitate, which does not dissolve in dilute hydrochloric acid subsequently added.

(2) Solutions of ferrous salts yield with sodium hydroxide TS a greenish gray, gelatinous precipitate, which changes to black with sodium sulfide TS. The separated precipitate dissolves in dilute hydrochloric acid.

(3) Neutral or slightly acidic solutions of ferrous salts exhibit an intense red color upon dropwise addition of a solution of 1,10-phenanthroline monohydrate in ethanol (95) (1 in 50).

Fluoride

(1) When solutions of fluorides are heated with chromic acid-sulfuric acid TS, the inside of the test tube is not moistened uniformly.

(2) Neutral or slightly acidic solutions of fluorides exhibit a blue-purple color after standing with 1.5 mL of a mixture of alizarin complexone TS, acetic acid-potassium acetate buffer solution, pH 4.3, and cerium (III) nitrate TS (1:1:1).

Glycerophosphate

(1) Solutions of glycerophosphates remain unaffected by addition of calcium chloride TS, but yield a precipitate when boiled.

(2) Solutions of glycerophosphates yield no precipitate with hexaammonium heptamolybdate TS in the cold, but yield a yellow precipitate when boiled for a long time.

(3) When glycerophosphates are mixed with an equal mass of powdered potassium hydrogen sulfate and heated gently over a free flame, the pungent odor of acrolein is evolved.

Iodide

(1) Solutions of iodides yield a yellow precipitate with silver nitrate TS. When dilute nitric acid is added to one portion of the suspension, and ammonia solution (28) to another portion, the precipitates do not dissolve in either of these reagents.

(2) Acidic solutions of iodides exhibit a yellow-brown color with 1 to 2 drops of sodium nitrite TS and then yield a black-purple precipitate. The solutions exhibit a deep blue color with starch TS subsequently added.

Lactate

Acidic solutions of lactates in sulfuric acid, when heated with potassium permanganate TS, evolve the odor of acetaldehyde.

Lead salt

(1) Solutions of lead salts yield a white precipitate with dilute sulfuric acid. When dilute nitric acid is added to a portion of the separated precipitate, it does not dissolve. When sodium hydroxide TS is added to another portion and warmed, or when ammonium acetate TS is added to another portion, the precipitate dissolves.

(2) Solutions of lead salts yield with sodium hydroxide TS a white precipitate, which dissolves in an excess of sodium hydroxide TS, and yields a black precipitate upon subsequent addition of sodium sulfide TS.

(3) Acidic solutions of lead salts in dilute acetic acid yield with potassium chromate TS a yellow precipitate, which does not dissolve in ammonia TS but dissolves in sodium hydroxide TS subsequently added.

Lithium salt

(1) When the Flame Coloration Test (1) \( <1.04\) is applied to lithium salts, a persistent red color develops.

(2) Solutions of lithium salts yield with disodium hydrogenphosphate TS a white precipitate, which dissolves upon subsequent addition of dilute hydrochloric acid.

(3) Solutions of lithium salts yield no precipitate with dilute sulfuric acid (discrimination from strontium salts).

Magnesium salt

(1) Solutions of magnesium salts yield upon warming with ammonium carbonate TS a white precipitate, which dissolves in ammonium chloride TS. A white, crystalline precipitate is reproduced by subsequent addition of disodium hydrogenphosphate TS.

(2) Solutions of magnesium salts yield with sodium hydroxide TS a white, gelatinous precipitate. When iodine TS is added to one portion of the suspension, the precipitate develops a dark-brown color. When excess sodium hydroxide TS is added to another portion, the precipitate does not dissolve.

Manganese salt

(1) Solutions of manganese salts yield a white precipitate with ammonia TS. When silver nitrate TS is added to a portion of the suspension, the precipitate changes to black. When another portion is allowed to stand, the upper part of the precipitate exhibits a brownish color.

(2) Acidic solutions of manganese salts in dilute nitric...
acid exhibit a purple-red color with a small quantity of powdered bismuth sodium trioxide.

Mercuric salt
(1) A copper plate is immersed in solutions of mercuric salts, allowed to stand, taken out, and then washed with water. The plate becomes bright and silvery white in appearance, when rubbed with paper or cloth (common with mercuric salts).
(2) Solutions of mercuric salts yield with a small quantity of sodium sulfide TS a black precipitate, which dissolves in an excess of the reagent. The black precipitate is reproduced by subsequent addition of ammonium chloride TS.
(3) When potassium iodide TS is added dropwise to neutral solutions of mercuric salts, a red precipitate is produced. The precipitate dissolves in an excess of the reagent.
(4) Acidic solutions of mercuric salts in hydrochloric acid yield with a small quantity of tin (II) chloride TS a white precipitate, which changes to grayish black upon addition of an excess of the reagent.

Mercurous salt
(1) A copper plate is immersed in solutions of mercurous salts, allowed to stand, taken out, and then washed with water. The plate becomes bright and silvery white in appearance, when rubbed with paper or cloth (common with mercurous salts).
(2) Mercurous salts or their solutions exhibit a black color with sodium hydroxide TS.
(3) Solutions of mercurous salts yield a white precipitate with dilute hydrochloric acid. The separated precipitate changes to black upon addition of ammonium TS.
(4) Solutions of mercurous salts yield with potassium iodide TS a yellow precipitate, which changes to green, then to black upon subsequent addition of an excess of the reagent.

Mesilate
(1) To mesilates add twice its mass of sodium hydroxide, heat gently to melt, and continue heating for 20 to 30 seconds. After cooling, add a little amount of water, then add dilute hydrochloric acid, and warm: the gas evolved changes moistened potassium iodate-starch paper to blue.
(2) To mesilates add threefold its mass of sodium nitrate and anhydrous sodium carbonate, mix, and heat gradually. After cooling, dissolve the residue in diluted hydrochloric acid (1 in 5), and filter if necessary. The filtrate yields a white precipitate upon addition of barium chloride TS.

Nitrate
(1) When a solution of nitrates is mixed with an equal volume of sulfuric acid, the mixture is cooled, and iron (II) sulfate TS is superimposed, a dark brown ring is produced at the junction of the two liquids.
(2) Solutions of nitrates exhibit a blue color with diphenylamine TS.
(3) When potassium permanganate TS is added to acidic solutions of nitrates in sulfuric acid, the red-purple color of the reagent does not fade (discrimination from nitrites).

Nitrite
(1) Solutions of nitrates, when acidified with dilute sulfuric acid, evolve a yellow-brown gas with a characteristic odor. The solutions exhibit a dark brown color upon addition of a small quantity of iron (II) sulfate crystals.
(2) Solutions of nitrates, when 2 to 3 drops of potassium iodide TS and dilute sulfuric acid are added dropwise, exhibit a yellow-brown color, and then yield a black-purple precipitate. When the mixture is shaken with 2 mL of chloroform, the chloroform layer exhibits a purple color.
(3) Solutions of nitrates, when mixed with thiourea TS and acidified with dilute sulfuric acid, and iron (III) chloride TS is added dropwise, exhibit a dark red color. When the mixture is shaken with 2 mL of diethyl ether, the diethyl ether layer exhibits a red color.

Oxalate
(1) When potassium permanganate TS is added dropwise to warm acidic solutions of oxalates in sulfuric acid, the reagent is decolorized.
(2) Solutions of oxalates yield a white precipitate with calcium chloride TS. The separated precipitate does not dissolve in dilute acetic acid but dissolves upon subsequent addition of dilute hydrochloric acid.

Permanganate
(1) Solutions of permanganates exhibit a red-purple color.
(2) When an excess of hydrogen peroxide TS is added to acidic solutions of permanganates in sulfuric acid, the solutions effervescence and decolorize permanganates.
(3) Acidic solutions of permanganates in sulfuric acid are decolorized, when an excess of oxalic acid TS is added and heated.

Peroxide
(1) Solutions of peroxides are mixed with an equal volume of ethyl acetate and 1 to 2 drops of potassium dichromate TS, and then acidified with dilute sulfuric acid. When the mixture is shaken immediately and allowed to stand, the ethyl acetate layer exhibits a blue color.
(2) Acidic solutions of peroxides in sulfuric acid decolorize dropwise added potassium permanganate TS, and effervesce to evolve a gas.

Phosphate (Orthophosphate)
(1) Neutral solutions of phosphates yield with silver nitrate TS a yellow precipitate, which dissolves upon addition of dilute nitric acid or ammonia TS.
(2) Acidic solutions in dilute nitric acid of phosphates yield a yellow precipitate with hexammonium heptamolybdate TS on warming. The precipitate dissolves upon subsequent addition of sodium hydroxide TS or ammonia TS.
(3) Neutral or ammonia-alkaline solutions of phosphates yield with magnesia TS a white, crystalline precipitate, which dissolves upon subsequent addition of dilute hydrochloric acid.

Potassium salt
(1) When the Flame Coloration Test (1) applied to potassium salts, a pale purple color develops. When it gives a yellow color, a red-purple color can be seen through cobalt glass.
(2) Neutral solutions of potassium salts yield a white, crystalline precipitate with sodium hydrogen tartrate TS. The formation of the precipitate is accelerated by rubbing the inside wall of the test tube with a glass rod. The separated precipitate dissolves upon addition of any of ammonia TS, sodium hydroxide TS or sodium carbonate TS.
(3) Acidic solutions of potassium salts in acetic acid (31)...
yield a yellow precipitate with sodium hexanitrocobaltate (III) TS.

(4) Potassium salts do not evolve the odor of ammonia, when an excess of hydroxido TS is added and warmed (discrimination from ammonium salts).

Saliicylate

(1) Salicylates evolve the odor of phenol, when an excess of soda-lime is added and heated.

(2) Concentrated solutions of salicylates yield a white, crystalline precipitate with dilute hydrochloric acid. The separated precipitate, washed well with cold water and dried, melts <1.04° at about 159°C.

(3) Neutral solutions of salicylates exhibit with 5 to 6 drops of dilute iron (III) chloride TS a red color, which changes to purple and then fades when dilute hydrochloric acid is added dropwise.

Silver salt

(1) Solutions of silver salts yield a white precipitate with dilute hydrochloric acid. When dilute nitric acid is added subsequently to a portion of the suspension, the precipitate does not dissolve. When an excess of ammonia TS is added to another portion, the precipitate dissolves.

(2) Solutions of silver salts yield with potassium chromate TS a red precipitate, which dissolves upon addition of dilute nitric acid.

(3) Solutions of silver salts yield a brownish gray precipitate with ammonia TS added dropwise. When ammonia TS is added dropwise until the precipitate dissolves, then 1 to 2 drops of formaldehyde solution are added and warmed, a mirror of metallic silver is deposited on the inside wall of the container.

Sodium salt

(1) When the Flame Coloration Test (1) <1.04° is applied to sodium salts, a yellow color develops.

(2) Concentrated, neutral or slightly alkaline solutions of sodium salts yield a white, crystalline precipitate with potassium hexahydroxoantimonate (V) TS. The formation of the precipitate is accelerated by rubbing the inside wall of the test tube with a glass rod.

Stannic salt

(1) When the outside bottom of a test tube containing water is moistened with acidic solutions of stannic salts in hydrochloric acid and is placed in a nonluminous flame of a Bunsen burner, a blue flame mantle is seen around the bottom of the test tube (common with stannous salts).

(2) When granular zinc is immersed in acidic solutions of stannic salts in hydrochloric acid, a spongy, gray substance is deposited on the surface of the granules (common with stannous salts).

(3) Add iron powder to acidic solutions of stannic salts in hydrochloric acid, allow to stand, and then filter. When iodine-starch TS is added dropwise to the filtrate, the color of the test solution disappears.

(4) Acidic solutions of stannic salts in hydrochloric acid, to which ammonia TS is added dropwise until a small quantity of precipitate is produced, yield a pale yellow precipitate with 2 to 3 drops of sodium sulfide TS. The separated precipitate dissolves upon addition of sodium sulfide TS and pale yellow precipitate is reproduced by subsequent addition of hydrochloric acid.

Stannous salt

(1) When the outside bottom of a test tube containing water is moistened with acidic solutions of stannous salts in hydrochloric acid and is placed in a nonluminous flame of a Bunsen burner, a blue flame mantle is seen around the bottom of the test tube (common with stannic salts).

(2) When a solution, prepared by mixing 2 to 3 drops of a solution of resorcitol (1 in 50) and 2 to 3 drops of a solution of potassium bromide (1 in 10) with 5 mL of sulfuric acid, is added to 2 to 3 drops of solutions of tartrates, and then heated for 5 to 10 minutes on a water bath, a deep blue
color is produced. The solution exhibits a red to red-orange color when poured to 3 mL of water after cooling.

Thiocyanate

(1) Solutions of thiocyanates yield a white precipitate with an excess of silver nitrate TS. When dilute nitric acid is added to a portion of the suspension, the precipitate does not dissolve. When ammonia solution (28) is added to another portion, the precipitate dissolves.

(2) Solutions of thiocyanates produce with iron (III) chloride TS a red color, which is not decolored by addition of hydrochloric acid.

Thiosulfate

(1) When iodine TS is added dropwise to acidic solutions of thiosulfates in acetic acid (31), the color of the reagent fades.

(2) When an equal volume of dilute hydrochloric acid is added, solutions of thiosulfates evolve the odor of sulfur dioxide, and yield gradually a white turbidity, which changes to yellow on standing.

(3) Solutions of thiosulfates yield with an excess of silver nitrate TS a white precipitate, which changes to black on standing.

Zinc salt

(1) Neutral to alkaline solutions of zinc salts yield a whitish precipitate with ammonium sulfide TS or sodium sulfide TS. The separated precipitate does not dissolve in dilute acetic acid but dissolves upon subsequent addition of dilute hydrochloric acid.

(2) Solutions of zinc salts yield a white precipitate with potassium hexacyanoferrate (II) TS. When dilute hydrochloric acid is added to a portion of the suspension, the precipitate does not dissolve. When sodium hydroxide TS is added to another portion, the precipitate dissolves.

(3) Neutral to weakly acidic solutions of zinc salts yield a white precipitate, when 1 or 2 drops of pyridine and 1 mL of potassium thiocyanate TS are added.

1.10 Iron Limit Test

Iron Limit Test is a limit test for iron contained in drugs. The limit is expressed in terms of ppm in parentheses.

In each monograph, the permissible limit for iron (as Fe) is described in terms of ppm in parentheses.

1. Preparation of test solutions and control solutions

Unless otherwise specified, test solutions and control solutions are prepared as follows:

1.1. Method 1

Weigh the amount of sample specified in individual monograph, add 30 mL of acetic acid-sodium acetate buffer solution for iron limit test, pH 4.5, dissolve by warming if necessary, and designate this solution as the test solution.

Prepare the control solution as follows: To the amount of Standard Iron Solution specified in individual monograph add 20 mL of dilute hydrochloric acid, and proceed as directed for the test solution.

1.2. Method 2

Weigh the amount of sample specified in individual monograph, add 10 mL of dilute hydrochloric acid, and dissolve by warming if necessary. Dissolve 0.5 g of L-tartaric acid, and add one drop of phenolphthalein TS. Add ammonia TS dropwise until the solution develops a pale red color. Add 20 mL of acetic acid-sodium acetate buffer solution for iron limit test, pH 4.5, and designate this solution as the test solution.

Prepare the control solution as follows: To the amount of Standard Iron Solution specified in individual monograph add 10 mL of dilute hydrochloric acid, and proceed as directed for the test solution.

1.3. Method 3

Place the amount of sample specified in individual monograph in a crucible, moisten with a small amount of sulfuric acid, heat cautiously and gently at first, and then incinerate by ignition. After cooling, add 1 mL of diluted hydrochloric acid (2 in 3) and 0.5 mL of diluted nitric acid (1 in 3), evaporate on a water bath to dryness, and to the residue add 0.5 mL of diluted hydrochloric acid (2 in 3) and 10 mL of water. After dissolving by warming, add 30 mL of acetic acid-sodium acetate buffer solution for iron limit test, pH 4.5, and designate this solution as the test solution.

Prepare the control solution as follows: Transfer the amount of Standard Iron Solution specified in individual monograph to a crucible, and add 1 mL of diluted hydrochloric acid (2 in 3) and 0.5 mL of diluted nitric acid (1 in 3), evaporate on a water bath to dryness, and proceed as directed for the test solution.

In this procedure, use a quartz or porcelain crucible, which is immersed in boiling dilute hydrochloric acid for 1 hour and washed throughly with water and dried.

2. Procedure

Unless otherwise specified, proceed as follows:

2.1. Method A

Transfer the test solution and the control solution to separate Nessler tubes, to each add 2 mL of a solution of L-ascorbic acid (1 in 100), mix well, and allow to stand for 30 minutes. Add 1 mL of a solution of α, α′-dipyridyl in ethanol (95) (1 in 200), add water to make 50 mL, and allow to stand for 30 minutes. Then compare the colors developed in both solutions against a white background. The test solution has no more color than the control solution.

2.2. Method B

Dissolve 0.2 g of L-ascorbic acid in the test solution and the control solution, and allow to stand for 30 minutes. Add 1 mL of a solution of α, α′-dipyridyl in ethanol (95) (1 in 200), and allow to stand for 30 minutes. Then add 2 mL of a solution of 2,4,6-trinitrophenol (3 in 1000) and 20 mL of 1,2-dichloroethane, shake vigorously, collect the 1,2-dichloroethane layer, and filter through a pledge of absorbent cotton in a funnel on which 5 g of anhydrous sodium sulfate is placed if necessary. Then compare the colors developed in both solutions against a white background. The test solution has no more color than the control solution.

1.11 Arsenic Limit Test

Arsenic Limit Test is a limit test for arsenic contained in drugs. The limit is expressed in terms of arsenic (III) trioxide (As2O3).

In each monograph, the permissible limit for arsenic (as As2O3) is described in terms of ppm in parentheses.
1. Apparatus
   Use the apparatus illustrated in Fig. 1.11-1.
   Place glass wool F in the exit tube B up to about 30 mm in height, moisten the glass wool uniformly with a mixture of an equal volume of lead (II) acetate TS and water, and apply gentle suction to the lower end to remove the excess of the mixture. Insert the tube vertically into the center of the rubber stopper H, and attach the tube to the generator bottle A so that the small perforation E in the lower end of B extends slightly below. At the upper end of B, attach the rubber stopper J to hold the tube C vertically. Make the lower end to the exit tube of C level with that of the rubber stopper J.

2. Preparation of the test solution
   Unless otherwise specified, proceed as directed in the following.
   2.1. Method 1
   Weigh the amount of the sample directed in the monograph, add 5 mL of water, dissolve by heating if necessary, and designate the solution as the test solution.
   2.2. Method 2
   Weigh the amount of the sample directed in the monograph, add 5 mL of water, and add 1 mL of sulfuric acid except in the cases that the samples are inorganic acids. Add 10 mL of sulfurous acid solution, transfer to a small beaker, and evaporate the mixture on a water bath until it is free from sulfurous acid and is reduced to about 2 mL in volume. Dilute with water to make 5 mL, and designate it as the test solution.
   2.3. Method 3
   Weigh the amount of the sample directed in the monograph, and place it in a crucible of platinum, quartz or porcelain. Add 10 mL of a solution of magnesium nitrate hexahydrate in ethanol (95) (1 in 50), ignite the ethanol, and heat gradually to incinerate. If carbonized material still remains by this procedure, moisten with a small quantity of nitric acid, and ignite again to incinerate. After cooling, add 3 mL of hydrochloric acid, heat on a water bath to dissolve the residue, and designate it as the test solution.
   2.4. Method 4
   Weigh the amount of the sample directed in the monograph, and place it in a crucible of platinum, quartz or porcelain. Add 10 mL of a solution of magnesium nitrate hexahydrate in ethanol (95) (1 in 10), burn the ethanol, heat gradually, and ignite to incinerate. If carbonized material still remains by this procedure, moisten with a small quantity of nitric acid, and ignite again to incinerate in the same manner. After cooling, add 3 mL of hydrochloric acid, heat on a water bath to dissolve the residue, and designate it as the test solution.
   2.5. Method 5
   Weigh the amount of the sample directed in the monograph, add 10 mL of N,N-dimethylformamide, dissolve by heating if necessary, and designate the solution as the test solution.

3. Test solutions
   Absorbing solution for hydrogen arsenide: Dissolve 0.50 g of silver N,N-diethyldithiocarbamate in pyridine to make 100 mL. Preserve this solution in a glass-stoppered bottle protected from light, in a cold place.
   Standard Arsenic Stock Solution: Weigh accurately 0.100 g of finely powdered arsenic (III) trioxide dried at 105°C for 4 hours, and add 5 mL of sodium hydroxide solu-
tion (1 in 5) to dissolve. Add dilute sulfuric acid to neutralize, add further 10 mL of dilute sulfuric acid, and add freshly boiled and cooled water to make exactly 1000 mL.

Standard Arsenic Solution: Pipet 10 mL of Standard Arsenic Stock Solution, add 10 mL of dilute sulfuric acid, and add freshly boiled and cooled water to make exactly 1000 mL. Each mL of the solution contains 1 µg of arsenic (III) trioxide (As₂O₃). Prepare Standard Arsenic Solution just before use and preserve in a glass-stoppered bottle.

4. Procedure

Unless otherwise specified, proceed using apparatus shown in Fig. 1.11-1. Carry out the preparation of the standard color at the same time.

Place the test solution in the generator bottle A and, if necessary, wash down the solution in a bottle with a small quantity of water. Add 1 drop of methyl orange TS, and after neutralizing with ammonia TS, ammonia solution (28%) or dilute hydrochloric acid, add 5 mL of diluted hydrochloric acid (1 in 2) and 5 mL of potassium iodide TS, and allow to stand for 2 to 3 minutes. Add 5 mL of acidic tin (II) chloride TS, and allow to stand for 10 minutes. Then add water to make 40 mL, add 2 g of zinc for arsenic analysis, and immediately connect the rubber stopper H fitted with B and C with the generator bottle A. Transfer 5 mL of the absorbing solution for hydrogen arsenide to the absorber tube D, insert the tip of C to the bottom of the absorber tube D, then immerse the generator bottle A up to the shoulder in water maintained at 25°C, and allow to stand for 1 hour. Disconnect the absorber tube, add pyridine to make 5 mL, if necessary, and observe the color of the absorbing solution: the color produced corresponds to 2 µg of arsenic (III) trioxide (As₂O₃) and is used as the standard.

5. Note

Apparatus, reagents and test solutions used in the test should contain little or no arsenic. If necessary, perform a blank determination.

1.12 Methanol Test

Methanol Test is a method to determine methanol adhering in ethanol.

1. Reagents

(i) Standard Methanol Solution—To 1.0 g of methanol, accurately measured, add water to make exactly 1000 mL. To 5 mL of this solution, exactly measured, add 2.5 mL of methanol-free ethanol and water to make exactly 50 mL.

(ii) Solution A—To 75 mL of phosphoric acid add water to make 500 mL, then dissolve 15 g of potassium permanganate in this solution.

(iii) Solution B—Add sulfuric acid carefully to an equal volume of water, cool, and dissolve 25 g of oxalic acid hydrate in 500 mL of this dilute sulfuric acid.

2. Procedure

Pipet 1 mL of the sample, and add water to make exactly 20 mL. Use this solution as the sample solution. Transfer 5 mL each of the sample solution and the Standard Methanol Solution, accurately measured, to test tubes, add 2 mL of Solution A to each solution, and allow to stand for 15 minutes. Decolorize these solutions by adding 2 mL of Solution B, and mix with 5 mL of fuchsin-sulfurous acid TS. Allow to stand for 30 minutes at ordinary temperature. The sample solution has no more color than the Standard Methanol Solution.

1.13 Fats and Fatty Oils Test

Fats and Fatty Oils Test is a method applied to fats, fatty oils, waxes, fatty acids, higher alcohols, and related substances.

1. Preparation of test sample

For a solid sample, melt with care, and, if necessary, filter the melted sample with a dry filter paper by warming. For a turbid liquid sample, heat at about 50°C. If it is still turbid, filter it with a dry filter paper while warm. In either case, mix the sample to make it homogeneous.

2. Melting point

Proceed by the method described in Method 2 of Melting Point Determination (2.60).

3. Congealing point of fatty acids

3.1. Preparation of fatty acids

Dissolve 25 g of potassium hydroxide in 100 g of glycerin. Transfer 75 g of this solution into a 1-L beaker, and heat at 150°C. Add 50 g of the sample to this solution, and heat at a temperature not higher than 150°C for 15 minutes under frequent stirring to saponify completely. Cool the solution to 100°C, dissolve by addition of 500 mL of hot water, and add slowly 50 mL of diluted sulfuric acid (1 in 4). Heat the solution under frequent stirring until the clear layer of fatty acid is separated distinctly. Separate the fatty acid layer, and wash the fatty acid layer with hot water until the washing shows no acidity to methyl orange TS. Transfer the fatty acid layer to a small beaker, and heat on a water bath until the fatty acid becomes clear owing to the separation of water. Filter the warm solution, and complete the evaporation of water by carefully heating the filtered solution to 130°C.

3.2. Measurement of congealing point

Proceed by the method described in Congealing Point Determination (2.42).

4. Specific gravity

4.1. Liquid sample at ordinary temperature

Proceed by the method described in Determination of Specific Gravity and Density (2.56).

4.2. Solid sample at ordinary temperature

Unless otherwise specified, fill a pycnometer with water at 20°C. Weigh accurately the pycnometer, and, after discarding the water and drying, weigh accurately the empty pycnometer. Then, fill the pycnometer with the melted sample to about three-fourths of the depth, and allow to stand at a temperature a little higher than the melting temperature of the sample for 1 hour to drive off the air in the sample. After keeping at the specified temperature, weigh accurately the
5. **Acid value**

The acid value is the number of milligrams of potassium hydroxide (KOH) required to neutralize the free acids in 1 g of sample.

### 5.1. Procedure

Unless otherwise specified, weigh accurately the amount of sample shown in Table 1.13-1, according to the expected acid value of the sample, in a glass-stoppered, 250-mL flask, add 100 mL of a mixture of diethyl ether and ethanol (95:1:1 or 2:1) as the solvent, and dissolve the sample by warming, if necessary. Then, add a few drops of phenolphthalein TS as an indicator, and add 0.1 mol/L potassium hydroxide-ethanol VS until the solution develops a light red color which persists for 30 seconds. If the sample solutions is turbid at lower temperature, titration should be done while warm. To the solvent used add phenolphthalein TS as an indicator, and add 0.1 mol/L potassium hydroxide-ethanol VS before use, until the solvent remains light red for 30 seconds.

\[
d = \frac{M_1 - M}{(M_2 - M_1) - (M_3 - M_2)}
\]

- \(d\): mass (g) of the empty pycnometer
- \(M\): Mass (g) of the pycnometer filled with water
- \(M_1\): Mass (g) of the pycnometer filled with the sample
- \(M_2\): Mass (g) of the pycnometer filled with water
- \(M_3\): Mass (g) of the pycnometer filled with the sample and water

6. **Saponification value**

The saponification value is the number of milligrams of potassium hydroxide (KOH) required to saponify the esters in 1 g of sample.

### 6.1. Procedure

Unless otherwise specified, weigh accurately 1 to 2 g of the sample, transfer to a 200-mL flask, and add exactly 25 mL of 0.5 mol/L potassium hydroxide-ethanol VS. Attach a medium reflux condenser or an air condenser 750 mm in length and 6 mm in diameter to the neck of the flask, and heat gently in a water bath for 1 hour with frequent shaking. Cool the solution, add 1 mL of phenolphthalein TS, and titrate \(\leq 2.5\) with 0.1 mol/L potassium hydroxide-ethanol VS until the solution develops a light red color which persists for 30 seconds. If the sample solutions is turbid at lower temperature, titration should be done while warm. Perform a blank determination.

\[
\text{Acid value} = \frac{\text{consumed volume (mL) of 0.1 mol/L potassium hydroxide-ethanol VS} \times 5.611}{\text{amount (g) of sample}}
\]

### Table 1.13-1

7. **Ester value**

The ester value is the number of milligrams of potassium hydroxide (KOH) required to saponify the esters in 1 g of sample.

### 7.1. Procedure

Unless otherwise specified, designate the difference between the saponification value and the acid value determined as the ester value.

8. **Hydroxyl value**

The hydroxyl value is the number of milligrams of potassium hydroxide (KOH) required to neutralize acetic acid combined with hydroxyl groups, when 1 g of the sample is acetylated by the following procedure.

### 8.1. Procedure

Place about 1 g of the sample, weighed accurately, in a 200-mL round-bottom flask (shown in Fig. 1.13-1), and add exactly 5 mL of pyridine-acetic anhydride TS. Place a small funnel on the neck of the flask, and heat by immersing the flask up to 1 cm from the bottom in an oil bath between 95°C and 100°C. Put a thick, round paper with a round hole on the joint of the neck of the flask to protect the neck from the heat of the oil bath. After heating for 1 hour, take the flask from the oil bath, and cool by standing. Add 1 mL of water to the flask, and shake to decompose acetic anhydride. Heat the flask in the oil bath for 10 minutes again. After cooling, wash the funnel and neck with 5 mL of neutralized ethanol down into the flask, and titrate \(\leq 2.5\) with 0.5 mol/L potassium hydroxide-ethanol VS (indicator: 1 mL of phenolphthalein TS). Perform a blank determination.

\[
\text{Hydroxyl value} = \frac{(a - b) \times 28.05}{\text{amount (g) of sample}} + \text{acid value}
\]

- \(a\): Volume (mL) of 0.5 mol/L hydrochloric acid VS consumed in the blank determination
- \(b\): Volume (mL) of 0.5 mol/L hydrochloric acid VS consumed for titration of the sample

![Image](image-url)
9. Unsaponifiable matter

Unsaponifiable matter is calculated as the difference between the amount of materials, which are unsaponifiable by the procedure described below, soluble in diethyl ether and insoluble in water, and the amount of fatty acids expressed in terms of the amount of oleic acid. Its limit is expressed as a percentage in the monograph.

9.1. Procedure

Transfer about 5 g of the sample, accurately weighed, to a 250-mL flask. Add 50 mL of potassium hydroxide-ethanol TS, attach a reflux condenser to the flask, boil gently on a water bath for 1 hour with frequent shaking, and then transfer to the first separator. Wash the flask with 100 mL of warm water, and transfer the washing to the separator. Further, add 50 mL of water to the separator, and cool to room temperature. Wash the flask with 100 mL of diethyl ether, add the washing to the separator, extract by vigorous shaking for 1 minute, and allow to stand until both layers are separated clearly. Transfer the water layer to the second separator, add 50 mL of diethyl ether, shake, and allow to stand in the same manner. Transfer the water layer in the second separator to the third separator, add 50 mL of diethyl ether, and extract by shaking again in the same manner. Combine the diethyl ether extracts in the second and third separators into the first separator, wash each separator with 50 mL of diethyl ether, and extract by shaking again in the same manner. Combine the diethyl ether extracts in the second and third separators into the first separator, wash each separator with a small amount of diethyl ether, and combine the washings into the first separator. Wash the combined extracts in the first separator with 30 mL portions of water successively, until the washing does not develop a light red color with 2 drops of phenolphthalein TS. Add a small amount of anhydrous sodium sulfate to the diethyl ether extracts, and allow to stand for 1 hour. Filter the diethyl ether extracts with dry filter paper, and collect the filtrates into a tared flask. Wash the flask with 100 mL of diethyl ether, and extract by shaking again in the same manner. Combine the diethyl ether extracts in the second and third separators into the first separator, wash each separator with a small amount of diethyl ether, and add the washing to the flask through the above filter paper. After evaporation of the filtrate and washing almost to dryness on a water bath, add 3 mL of acetone, and evaporate again to dryness on a water bath. Complete the drying between 70°C and 80°C under reduced pressure (about 2.67 kPa) for 30 minutes, allow to stand for cooling in a desiccator (reduced pressure, silica gel) for 30 minutes, and then weigh. After weighing, add 2 mL of potassium chloride solution (1 in 10 and 100 mL of water, and shake. Then, titrate $2.50\text{mL}$ the liberated iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS). Perform a blank determination.

\[
\text{Iodine value} = \frac{(a - b) \times 1.269}{\text{amount (g) of sample}}
\]

\[
a: \text{Volume (mL) of 0.1 mol/L sodium thiosulfate VS consumed in the blank determination}
\]

\[
b: \text{Volume (mL) of 0.1 mol/L sodium thiosulfate VS consumed for titration of the sample}
\]

10. Iodine value

The iodine value, when measured under the following conditions, is the number of grams of iodine (I), representing the corresponding amount of halogen, which combines with 100 g of sample.

10.1. Procedure

Unless otherwise specified, weigh accurately the amount of sample shown in Table 1.13-2, according to the expected iodine value of the sample, in a small glass container. In a 500-mL glass-stoppered flask place the container containing the sample, add 20 mL of cyclohexane to dissolve the sample, then add exactly 25 mL of Wijs TS, and mix well. Stopper the flask, and allow to stand, protecting against light, between 20°C and 30°C for 30 minutes (when the expected iodine value is more than 100, for 1 hour) with occasional shaking. Add 20 mL of potassium iodoide solution (1 in 10) and 100 mL of water, and shake. Then, titrate $2.50\text{mL}$ the liberated iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS). Perform a blank determination.

\[
\text{Iodine value} = \frac{(a - b) \times 1.269}{\text{amount (g) of sample}}
\]

\[
a: \text{Volume (mL) of 0.1 mol/L sodium thiosulfate VS consumed in the blank determination}
\]

\[
b: \text{Volume (mL) of 0.1 mol/L sodium thiosulfate VS consumed for titration of the sample}
\]

1.14 Sulfate Limit Test

Sulfate Limit Test is a limit test for sulfate contained in drugs.

In each monograph, the permissible limit for sulfate (as SO₄) is described in terms of percentage (%) in parentheses.

1. Procedure

Unless otherwise specified, transfer the quantity of the sample, directed in the monograph, to a Nessler tube, dissolve it in sufficient water, and add water to make 40 mL. Add 1 mL of dilute hydrochloric acid and water to make 50 mL, and use this solution as the test solution. Transfer the volume of 0.005 mol/L sulfuric acid VS, directed in the monograph, to another Nessler tube, add 1 mL of dilute hydrochloric acid and water to make 50 mL, and use this solution as the control solution. When the test solution is not clear, filter both solutions according to the same procedure. Add 2 mL of barium chloride TS to the test solution and to the control solution, mix well, and allow to stand for 10 minutes. Compare the white turbidity produced in both solutions against a black background by viewing downward or transversely.

The turbidity produced in the test solution is not thicker than that of the control solution.

1.15 Readily Carbonizable Substances Test

Readily Carbonizable Substances Test is a method to examine the minute impurities contained in drugs, which are readily colored by addition of sulfuric acid.
1. Procedure
Before use, wash the Nessler tubes thoroughly with sulfuric acid for readily carbonizable substances. Unless otherwise specified, proceed as follows. When the sample is solid, place 5 mL of sulfuric acid for readily carbonizable substances in a Nessler tube, to which add a quantity of the finely powdered sample, little by little, as directed in the monograph, and dissolve it completely by stirring with a glass rod. When the sample is liquid, transfer a volume of the sample, as directed in the monograph, to a Nessler tube, add 5 mL of sulfuric acid for readily carbonizable substances, and mix by shaking. If the temperature of the content of the tube rises, cool the content; maintain it at the standard temperature, if the reaction may be affected by the temperature. Allow to stand for 15 minutes, and compare the color of the liquid with that of the matching fluid in the Nessler tube specified in the monograph, by viewing transversely against a white background.

2. Physical Methods

Chromatography

2.01 Liquid Chromatography

Liquid Chromatography is a method to develop a mixture injected into a column prepared with a suitable stationary phase by passing a liquid as a mobile phase through the column, in order to separate the mixture into its components by making use of the difference of retention capacity against the stationary phase, and to determine the components. This method can be applied to a liquid or soluble sample, and is used for identification, purity test, and quantitative determination.

A mixture injected into the column is distributed between the mobile phase and the stationary phase with a characteristic ratio (k) for each component.

\[
k = \frac{\text{amount of compound in the stationary phase}}{\text{amount of compound in the mobile phase}}
\]

The ratio k represents the mass distribution ratio in liquid chromatography.

Since the relation given below exists among the ratio (k), the time for which the mobile phase is passed through the column \( t_0 \) (time measured from the time of injection of a compound with \( k = 0 \) to the time of elution at the peak maximum), and the retention time \( t_R \) (time measured from the time of injection of a compound to be determined to the time of elution at the peak maximum), the retention time for a compound on a column has a characteristic value under fixed chromatographic conditions.

\[
t_R = (1 + k) \cdot t_0
\]

1. Apparatus

Basically, the apparatus required for the liquid chromatographic procedure consists of a pumping system for the mobile phase, a sample injection port, a column, a detector and a recorder. A mobile phase component regulator, a thermostat for the column, a pumping system for reaction reagents and a chemical reaction chamber are also used, if necessary. The pumping system serves to deliver the mobile phase and the reagents into the column and connecting tube at a constant flow rate. The sample injection port is used to deliver a quantity of the sample to the apparatus with high reproducibility. The column is a tube with a smooth interior, made of inert metal, etc., in which a packing material for liquid chromatography is uniformly packed. A column with a stationary phase chemically bound on the inside wall instead of the column packed with the packing material may be used. The detector is used to detect a property of the samples which is different from that of the mobile phase, and may be an ultraviolet or visible spectrophotometer, fluorometric detector, differential refractometer, electrochemical detector, chemiluminescence detector, electric conductivity detector, mass spectrophotometer, etc. The output signal is usually proportional to the concentration of samples at amounts of less than a few µg. The recorder is used to record the output signals of the detector. As required, a data processor may be used as the recorder to record or output the chromatogram, retention times or amounts of the components. The mobile phase component regulator is used to vary the ratio of the mobile phase components in a stepwise or gradient fashion.

2. Procedure

Fix the detector, column and mobile phase to the apparatus, and adjust the flow rate and the column temperature to the values described in the operating conditions specified in the individual monograph. Inject a volume of the sample solution or the standard solution specified in the individual monograph with the sample injector into the column through the sample injection port. The separated components are detected by the detector, and recorded by the recorder as a chromatogram. If the components to be analyzed have no readily detectable physical properties such as absorbance or fluorescence, the detection is achieved by changing the components to suitable derivatives. Usually, the derivatization is performed as a pre- or post-column labeling.

3. Identification and purity test

When Liquid Chromatography is used for identification of a component of a sample, it is performed by confirming identity of the retention time of the component and that of an authentic specimen, or by confirming that the peak shape of the component is unchanged after mixing the sample with an authentic specimen. If a detector which is able to obtain chemical structural information of the component at the same time is used, highly specific identification can be achieved by confirming identity of the chemical structure of the component and that of an authentic specimen, in addition to the identity of their retention times.

When Liquid Chromatography is used for purity test, it is generally performed by comparing the peak area of target impurity from the sample solution with that of the main component from a standard solution, which is prepared by diluting the sample solution to a concentration corresponding to the specified limit of the impurity, or by calculating target impurity content using the peak area percentage method. Unless otherwise specified, if a sample is separated into isomers in the chromatogram, the isomer ratio is calculated by using the peak area percentage method.
The peak area percentage method is a method to calculate the proportion of the components from the ratio of the peak area of each component to the sum of the peak areas of every peak recorded in the chromatogram. In order to obtain accurate results in evaluating the proportion of the components, it is necessary to correct the area of each component based on its relative response factor to the principal component.

4. Assay

4.1. Internal standard method

In the internal standard method, choose a stable compound as an internal standard which shows a retention time close to that of the compound to be assayed, and whose peak is well separated from all other peaks in the chromatogram. Prepare several kinds of standard solutions containing a fixed amount of the internal standard and several graded amounts of the authentic specimen specified in the individual monograph. Based on the chromatogram obtained by injection of a fixed volume of individual standard solutions, calculate the ratio of peak area or peak height of the authentic specimen to that of the internal standard, and prepare a calibration curve by plotting these ratios on the ordinate against the amount of the authentic specimen or the ratio of the amount of the authentic specimen to that of the internal standard on the abscissa. The calibration curve is usually obtained as a straight line passing through the origin. Then, prepare a sample solution containing the internal standard in the same amount as in the standard solutions used for the preparation of the calibration curve according to the method specified in the individual monograph, perform the liquid chromatography under the same operating conditions as for the preparation of the calibration curve, calculate the ratio of the peak area or peak height of the objective compound to that of the internal standard, and read the amount of the compound from the calibration curve.

In an individual monograph, generally one of the standard solutions with a concentration within the linear range of the calibration curve and a sample solution with a concentration close to that of the standard solution are prepared, and the chromatography is performed with these solutions under fixed conditions to determine the amount of the objective compound.

4.2. Absolute calibration curve method

Prepare standard solutions with several graded amounts of the authentic specimen, and inject accurately a fixed volume of these standard solutions. With the chromatogram obtained, prepare a calibration curve by plotting the peak areas or peak heights on the ordinate against the amount of the authentic specimen on the abscissa. The calibration curve obtained, prepare a calibration curve by plotting the peak volume of these standard solutions. With the chromatogram of the authentic specimen, and inject accurately a fixed amount of the compound as an internal standard which shows a retention time close to that of the compound to be assayed, and whose peak is well separated from all other peaks in the chromatogram. Prepare several kinds of standard solutions containing a fixed amount of the internal standard and several graded amounts of the authentic specimen specified in the individual monograph. Based on the chromatogram obtained by injection of a fixed volume of individual standard solutions, calculate the ratio of peak area or peak height of the authentic specimen to that of the internal standard, and prepare a calibration curve by plotting these ratios on the ordinate against the amount of the authentic specimen or the ratio of the amount of the authentic specimen to that of the internal standard on the abscissa. The calibration curve is usually obtained as a straight line passing through the origin. Then, prepare a sample solution containing the internal standard in the same amount as in the standard solutions used for the preparation of the calibration curve according to the method specified in the individual monograph, perform the liquid chromatography under the same operating conditions as for the preparation of the calibration curve, calculate the ratio of the peak area or peak height of the objective compound to that of the internal standard, and read the amount of the compound from the calibration curve.

In an individual monograph, generally one of the standard solutions with a concentration within the linear range of the calibration curve and a sample solution with a concentration close to that of the standard solution are prepared, and the chromatography is performed with these solutions under fixed conditions to determine the amount of the objective compound. In this method, all procedures, such as the injection procedure, must be carried out under a strictly constant condition.

5. Method for peak measuring

5.1. Peak height measuring method

(i) Peak height method: Measure the distance between the maximum of the peak and the intersecting point of a perpendicular line from the maximum of the peak to the horizontal axis of recording paper with a tangent linking the baselines on both sides of the peak. (ii) Automatic peak height method: Measure the signals from the detector as the peak height using a data processing system.

5.2. Peak area measuring method

(i) Width at half-height method: Multiply the peak width at the half-height by the peak height. (ii) Automatic integration method: Measure the signals from the detector as the peak area using a data processing system.

6. System suitability

System suitability testing is an integral part of test methods using chromatography, and is used to ensure that the performance of the chromatographic systems used is as suitable for the analysis of the drug as was at the time when the verification of the test method was performed using the system. System suitability testing should be carried out at every series of drug analysis. The test procedures and acceptance criteria of system suitability testing must be prescribed in the test method of drugs. The results of drug analyses are not acceptable unless the requirements of system suitability have been met.

In system suitability testing of the chromatographic systems, the evaluation of “System performance” and “System repeatability” is usually required. For quantitative purity tests, the evaluation of “Test for required detectability” may also be required.

6.1. Test for required detectability

For purity tests, when it is confirmed that the target impurity is distinctly detected at the concentration of its specification limit, it is considered verified that the system used has adequate performance to achieve its intended use.

For quantitative purity tests, “Test for required detectability” is usually required, and in order to confirm, in some degree, the linearity of response near its specification limit, the range of expected response to the injection of a certain volume of target impurity solution at the concentration of its specification limit should be prescribed. For limit test, “Test for required detectability” is not required, if the test is performed by comparing the response from sample solution with that from standard solution at the concentration of its specification limit. “Test for required detectability” is also not required, if it is confirmed that the impurity can be detected at its specification limit by the evaluation of “System repeatability” or some other procedure.

6.2. System performance

When it is confirmed that the specificity for determining the test ingredient is ensured, it is considered verified that the system used has adequate performance to achieve its intended use.

In assay, “System performance” should be defined by the resolution between the test ingredient and a target substance to be separated (a closely eluting compound is preferable),
and when appropriate, by their order of elution. In purity tests, both the resolution and the order of elution between the test ingredient and a target substance to be separated (a closely eluting compound is preferable) should be prescribed. In addition, if necessary, the symmetry factor of the test ingredient should be prescribed together with them. However, if there is no suitable target substance to be separated, it is acceptable to define “System performance” using the number of theoretical plates and the symmetry factor of the test ingredient.

6.3. System repeatability

When it is confirmed that the degree of variation (precision) of the response of the test ingredient is at a level that meets the requirement of “System repeatability”, it is considered verified that the system used has adequate performance to achieve its intended use.

The allowable limit of “System repeatability” is normally defined as the relative standard deviation (RSD) of the response of the test ingredient in replicate injections of standard solution. It is acceptable to confirm the repeatability of the system not only by replicate injections of standard solution before sample injections, but also by divided injections of standard solution before and after sample injections, or by interspersed injections of standard solution among sample injections.

In principle, total number of replicate injections should be 6. However, in the case that a long time is necessary for one analysis, such as the analysis using the gradient method, or the analysis of samples containing late eluting components, it may be acceptable to decrease the number of replicate injections by adopting new allowable limit of “System repeatability” which can guarantee a level of “System repeatability” equivalent to that at 6 replicate injections.

The allowable limit of “System repeatability” should be set at an appropriate level based on the data when suitability of the method for the evaluation of quality of the drug was verified, and the precision necessary for the quality test.

7. Point to consider on changing the operating conditions

Among the operating conditions specified in the individual monograph, inside diameter and length of the column, particle size of the packing material, column temperature, composition ratio of the mobile phase, pH of the mobile phase, concentration ratio of the mobile phase, composition of buffer solution before sample injections, but also by divided injections of standard solution before and after sample injections, or by interspersed injections of standard solution among sample injections.

In principle, total number of replicate injections should be 6. However, in the case that a long time is necessary for one analysis, such as the analysis using the gradient method, or the analysis of samples containing late eluting components, it may be acceptable to decrease the number of replicate injections by adopting new allowable limit of “System repeatability” which can guarantee a level of “System repeatability” equivalent to that at 6 replicate injections.

The allowable limit of “System repeatability” should be set at an appropriate level based on the data when suitability of the method for the evaluation of quality of the drug was verified, and the precision necessary for the quality test.

7. Point to consider on changing the operating conditions

Among the operating conditions specified in the individual monograph, inside diameter and length of the column, particle size of the packing material, column temperature, composition ratio of the mobile phase, pH of the mobile phase, concentration of ion-pair forming agents in the mobile phase, ionic strength of the mobile phase, flow rate of the mobile phase, number and timing of mobile phase composition changes in gradient program, flow rate of mobile phase in gradient program, composition and flow rate of derivatizing reagents, and reaction time and chamber temperature in chemical reaction may be modified within the ranges in which the liquid chromatographic system used conforms to the requirements of system suitability.

8. Terminology

(i) SN ratio: It is defined by the following formula.

\[
S/N = \frac{2H}{h}
\]

\(H\): Peak height of the target ingredient peak from the baseline (the median value of background noise)

\(h\): Width of background noise of the chromatogram of sample solution or solvent blank around the peak of the target ingredient

The baseline and background noise are measured over a range 20 times of peak width at the center point of peak height of the target ingredient. When a solvent blank is used, measure over almost the same range as mentioned above around the point where the target ingredient elutes.

(ii) Symmetry factor: It shows the degree of symmetry of a peak in the chromatogram, and is defined as \(S\) in the following equation.

\[
S = \frac{W_{0.05h}}{2f}
\]

\(W_{0.05h}\): Width of the peak at one-twentieth of the peak height

\(f\): Distance between the perpendicular from the peak maximum and the leading edge of the peak at one-twentieth of the peak height

Where \(W_{0.05h}\) and \(f\) have the same unit.

(iii) Relative standard deviation: Generally, it is defined as RSD (%) in the following equation.

\[
\text{RSD} (\%) = \frac{100}{\bar{X}} \times \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{X})^2}{n - 1}}
\]

\(x_i\): Observed value

\(\bar{X}\): Mean of observed values

\(n\): Number of replicate measurements

(iv) Complete separation of peak: It means that the resolution between two peaks is not less than 1.5. It is also called as “baseline separation”.

(v) Peak-valley ratio: It indicates the degree of separation between 2 peaks on a chromatogram when baseline separation cannot be attained, and is defined as \(p/v\) by the following formula.

\[
p/v = \frac{H_p}{H_v}
\]

\(H_p\): peak height from the baseline of the minor peak

\(H_v\): height from the baseline of the lowest point (peak valley) of the curve between major and minor peaks

(vi) Separation factor: It shows the relation between the retention times of peaks in the chromatogram, and is defined as \(\alpha\) in the following equation.
Gas Chromatography is a method to develop a mixture injected into a column prepared with a suitable stationary phase by passing a gas (carrier gas) as a mobile phase through the column, in order to separate the mixture into its components by making use of the difference of retention capacity against the stationary phase, and to determine the components. This method can be applied to a gaseous or vaporizable sample, and is used for identification, purity test, and quantitative determination.

A mixture injected into the column is distributed between the mobile phase and the stationary phase with a characteristic ratio \( (k) \) for each component.

\[
k = \frac{\text{amount of compound in the stationary phase}}{\text{amount of compound in the mobile phase}}
\]

Since the relation given below exists among the ratio \( (k) \), the time for which the mobile phase is passed through the column \( t_0 \): time measured from the time of injection of a compound with \( k = 0 \) to the time of elution at the peak maximum, and the retention time \( t_R \): time measured from the time of injection of a compound to be determined to the time of elution at the peak maximum), the retention time for a compound on a column has a characteristic value under fixed chromatographic conditions.

\[
t_R = (1 + k) t_0
\]

1. Apparatus

Basically, the apparatus required for the gas chromatographic procedure consists of a carrier gas-introducing port and flow regulator, a sample injection port, a column, a column oven, a detector and a recorder. Gas introducing port and flow regulator for a combustion gas, a burning supporting gas and an accessory gas and sample injection port for headspace are also used, if necessary. The carrier gas-introducing port and flow regulator serves to deliver the carrier gas into the column at a constant flow rate, and usually consist of a pressure regulation valve, a flow rate regulation valve and a pressure gauge. The sample injection port is used to deliver a quantity of the sample to the flow line of carrier gas with high reproducibility. There are sample injection ports for packed column and for capillary column. There are both divided injection mode and non-divided injection mode to sample injection port for capillary column. The columns are usually classified as packed column or capillary column. The packed column is a tube made of inert metal, glass or synthetic resin, in which a packing material for gas chromatography is uniformly packed. The packed column with not more than 1 mm in inside diameter is also called a packed capillary column (micro packed column). A capillary column is a tube made of inert metal, glass, quartz or synthetic resin, whose inside wall is bound chemically with stationary phase for gas chromatography. The column oven has the setting capacity for a column with required length and the temperature regulation system for keeping the constant column temperature. The detector is used to detect a component separated on the column, and may be an alkaline thermal ionization detector, a flame photometry detector, mass spectrometrometer, hydrogen flame-ionization detector, an electron capture detector, a thermal conductivity detector, etc. The recorder is used to record the output signals of the detector.

2. Procedure

Unless otherwise specified, proceed by the following method. Fix the detector, column and carrier gas to the apparatus, and adjust the flow rate and the column temperature to the values described in the operating conditions speci-
3. Identification and purity test

Identification of a component of a sample is performed by confirming identity of the retention time of the component and that of an authentic specimen, or by confirming that the peak shape of the component is unchanged after mixing the sample with an authentic specimen.

In general, the purity of the sample is determined by comparing the peak area of target impurity from the sample solution with that of the main component from a standard solution, which is prepared by diluting the sample solution to a concentration corresponding to the specified limit of the impurity, or by calculating target impurity content using the peak area percentage method. Unless otherwise specified, if a sample is separated into isomers in the chromatogram, the isomer ratio is calculated by using the peak area percentage method.

The peak area percentage method is a method to calculate the proportion of the components from the ratio of the peak area of each component to the sum of the peak areas of every peak recorded in the chromatogram. In order to obtain accurate results in evaluating the proportion of the components, it is necessary to correct the area of each component based on its response factor to the principal component.

4. Assay

In general, perform the assay by using the internal standard method. The absolute calibration curve method is used when a suitable internal standard is not available. Perform the assay by using the standard addition method when the effect of the component other than the compound to be assayed on the quantitative determination is not negligible against a result of the determination.

4.1. Internal standard method

In the internal standard method, choose a stable compound as an internal standard which shows a retention time close to that of the compound to be assayed, and whose peak is well separated from all other peaks in the chromatogram. Prepare several kinds of standard solutions containing a fixed amount of the internal standard and several graded amounts of the authentic specimen specified in the individual monograph. Based on the chromatogram obtained by injection of a fixed volume of individual standard solutions, calculate the ratio of peak area or peak height of the authentic specimen to that of the internal standard, and prepare a calibration curve by plotting these ratios on the ordinate against the amount of the authentic specimen or the ratio of the amount of the authentic specimen to that of the internal standard on the abscissa. The calibration curve is usually obtained as a straight line passing through the origin. Then, prepare a sample solution containing the internal standard in the same amount as in the standard solutions used for the preparation of the calibration curve according to the method specified in the individual monograph, perform the gas chromatography under the same operating conditions as for the preparation of the calibration curve, calculate the ratio of the peak area or peak height of the objective compound to that of the internal standard, and read the amount of the compound from the calibration curve.

In an individual monograph, generally one of the standard solutions with a concentration within the linear range of the calibration curve and a sample solution with a concentration close to that of the standard solution are prepared, and the chromatography is performed with these solutions under fixed conditions to determine the amount of the objective compound.

4.2. Absolute calibration curve method

Prepare standard solutions with several graded amounts of the authentic specimen, and inject accurately a fixed volume of these standard solutions. With the chromatogram obtained, prepare a calibration curve by plotting the peak areas or peak heights on the ordinate against the amount of the authentic specimen on the abscissa. The calibration curve is generally obtained as a straight line passing through the origin. Then, prepare a sample solution according to the method specified in the individual monograph, perform the gas chromatography under the same conditions as for the preparation of the calibration curve, measure the peak area or peak height of the objective compound, and read the amount of the compound from the calibration curve.

In an individual monograph, generally one of the standard solutions with a concentration within the linear range of the calibration curve and a sample solution with a concentration close to that of the standard solution are prepared, and the chromatography is performed with these solutions under a fixed condition to obtain the amount of the component. In this method, all procedures, such as the injection procedure, must be carried out under a strictly constant condition.

4.3. Standard addition method

Pipet a fixed volume of more than 4 sample solutions, add exactly the standard solution so that stepwise increasing amounts of the object compound are contained in the solutions except 1 sample solution, diluted exactly each solution with and without standard solution to a definite volume, and use each solution as the sample solution. Based on the chromatogram obtained by exact injection of a fixed volume of individual sample solutions, measure the peak area or peak height of individual sample solutions. Calculate the concentration of standard objective compound added into each sample solution, plot the amounts (concentration) of added standard object compound on the abscissa and the peak area or peak height on the ordinate on the graph, extend the calibration curve obtained by linking the plots, and determine the amount of object compound to be assayed from the distance between the origin and the intersecting point of the calibration curve with the abscissa. This method is available only in the case that the calibration curve is a straight line, and passes through the origin when the absolute calibration curve method is employed. In this method, all procedures must be carried out under a strictly constant condition.

5. Method for peak measuring

Generally, the following methods are used.

5.1. Peak height measuring method

(i) Peak height method: Measure the distance between the maximum of the peak and the intersecting point of a perpendicular line from the maximum of the peak to the horizontal axis of recording paper with a tangent linking the baselines on either side of the peak.

(ii) Automatic peak height method: Measure the signals from the detector as the peak height using a data processing...
5.2. Peak area measuring method
   (i) Width at half-height method: Multiply the peak width at the half-height by the peak height.
   (ii) Automatic integration method: Measure the signals from the detector as the peak area using a data processing system.

6. System suitability
   Refer to “System suitability” described under 2.01 Liquid Chromatography.

7. Point to consider in changing the operating conditions
   Among the operating conditions specified in the individual monograph, inside diameter and length of column, particle size of packing material, concentration or thickness of stationary phase, column temperature, temperature-rising rate, kind and flow rate of carrier gas, and split ratio may be modified within the ranges in which the gas chromatographic system used conforms to the requirements of system suitability. Headspace sample injection device and its operating conditions may be also modified, provided that they give equivalent or more accuracy and precision.

8. Terminology
   The definition of terms described under 2.01 Liquid Chromatography shall apply in 2.02 Gas Chromatography.

9. Note
   Avoid the use of authentic specimens, internal standards, reagents or solvents containing substances that may interfere with the determination.

2.03 Thin-layer Chromatography

Thin-layer Chromatography is a method to separate each ingredient by developing a mixture in a mobile phase, using a thin-layer made of a suitable stationary phase, and is applied for identification, purity test, etc. of substances.

1. Preparation of thin-layer plate
   Generally, proceed by the following method.
   A smooth and uniformly thick glass plate having a size of 50 mm × 200 mm or 200 mm × 200 mm is used for preparing a thin-layer plate. Using a suitable apparatus, apply a water suspension of powdered solid substance for the stationary phase, directed in the monograph, on one side of the glass plate to make a uniform layer of 0.2 to 0.3 mm in thickness. After air-drying, dry further by heating at a fixed temperature between 105°C and 120°C for 30 to 60 minutes. A suitable plastic plate may be used instead of the glass plate. Preserve the dried plate with protection from moisture.

2. Procedure
   Unless otherwise specified, proceed by the following method.
   Designate a line about 20 mm distant from the bottom of the thin-layer plate as the starting line, spot 2 to 6 mm in diameter the directed volumes of the sample solution or the standard solution in the monograph using micropipets at points on this line, separated by more than 10 mm, and air-dry. Unless otherwise specified, attach the filter paper along with the inside wall of the container, and wet the filter paper with the developing solvent. In the container, the developing solvent is placed up to about 10 mm in height from the bottom beforehand, seal the container closely, and allow it to stand for 1 hour at ordinary temperature. Place the plate in the container, avoiding contact with the inside wall, and seal the container. Develop it at ordinary temperature.
   When the solvent front has ascended to the distance directed in the monograph, remove the plate from the container. Immediately put a mark at the solvent front. After air-drying, observe the location, color, etc., of each spot by the method specified in the monograph. Calculate the Rf value by using the following equation:

\[ R_f = \frac{\text{distance from the starting line to the center of the spot}}{\text{distance from the starting line to the solvent front}} \]

2.04 Amino Acid Analysis of Proteins

Amino acid analysis of proteins refers to the methodology used to determine the amino acid composition or content of proteins, peptides, and other pharmaceutical preparations. Amino acid analysis can be used to quantify protein and peptides, to determine the identity of proteins or peptides based on their amino acid composition, to support protein and peptide structure analysis, to evaluate fragmentation strategies for peptide mapping, and to detect atypical amino acids that might be present in a protein or peptide. It is necessary to hydrolyze a protein/peptide to its individual amino acid constituents before amino acid analysis. Following protein/peptide hydrolysis, the amino acid analysis procedure can be the same as that practiced for free amino acids in other pharmaceutical preparations. The amino acid constituents of the test sample are typically derivatized for analysis.

1. Hydrolysis of Protein and Peptide
   Acid hydrolysis at 110°C for 24 hours using 6 mol/L hydrochloric acid containing phenol (Method 1) is the most common method for hydrolyzing protein and samples. The result should be analyzed carefully because several amino acids are chemically modified during the acid hydrolysis and thus not recovered quantitatively. Tryptophan is destroyed; serine and threonine are partially destroyed; methionine might undergo oxidation; and cysteine is typically recovered as cystine (but cystine recovery is usually poor because of partial destruction or reduction to cysteine). Peptide bonds involving isoleucine and valine are partially cleaved; and asparagine and glutamine are deamidated, resulting in aspartic acid and glutamic acid, respectively.
   The hydrolysis techniques, Methods 2 to 11, are used to address these concerns. Some of the hydrolysis techniques, Methods 4 to 11, may cause modifications of cysteine, methionine, asparagines and glutamine to other amino acids. Therefore, the benefits of using a given hydrolysis technique are weighed against the concerns with the technique and are tested adequately before employing a method other than acid hydrolysis by Method 1.

   (i) Method 1: Hydrolysis using hydrochloric acid containing phenol (liquid phase hydrolysis, vapor phase hy-
2.21 Nuclear Magnetic Resonance Spectroscopy / General Tests

A time-course study is often employed to analyze the starting concentration of amino acids that are partially destroyed or slow to cleave. An acceptable alternative to the time-course study is to subject an amino acid calibration standard to the same hydrolysis conditions as the test sample. This technique will allow the analyst to account for some residue destruction.

Microwave acid hydrolysis has been used and is rapid but requires special equipment as well as special precautions. Complete proteolysis, using a mixture of proteases, has been used but can be complicated, requires the proper controls, and is typically more applicable to peptides than proteins.

2. Methodologies of Amino Acid Analysis

The amino acid analysis techniques include the postcolumn derivatization for detection (Methods 1 to 2) after the separation of the free amino acids by ion-exchange chromatography and the precolumn derivatization of the free amino acids (Methods 2 to 7) followed by reversed-phase HPLC.

(ii) Method 2: Mercaptoethanesulfonic acid hydrolysis (vapor phase hydrolysis)

(iii) Method 3: Hydrolysis using hydrochloric acid containing thioglycolic acid (vapor phase hydrolysis)

(iv) Method 4: Hydrolysis by Method 1 or Method 2 after oxidation with performic acid

(v) Method 5: Hydrolysis using hydrochloric acid containing sodium azide (liquid phase hydrolysis)

(vi) Method 6: Hydrolysis using hydrochloric acid containing dimethylsulfoxide (vapor phase hydrolysis)

Cysteine-cystine oxidation

(vii) Method 7: Hydrolysis using hydrochloric acid after a vapor phase pyridylethylolation reaction

(viii) Method 8: Hydrochloric acid hydrolysis after a liquid phase pyridylethylolation reaction

(ix) Method 9: Hydrochloric acid hydrolysis after a liquid phase carboxymethylation reaction

Conversion of cysteine-cystine to mixed disulfide

(x) Method 10: Hydrochloric acid hydrolysis after a reaction with dithiodiglycolic acid or dithiodipropionic acid

Derivatization of asparagine and glutamine

(xi) Method 11: Hydrochloric acid hydrolysis after reaction with bis(1,1-trifluorooctoxy)iodobenzene

A time-course study is often employed to analyze the starting concentration of amino acids that are partially destroyed or slow to cleave. An acceptable alternative to the time-course study is to subject an amino acid calibration standard to the same hydrolysis conditions as the test sample. This technique will allow the analyst to account for some residue destruction.

Microwave acid hydrolysis has been used and is rapid but requires special equipment as well as special precautions. Complete proteolysis, using a mixture of proteases, has been used but can be complicated, requires the proper controls, and is typically more applicable to peptides than proteins.

2. Methodologies of Amino Acid Analysis

The amino acid analysis techniques include the postcolumn derivatization for detection (Methods 1 to 2) after the separation of the free amino acids by ion-exchange chromatography and the precolumn derivatization of the free amino acids (Methods 2 to 7) followed by reversed-phase HPLC.

(i) Method 1: Ninhydrin

(ii) Method 2: o-Phthalaldehyde (OPA)

(iii) Method 3: Phenylisothiocyanate (PITC)

(iv) Method 4: 6-Aminoquinolyl-N-hydroxysuccinimidyl carbamate (AQC)

(v) Method 5: (Dimethylamino)azobenzenesulfonyl chloride (DABS-Cl)

(vi) Method 6: 9-Fluorenylmethyl chloroformate (FMOC-Cl)

(vii) Method 7: 7-Fluoro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-F)

Among these methods, ion-exchange chromatography with postcolumn ninhydrin derivertization is one of the most common methods employed for quantitative amino acid analysis. The choice of any one technique often depends on the sensitivity required from the assay. Instruments and reagents for these procedures are available commercially. Furthermore, many modifications of these methodologies exist with different reagent preparations, reaction procedures, chromatographic systems, etc. Specific parameters may vary according to the exact equipment and procedure used.

Spectroscopic Methods

2.21 Nuclear Magnetic Resonance Spectroscopy

Nuclear Magnetic Resonance (NMR) Spectroscopy is based on the phenomenon that specific radio frequency radiation is absorbed by magnetic nuclei in a sample placed in a magnetic field; target nuclei are 1H, 13C, 15N, 19F, 31P, etc. These nuclei have intrinsic spin angular momentum, of which the magnitude is given by \( I (I + 1)/2 \), where \( I \) is the spin quantum number and is integral or half-integral (\( I = 1/2 \) for 1H and 13C). When the magnetic nuclei are placed in a magnetic field, they are oriented in \( 2I + 1 \) possible orientations corresponding to \( 2I + 1 \) equally spaced energy levels (two energy levels for 1H and 13C). The transition between two successive quantized energy levels corresponding to adjacent orientations can be induced by electromagnetic radiation with a suitable frequency. The precise relation between the field strength and the resonant frequency is given by

\[
v = \frac{v_R H_0}{2\pi} \]

where \( H_0 \) is the strength of the applied external magnetic field and \( v \) is the gyromagnetic ratio, a constant characterizing a particular isotope. The absorption of radiation (NMR signal) can occur only when the irradiating radio frequency satisfies the resonance condition. Since the absorption coefficient (the transition probability) does not depend on the environment in which the nuclei are located, the intensity is basically proportional to the number of nuclei. The excess spins shifted to the higher energy levels by the transition process return to the thermal equilibrium state at various rates determined by a characteristic time constant (known as the relaxation time).

A nucleus is shielded from the applied magnetic field by the electrons belonging to its own atom and to the molecule. Therefore nuclei in different environments are shielded to different extents and resonate at different frequencies. The difference in resonance frequencies is defined as chemical shift (\( \delta \)), which is independent of the strength of the magnetic field, and is given by

\[
\delta = \frac{v_o - v_R}{v_R} + \delta_R
\]

where,

- \( v_o \): The resonance frequency of the observed signal,
- \( v_R \): The resonance frequency of the reference signal,
- \( \delta_R \): The chemical shift of the reference signal (in the case of the value not being 0).

The chemical shifts are normally expressed in ppm, a
dimensionless unit, by assuming the chemical shift of the reference compound as 0 ppm. When the chemical shift of the reference compound is not assumed to be 0 ppm, chemical shifts of samples are corrected accordingly.

In addition to the shielding due to electrons, the nucleus is subjected to effects due to the spin orientations of other magnetic nuclei through chemical bonds, resulting in an additional splitting of the signal. The spacing between two adjacent components of the signal is known as the spin-spin coupling constant ($J$). Coupling constants are measured in hertz and are independent of the strength of the external magnetic field. The increased number of interacting nuclei will make the multiplet pattern more complex.

From the NMR spectrum the following four parameters can be obtained: chemical shift, spin-spin coupling constant, resonance intensity (intensities of $^1H$ are proportional to the number of nuclei and those of $^{13}C$ and others are susceptible to the nuclear Overhauser effect (NOE) and relaxation) and relaxation time. These parameters are useful for structural determination, identification and quantitative analysis of molecules. Spin decoupling, NOE, and two-dimensional NMR techniques are also available for structural analysis.

1. **Spectrometer**
   
   There are two types of spectrometers.

1.1. **Fourier transform NMR (FT-NMR) spectrometers** (Fig. 2.21-1)

   Target nuclei are simultaneously excited in all frequency range of the nuclei by means of an intense radio frequency pulse. The FID (free induction decay) after the pulse is detected, which is a time domain signal, is converted to a frequency domain spectrum by Fourier transformation. Number of data points suitable for the spectral range, flip angle, acquisition time, delay time and number of scans should be set appropriately.

   Recently FT-NMR is commonly used because of its high sensitivity and various advanced applications.

1.2. **Continuous wave NMR (CW-NMR) spectrometers** (Fig. 2.21-2)

   In the case of the CW method, a spectrum is obtained by sweeping the radio frequency or magnetic field continuously over the frequency range of the nuclei being observed.

2. **Measurement**

   Prior to measurements, the sensitivity and resolution of the instrument must be adjusted to the optimum levels using a standard sample (ethylbenzene, 1,2-dichlorobenzene or acetaldehyde) dissolved in an appropriate NMR solvent.

   The sample dissolved in a suitable solvent is transferred into an NMR tube. The reference compound can be added directly to the sample solution (internal reference), or a sealed capillary tube containing the reference compound can be inserted into the NMR tube (external reference). The sample solutions should be completely homogeneous. In particular, solid contaminants should be removed in order to obtain good spectra. Various deuterated NMR solvents are commonly used for NMR measurement and the following points should be considered in selecting an appropriate solvent: (i) The solvent signals do not overlap with the sample signals. (ii) The sample must be soluble in the solvent selected. (iii) The solvent does not react with the sample. Furthermore, it should be noted that chemical shifts can depend upon the solvent employed, sample concentration and deuterium ion concentration, and that viscous solutions usually give rather broad, poorly resolved spectra.

   For the reference standards use the reagents for nuclear magnetic resonance spectroscopy. For $^1H$ and $^{13}C$ spectra, tetramethylsilane (TMS) is usually used as the reference compound for samples dissolved in organic solvents. For samples dissolved in deuterium oxide, sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) or sodium 3-(trimethylsilyl)propionate (TSP) is used. For other nuclei, nitromethane, trichlorofluoromethane and phosphoric acid are used as reference compounds for $^{15}N$, $^{19}F$ and $^{31}P$, respectively. Furthermore, chemical shifts of residual protons in deuterated solvents and $^{13}C$ in the solvent instead of a reference compound can be used for $^1H$ and $^{13}C$ NMR.

3. **Record of apparatus and measurement conditions**

   Type of instrument, frequency, solvent, temperature, sample concentration, reference compound, experimental technique, etc. should be recorded to allow appropriate comparison of spectra, because NMR spectra depend on the measurement conditions.

4. **Identification**

   The sample solution is prepared and tested by the method directed in each monograph. Usually in the case of $^1H$ NMR, the sample is identified by the following method.

4.1. **Identification by the use of chemical shift, multiplicity and relative intensity**

   When chemical shifts, multiplicities and relative intensities...
of signals are defined, the sample can be identified as being the same substance when all chemical shifts, multiplicities and relative intensities are the same as those prescribed.

4.2. Identification by the use of a Reference Standard

Measurement conditions should be the same as those used in the case of the Reference Standard. When the spectra of a sample and the Reference Standard exhibit the same multiplicities and relative intensities of signal at the same chemical shifts, the sample can be identified as being the same substance as the Reference Standard.

5. Experimental techniques of \( ^1H \) and \( ^{13}C \) NMR spectroscopy

NMR spectroscopy includes one-, two- and multi-dimensional techniques, which are used for various purposes.

Spin decoupling, and NOE are available in one-dimensional \( ^1H \) spectroscopy. Spin decoupling can assign coupling correlations. As NOE can observe correlations among spatially proximate protons, the configuration and the conformation can be analyzed.

Broadband decoupling, INEPT and DEPT are usually applied in one-dimensional \( ^{13}C \) spectroscopy. The broadband decoupling technique simplifies a spectrum and achieves enhancement of sensitivity. INEPT (insensitive nuclei enhanced by polarization transfer) and DEPT (distortionless enhancement of polarization transfer) enhance the sensitivity of \( ^{13}C \) by means of polarization transfer from directly bonded \( ^1H \) with a large magnetic moment. They can be applied to identify primary, secondary, tertiary or quarternary carbon.

Two-dimensional spectroscopy can observe all correlation peaks between nuclei through spin-spin coupling or NOE in a single experiment, and there are many techniques for homonuclear and heteronuclear measurements. Representative techniques are described below.

COSY (2D correlation spectroscopy), HOHAHA (homonuclear Hartmann-Hahn spectroscopy) or TOCSY (total correlation spectroscopy): Correlation between protons through scalar spin-spin coupling is obtained and intramolecular connectivities of hydrogen atoms are revealed.

NOESY (2D nuclear Overhauser enhancement and exchange spectroscopy): NOE is measured by a two-dimensional technique. Approximate distances between spatially proximate hydrogen atoms are obtained to analyze the three-dimensional structure.

INADEQUATE (incredible natural abundance double quantum transfer experiment): Although this technique is insensitive because it involves double quantum transfer by \( ^{13}C-^{13}C \) scalar coupling in a sample with natural isotopic abundance, the connectivities of all neighboring \( ^{13}C \) nuclei can be obtained to analyze the carbon skeleton.

HMQC (heteronuclear multiple quantum coherence): This technique observes correlations between \( ^1H \) and \( ^{13}C \) with direct spin-spin coupling using \( ^1H \) detection and reveals intramolecular chemical bonds between hydrogen and carbon atoms.

HMBC (heteronuclear multiple bond connectivity): This technique observes correlations between \( ^1H \) and \( ^{13}C \) with long range spin-spin coupling using \( ^1H \) detection and reveals intramolecular connectivities of hydrogen and carbon atoms.

There are many other techniques such as DQF-COSY (double quantum filtered COSY) and HSQC (heteronuclear single quantum coherence). Furthermore, multidimensional NMR techniques are used to analyze macromolecules.

2.22 Fluorometry

Fluorometry is a method to measure the intensity of fluorescence emitted from a solution of fluorescent substance irradiated with an exciting light in a certain wavelength range. This method is also applied to the phosphorescent substances.

Fluorescence intensity \( F \) in a dilute solution is proportional to the concentration \( c \) in mol per liter of the solution and the pathlength \( l \) of light through the solution in centimeter.

\[
F = kI_0\phi cl
\]

\( k: \) Constant
\( I_0: \) Intensity of exciting light
\( \phi: \) Quantum yield of fluorescence or phosphorescence

\[
\phi = \frac{\text{number of quanta emitted as fluorescence or phosphorescence}}{\text{number of quanta absorbed}}
\]

\( \varepsilon: \) Molar extinction coefficient of the substance at the excitation wavelength

1. Apparatus

Spectrofluorometer is usually used. Generally, a xenon lamp, laser, an alkaline halide lamp, etc. which provide stable exciting light are used as the light source. Usually, a non-fluorescent quartz cell (1 cm × 1 cm) with four transparent sides is used as the container for sample solution.

2. Procedure

Excitation spectrum is obtained by measuring fluorescence intensities of sample solution with varying excitation wavelengths at a fixed emission wavelength (in the vicinity of the fluorescence maximum) and drawing a curve showing the relationship between the excitation wavelength and the fluorescence intensity. Fluorescence spectrum is obtained by measuring fluorescence intensities of sample solution with varying emission wavelengths at a fixed excitation wavelength (in the vicinity of the excitation maximum) and drawing the same curve as described for the excitation spectrum. If necessary, the spectra are corrected with regard to the optical characteristics of the apparatus.

The fluorescence intensity is usually measured at the excitation and the emission wavelengths in the vicinity of excitation and emission maxima of the fluorescent substance. The fluorescence intensity is expressed as a value relative to that of a standard solution, because it is readily affected even by a slight change in the condition for the measurement.

Unless otherwise specified, the instrument is operated as follows with standard, sample, and reference solutions prepared as directed in the monograph: Fix the excitation and fluorescence wavelength scales at the designated positions, adjust the dark current to zero, put the quartz cell containing the standard solution in the light path, and adjust the instrument so that the standard solution shows the fluorescence intensity of 60% to 80% of full scale. Then perform the measurements with cells containing the sample solution and the control solution, and read the fluorescence intensity as % under the same condition. Set the width of the wavelength properly unless otherwise specified.
3. Note
The fluorescence intensity is readily affected by the concentration, temperature and pH of the solution, and nature and purity of solvents or reagents used.

2.23 Atomic Absorption Spectrophotometry

Atomic Absorption Spectrophotometry is a method to determine the amount or the concentration of an element in a sample specimen being examined, by utilizing the phenomenon that atoms being in the ground state absorb the light of specific wavelength, characteristic of the respective atom, when the light passes through an atomic vapor layer of the element to be determined.

1. Apparatus
Usually, the apparatus consists of a light source, a sample atomizer, a spectroscope, a photometer and a recording system. Some are equipped with a background compensation system. As a light source, usually a hollow cathode lamp specified for each element is used and sometimes a discharge lamp is also used. There are three types of sample atomizer: the flame type, the electrothermal type, and the cold-vapor type. The first one is composed of a burner and a gas-flow regulator, the second one is composed of an electric furnace and a power source, and the third one is composed of a mercury generator and an absorption cell. The third one is further classified into two subtypes, which differ in the atomizing method for mercury containing-compounds: one utilizes chemical reduction-vaporization and the other utilizes a thermal reduction-vaporization method.

For the selection of an appropriate analytical wavelength in a spectroscope, a grating for light diffraction or an interference filter can be used. A recording system is composed of a display and a recording device. A background compensation system is employed for the correction of atmospheric effects on the measuring system. Several principles can be utilized for background compensation, using continuous spectrum sources, the Zeeman splitted spectrum, the non-resonance spectrum, or self-inversion phenomena.

Another special options such as a hydride generator and a heating cell, can also be used for analyzing such as selenium. As a hydride generator, a batch method and/or a continuous flow method can be applied. While as a heating cell, there are two kinds of cell: one for heating by flame and the other for heating by electric furnace.

2. Procedure

Unless otherwise specified, proceed by any of the following methods.

2.1. Flame type
Fit the specific light source to the lamp housing and switch on the instrument. After lighting the lamp and selecting the analytical wavelength specified in the monograph, set an appropriate electric current and slit-width. Next, a mixture of a combustible gas and a supporting gas is ignited and the gas flow rate and/or pressure should be adjusted to optimum conditions. The zero adjustment of the detecting system must be done through nebulizing the blank solvent into the flame. After setting up the measuring system, the sample solution prepared by the specified procedure is introduced into the flame and the light absorption at the characteristic wavelength of the element to be determined is measured.

2.2. Electrothermal type
Fit the specific light source to the lamp housing and switch on the instrument. After lighting the lamp and selecting the analytical wavelength specified in the monograph, set an appropriate electric current and slit-width. Further, set an electric furnace to the appropriate temperature, electric current, and heating program, as directed separately in the monograph. When a suitable amount of sample is injected into the heated furnace with an appropriate stream of inert gas, the sample is dried and ashed, simultaneously with atomization of the metallic compound included in the specimen. The atomic absorption specified is observed and the intensity of absorption is measured. Details of the sample preparation method are provided separately in the monograph.

2.3. Cold vapor type
Fit the mercury lamp to the lamp housing and switch on the instrument. After lighting the lamp and selecting the analytical wavelength specified in the monograph, set an appropriate electric current and a slit-width. In the chemical atomization-vaporization method, a mercury containing compound in the sample solution, prepared by the specified procedure, is chemically reduced to metallic mercury by adding a proper reducing reagent to the closed vessel and the generated mercury is vaporized and introduced into the absorption cell with a flow of inert gas. In the thermal atomization-vaporization method, the sample specimen on a quartz dish is heated electrically and the generated atomic mercury is vaporized and introduced into the absorption cell with a flow of inert gas. Thus, in both methods, the generated atomic mercury is carried into the absorption cell as cold vapor and the intensity of the characteristic atomic absorption of mercury is measured.

3. Determination

Usually, proceed by any of the following methods. In the determination, the possibility of interference for various reasons and the background effect must be considered and avoided if possible.

3.1. Calibration curve method
Prepare standard solutions at more than 3 concentration levels, measure the specific absorption due to these standard solutions, and prepare the calibration curve of the atomic absorption against the concentration. Then measure the atomic absorption due to the sample specimen, in which the concentration of the element to be determined should be adjusted to be within the concentration range of the standard solutions, and determine the amount or the concentration of the element to be examined using the calibration curve.

3.2. Standard addition method
To equal volumes of more than 3 sample solutions, prepared as directed in the monograph, add a measured quantity of the standard solutions to produce a series of solutions containing increasing amounts of the element to be examined, and further add a solvent to make up a constant volume. Measure the atomic absorption for the respective solutions, and plot the obtained values on a graph with the added amount or the concentration on the abscissa and the absorbance on the ordinate. Extrapolate the linear plot obtained by linking the data points, and determine the amount or the concentration of the element to be examined from the
distance between the origin and the point where the plot intersects with the abscissa. This method is available only when the calibration curve obtained by Method (1) is confirmed to be linear and to pass through the origin.

3.3. Internal standard method

Prepare a series of standard solutions of the element to be determined, each containing a definite amount of the internal standard element directed in the monograph. For these standard solutions, measure the atomic absorption due to the standard element and the internal standard element separately at the respective wavelengths under the same operating conditions, and obtain the ratio of absorbance by the standard element to that by the internal standard element. Prepare a calibration curve for the element to be determined, with the amount or the concentration of the standard element on the abscissa and the above-mentioned ratio of the absorbance on the ordinate. Then prepare sample solutions, adding the same amount of the internal standard element as contained in the standard solutions. Measure the ratio of the absorbance due to the element to be determined to that due to the internal standard element under the same conditions as employed for preparing the calibration curve, and determine the amount or the concentration of the element being examined by using the calibration curve.

4. Note

Reagents, test solutions, and gases used in this test should not interfere in any process of the measurement.

2.24 Ultraviolet-visible Spectrophotometry

Ultraviolet-visible Spectrophotometry is a method to measure the degree of absorption of light between the wavelengths of 200 nm and 800 nm by substances for the tests of their identity and purity, and for assay. When an atomic absorption spectrophotometer is used for these purposes, proceed as directed under Atomic Absorption Spectrophotometry 2.25. When monochromatic light passes through a substance in the solution, the ratio of transmitted light intensity \( I \) to incident light intensity \( I_0 \) is called transmittance \( T \); transmittance expressed in the percentage is called percent transmittance. The absorbance \( A \) is given by

\[
A = \log \frac{I_0}{I} = k c l
\]

where \( k \) is the molar absorption coefficient, \( c \) is the concentration of the element in molar, and \( l \) is the path length in cm. The difference between absorbance and wavelength. From the absorption spectrum, it is possible to determine the wavelength of maximum absorption \( \lambda_{\text{max}} \) and that of minimum absorption \( \lambda_{\text{min}} \).

The absorption spectrum of a substance in the solution is characteristic, depending on its chemical structure. Therefore, it is possible to identify a substance by comparing the spectrum of a sample within the specified wavelength range with the Reference Spectrum or the spectrum of Reference Standard, by determining the wavelengths of maximum absorption, or by measuring the ratio of absorbances at two specified wavelengths. For the purpose of assay, the absorbance by a sample solution with a certain concentration is measured at the wavelength of the maximum absorption \( \lambda_{\text{max}} \) and compared it with the absorbance of a standard solution with a certain concentration.

1. Apparatus and adjustment

A spectrophotometer or a photoelectric photometer is used for the measurement of absorbance.

After adjusting the spectrophotometer or photoelectric photometer based on the operation manual of the apparatus, it should be confirmed that the wavelength and the transmission rate meet the specifications of the tests described below.

The calibration of wavelength should be carried out as follows. Using an optical filter for wavelength calibration, measure the transmission rate in the vicinity of the standard wavelength value shown in the test results form, under the test conditions given in the test results form attached to each of the filters. When performing a test to determine the wavelength which shows minimal transmission rate, the difference between the measured wavelength and the standard wavelength value should be within ± 0.5 nm. When the measurement is repeated three times, each value obtained should be within the mean ± 0.2 nm. It is also possible to carry out the test using a low-pressure mercury lamp at bright line wavelengths of 253.65 nm, 365.02 nm, 435.84 nm and 546.07 nm, or a deuterium discharge lamp at bright line wavelengths of 486.00 nm and 656.10 nm. In the case of these tests, the difference between the measured wavelength and the wavelength of the bright line should be within ± 0.3 nm. When the measurement is repeated three times, each value obtained should be within the mean ± 0.2 nm.

The calibration of transmission rate or absorbance should be carried out as follows. Using an optical filter for transmission rate calibration, determine the transmission rate at the standard wavelength value under the test conditions given in the test results form attached to each of the filters. The difference between the measured transmission rate and the standard transmission rate value should be within the range of from 1% larger of the upper limit to 1% smaller of the lower limit for the relative accuracy shown in the test results form. When the measurement is repeated three times, each absorbance obtained (or calculated from the transmission rate) should be within the mean ± 0.002 when the absorbance is not more than 0.500, and within the mean ± 0.004 when the absorbance is more than 0.500. In addition, it will be desirable to confirm the linearity of transmission rate at the same wavelength using several optical filters for calibration of transmission rate with different transmission rates.

2. Procedure

After adjusting the apparatus as directed in the Apparatus and adjustment, select and set the light source, detector,
mode of measurement, measuring wavelength or wavelength range, spectrum width and scanning speed.

Subsequently, allow the apparatus to stand for a certain time to confirm its stability. Then, usually adjust the apparatus so that the transmittance is 0% at measuring wavelength or over measuring wavelength range after shutting the sample side of light path. Then open the shutter and adjust the transmittance to 100% (the absorbance is zero). Adjusting the transmittance to 100% is usually done by putting cells containing the control solution in both light paths. For the control solution, unless otherwise specified, blank solvent is used.

Then perform the measurement with the cell containing the sample solution, and read the absorbance at measuring wavelength, or measure the spectrum over measuring wavelength range. Unless otherwise specified, a cell with a path length of 1 cm, made of quartz for ultraviolet range and of quartz or glass for visible range, is used. Special consideration is needed with the absorption of solvents in the ultraviolet range; use a solvent which does not disturb accurate measurement.

3. Specific absorbance

In the Japanese Pharmacopoeia, the absorbance, calculated on the basis that l is 1 cm and c (concentration of a medicament) is 1 w/v%, is called specific absorbance, and is expressed as $E_{1\text{cm}}^{1\%}$.

$$E_{1\text{cm}}^{1\%} = \frac{A}{c \times l}$$

l: Length of the layer of the solution (cm)
A: Absorbance value
c: Concentration of the sample in the solution (w/v%)

The description of, for example, “$E_{1\text{cm}}^{1\%}$ (241 nm): 500 – 530 (after drying, 2 mg, methanol, 200 mL)” in the monograph, indicates that observed $E_{1\text{cm}}^{1\%}$ value is between 500 and 530, when the test is performed in the following manner: The sample is dried under the conditions specified in the Test for Loss on Drying, and about 2 mg of the sample is weighed accurately with a microbalance, and dissolved in methanol to make exactly 200 mL, then the absorbance of the solution is measured as directed in the Procedure at a wavelength of 241 nm using a cell with a path length of 1 cm.

4. Identification

Prepare the sample solution as directed in the monograph, and test as directed in the Procedure. Usually, the test is performed by a single method or in a combination of a few methods in the following methods using the absorbance or absorption spectrum obtained from the sample solution. Subtle differences in the absorption spectrum arising from differences in the apparatus used may be neglected.

4.1. Identification using Reference Spectrum

When the absorption spectrum obtained from the sample solution exhibits similar intensities of absorption at the same wavelengths as those of the Reference Spectrum, the identity of the sample and the reference may be confirmed. In this case, the range of the wavelength to be compared is the range shown on the Reference Spectrum.

Reference spectrum: Reference spectra are specified under the Ultraviolet-visual Reference Spectra, which are used as the reference for the test of identification specified in the monograph.

4.2. Identification using Reference Standard

When the absorption spectrum obtained from the sample solution exhibits similar intensities of absorption at the same wavelengths as those of the spectrum obtained from the Reference Standard, the identity of the sample and the reference may be confirmed. In this case, the range of the wavelength to be compared is the range shown on the Reference Spectrum. When the relevant Reference Spectrum is not available, the range is that specified in the monograph.

4.3. Identification using absorption wavelength

When maximum absorption wavelengths of the spectrum obtained from the sample solution match the wavelengths specified in the monograph, the identity of the substance may be confirmed. In this case, the range of the wavelength to be compared is the range shown on the Reference Spectrum.

4.4. Identification using the ratio of the absorbances obtained at two or more wavelengths

When the ratios of absorbances at the specified wavelengths in the spectrum obtained from the sample solution meet the specifications in the monograph, the identity of the substance may be confirmed.

5. Assay

Prepare the control solution, the sample solution and the standard solution as directed in the monograph, measure the absorbances of the sample solution and the standard solution according to the method described in the Procedure, and determine the amount of the substance to be assayed in the sample by comparing the absorbances.

2.25 Infrared Spectrophotometry

Infrared Spectrophotometry is a method of measurement of the extent, at various wave numbers, of absorption of infrared radiation when it passes through a layer of a substance. In the graphic representation of infrared spectra, the plot usually shows units of wave numbers as the abscissa and units of transmittance or absorbance as the ordinate. Wave number and transmittance or absorbance at each absorption maximum may be read graphically on an absorption spectrum and/or obtained by a data-processor. Since the wave number and the respective intensity of an absorption maximum depend on the chemical structure of a substance, this measurement can be used to identify or determine a substance.

1. Instrument and adjustment

Several models of dispersive infrared spectrophotometers or Fourier-transform infrared spectrophotometers are available.

The instruments, adjusted according to the instruction manual of each individual instrument, should comply with the following test for resolving power, transmittance reproducibility and wave number reproducibility. When the spectrum of a polystyrene film about 0.04 mm thick is recorded, the depth of the trough from the maximum absorption at about 2850 cm$^{-1}$ to the minimum at about 2870 cm$^{-1}$ should not be less than 18% transmittance and that from the maximum at about 1583 cm$^{-1}$ to the minimum at about 1589 cm$^{-1}$ should be not less than 12% transmittance.

The wave number (cm$^{-1}$) scale is usually calibrated by the
use of several characteristic absorption wave numbers (cm\(^{-1}\)) of a polystyrene film shown below. The number in parentheses indicates the permissible range.

\[
\begin{align*}
3060.0 \pm 1.5 & \quad 2849.5 \pm 1.5 & \quad 1942.9 \pm 1.5 \\
1601.2 \pm 1.0 & \quad 1583.0 \pm 1.0 & \quad 1154.5 \pm 1.0 \\
1028.3 \pm 1.0 & \\
\end{align*}
\]

When the dispersive infrared spectrophotometer is used, the permissible range of the absorption wave numbers at 1601.2 cm\(^{-1}\) and at 1028.3 cm\(^{-1}\) should be both within ± 2.0 cm\(^{-1}\).

As the repeatability of transmittance and wave number, the difference of transmittance should be within 0.5% when the spectrum of a polystyrene film is measured twice at several wave numbers from 3000 to 1000 cm\(^{-1}\), and the difference of wave number should be within 5 cm\(^{-1}\) at about 3000 cm\(^{-1}\) and within 1 cm\(^{-1}\) at about 1000 cm\(^{-1}\).

2. Preparation of samples and measurement

Unless otherwise specified, when it is directed to perform the test "after drying the sample", use a sample dried under the conditions specified in the monograph. Prepare the specimen for the measurement according to one of the following procedures so that the transmittance of most of the absorption bands is in the range of 5% to 80%. Single crystals of sodium chloride, potassium bromide, etc. are available for the optical plate. Generally, the reference cell or material is placed in the reference beam for double-beam instruments, while for single-beam instruments, it is placed in the same optical path in place of the specimen and measured separately under the same operating conditions. The composition and preparation of the reference depend on the sample preparation methods, and sometimes the background absorption of the atmosphere can be utilized.

Unless otherwise specified in the monograph, the spectrum is usually recorded between 4000 cm\(^{-1}\) and 400 cm\(^{-1}\). The spectrum should be scanned using the same instrumental conditions as were used to ensure compliance with the requirements for the resolving power and for the precision of wave number scale and of wave numbers.

2.1. Potassium bromide disk or potassium chloride disk method

Powder 1 to 2 mg of a solid sample in an agate mortar, triturate rapidly with 0.10 to 0.20 g of potassium bromide or potassium chloride for infrared spectrophotometry with precautions against moisture absorption, and compress the mixture with a press in a suitable die (disk-forming container) to make the sample disk. If necessary to obtain a transparent disk, press the mixture under vacuum in a die with pressure applied to the die of 50 to 100 kN per cm\(^{2}\) for 5 to 8 minutes. Prepare a potassium bromide reference disk or a potassium chloride reference disk in the same manner as the sample disk.

2.2. Solution method

Place the sample solution prepared by the method directed in each monograph in a fixed cell for liquid, and usually measure the spectrum against the reference solvent used for preparing the sample solution. The solvent used in this method should not show any interaction or chemical reaction with the specimen to be examined and should not damage the optical plate. The thickness of the fixed cell is usually 0.1 mm or 0.5 mm.

2.3. Paste method

Powder 5 to 10 mg of a solid specimen in an agate mortar, and, unless otherwise specified, triturate the specimen with 1 to 2 drops of liquid paraffin to give a homogeneous paste. After spreading the paste to make a thin film in the center of an optical plate, place the plate upon another optical plate with precautions against intrusion of air, bubbles in the film, and examine its absorption spectrum.

2.4. Liquid film method

Examine 1 to 2 drops of a liquid specimen as a thin film held between two optical plates. When the absorption intensity is not sufficient, place spacers of aluminum foil, etc., between the two optical plates to make a thicker liquid film.

2.5. Film method

Examine a thin film just as it is or a prepared thin film as directed in each monograph.

2.6. Gas sampling method

Put a sample gas in a gas cell previously evacuated under the pressure directed in the monograph, and examine its absorption spectrum. The path length of the gas cell is usually 5 cm or 10 cm, but, if necessary, may exceed 1 m.

2.7. ATR method

Place a specimen in close contact with an attenuated total reflectance (ATR) prism, and examine its reflectance spectrum.

2.8. Diffuse reflectance method

Powder 1 to 3 mg of a solid specimen into a fine powder of not more than about 50 \(\mu\)m particle size in an agate mortar, and triturate rapidly with 0.05 to 0.10 g of potassium bromide or potassium chloride for infrared spectrophotometry with precautions against moisture absorption. Place the mixture in a sample cup, and examine its reflectance spectrum.

3. Identification

When the spectrum of a specimen and the Reference Spectrum of the substance expected to be found or the spectrum of the Reference Standard exhibit similar intensities of absorption at the same wave numbers, the specimen can be identified as being the substance expected to be found. Furthermore, when several specific absorption wave numbers are specified in the monograph, the identification of a specimen with the substance expected to be found can be confirmed by the appearance of absorption bands at the specified wave numbers.

3.1. Identification by the use of a Reference Standard

When the spectra of a specimen and the Reference Standard exhibit similar intensities of absorption at the same wave numbers, the specimen can be identified as being the same substance as the Reference Standard. When a sample treatment method for a solid specimen is indicated in the monograph in the case of nonconformity of the spectrum with that of the Reference Standard, treat the specimen being examined and the Reference Standard in the same manner as directed in the monograph, then repeat the measurement.

3.2. Identification by the use of a Reference Spectrum

When the spectra of a specimen and the Reference Spectrum exhibit similar intensities of absorption at the same wave numbers, the specimen can be identified as being the same substance associated with the Reference Spectrum. When a sample treatment method for a solid specimen is indicated in the monograph in the case of nonconformity of the spectrum with the Reference Spectrum, treat the speci-
men being examined as directed in the monograph, then repeat the measurement.

Infrared Reference Spectra, in the range between 4000 \( \text{cm}^{-1} \) and 400 \( \text{cm}^{-1} \), are shown at the end of this book for the monographs requiring the identification test by Infrared Spectrophotometry, except for monographs in which "Identification by absorption wave number" is specified.

3.3. Identification by the use of absorption wave number

When several specific absorption wave numbers of the substance being examined are specified in the monograph, a specimen can be identified as being the same substance as the expected substance by confirmation of clear appearance of the absorption bands at all the specified wave numbers.

Other Physical Methods

2.41 Loss on Drying Test

Loss on Drying Test is a method to measure the loss in mass of the sample, when dried under the conditions specified in each monograph. This method is applied to determine the amount of water, all or a part of water of crystallization, or volatile matter in the sample, which is removed during the drying.

The description, for example, "not more than 1.0% (1 g, 105°C, 4 hours)" in a monograph, indicates that the loss in mass is not more than 10 mg per 1 g of the substance in the test in which about 1 g of the substance is accurately weighed and dried at 105°C for 4 hours, and "not more than 0.5% (1 g, in vacuum, phosphorus (V) oxide, 4 hours)," indicates that the loss in mass is not more than 5 mg per 1 g of the substance in the test in which about 1 g of the substance is accurately weighed, transferred into a desiccator (phosphorus (V) oxide), and dried in vacuum for 4 hours.

1. Procedure

Weigh accurately a weighing bottle that has been dried for 30 minutes according to the method specified in the monograph. Take the sample within the range of ±10% of the amount directed in the monograph, transfer into the weighing bottle, and, unless otherwise specified, spread the sample so that the layer is not thicker than 5 mm, then weigh it accurately. Place the loaded bottle in a drying chamber, and dry under the conditions specified in the monograph. When the size of the sample is large, convert it to small particles having a size not larger than 2 mm in diameter by quick crushing, and use the crushed sample for the test. After drying, remove from the drying chamber, and reweigh accurately. When the sample is dried by heating, the temperature is within the range of ±2°C of that directed in the monograph, and, after drying the bottle, the sample is allowed to cool in a desiccator (silica gel) before weighing.

If the sample melts at a temperature lower than that specified in the monograph, expose the sample for 1 to 2 hours to a temperature between 5°C and 10°C below the melting temperature, dry under the conditions specified in the monograph. Use a desiccant specified in the monograph, and renew frequently.

2.42 Congealing Point Determination

The congealing point is the temperature measured by the following method.

1. Apparatus

Use the apparatus illustrated in Fig. 2.42-1.

2. Procedure

Transfer the sample into sample container B up to the marked line C. When the sample is solid, melt the sample by heating to a temperature not higher than 20°C above the expected congealing point, and transfer to B. Fill the glass or plastic bath D with water at a temperature about 5°C below the expected congealing point. When the sample is liquid at room temperature, fill bath D with water at a temperature between 10°C and 15°C lower than the expected congealing point.
Insert the sample container B containing the sample into cylinder A. Adjust the immersion line H of thermometer F to the same level of the meniscus of the sample. After cooling the sample to about 5°C above the expected congealing point, move vertically the stirrer E at the rate of about 60 to 80 strokes per minute, and observe the thermometer readings at 30-second intervals. The temperature falls gradually. Discontinue stirring, when an appreciable amount of crystals has formed and the temperature is constant or has begun to rise. Usually, read the maximum temperature (reading of F), that is constant for a while after a rise of temperature. If no rise of temperature occurs, read the temperature that is constant for a while. The average of not less than four consecutive readings that lie within a range of 0.2°C constitutes the congealing point.

3. Note
If a state of super cooling is anticipated, rub the inner wall of bath B or put a small fragment of the solid sample into bath B for promoting the congealment, when the temperature approaches near the expected congealing point.

2.43 Loss on Ignition Test

Loss on Ignition Test is a method to measure the loss in mass when the sample is ignited under the conditions specified in each monograph. This method is usually applied to inorganic drugs which lose a part of the components or impurities during ignition.

The description, for example, “40.0 – 52.0% (1 g, 450 – 550°C, 3 hours)” in a monograph, indicates that the loss in mass is 400 to 520 mg per g of the substance in the test in which about 1 g of the substance is weighed accurately and ignited between 450°C and 550°C for 3 hours.

1. Procedure

Previously ignite a crucible or a dish of platinum, quartz or porcelain to constant mass, at the temperature directed in the monograph, and weigh accurately after cooling.

Take the sample within the range of ±10% of the amount directed in the monograph, transfer into the above ignited container, and weigh it accurately. Ignite under the conditions directed in the monograph, and, after cooling, weigh accurately. Use a desiccator (silica gel) for the cooling.

2.44 Residue on Ignition Test

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia. The parts of the text that are not harmonized are marked with symbols (♦ ♦). ♦The Residue on Ignition Test is a method to measure the amount of residual substance not volatilized from a sample when the sample is ignited in the presence of sulfuric acid according to the procedure described below. This test is usually used for determining the content of inorganic impurities in an organic substance.

The description, for example, “not more than 0.1% (1 g)” in a monograph, indicates that the mass of the residue is not more than 1 mg per 1 g of the substance in the test in which about 1 g of the substance is weighed accurately and ignited by the procedure described below, and “after drying” indicates that the sample is tested after being dried under the conditions specified in the test for Loss on drying. ♦

1. Procedure

Ignite a suitable crucible (for example, silica, platinum, quartz or porcelain) at 600 ± 50°C for 30 minutes, cool the crucible in a desiccator (silica gel or other suitable desiccant) and weigh it accurately.

Take the amount of test sample specified in the individual monograph in the crucible and weigh the crucible accurately.

Moisten the sample with a small amount (usually 1 mL) of sulfuric acid, then heat gently at a temperature as low as practicable until the sample is thoroughly charred. After cooling, moisten the residue with a small amount (usually 1 mL) of sulfuric acid, heat gently until white fumes are no longer evolved, and ignite at 600 ± 50°C until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Cool the crucible in a desiccator (silica gel or other suitable desiccant), weigh accurately and calculate the percentage of residue.

Unless otherwise specified, if the amount of the residue so obtained exceeds the limit specified in the individual monograph, repeat the moistening with sulfuric acid, heating and ignition as before, using a 30-minute ignition period, until two consecutive weighings of the residue do not differ by more than 0.5 mg or until the percentage of residue complies with the limit in the individual monograph.

2.45 Refractive Index Determination

Refractive Index Determination is a method to measure the ratio of the velocity of light in air to that in the sample. Generally, when light proceeds from one medium into another, the direction is changed at the boundary surface. This phenomenon is called refraction. When light passes from the first isotropic medium into the second, the ratio of the sine of the angle of incidence, \( i \), to that of the angle of refraction, \( r \), is constant with regard to these two media and has no relation to the angle of incidence. This ratio is called the refractive index of the second medium with respect to the first, or the relative refractive index, \( n \).

\[
 n = \frac{\sin i}{\sin r}
\]

The refractive index obtained when the first medium is a vacuum is called the absolute refractive index, \( N \), of the second medium.

In isotropic substances, the refractive index is a characteristic constant at a definite wavelength, temperature, and pressure. Therefore, this measurement is applied to purity test of substances, or to determination of the composition of homogeneous mixtures of two substances.

The measurement is usually carried out at 20°C, and the D line of the sodium spectrum is used for irradiation. This value is expressed as \( nD \).

1. Procedure

For the measurement of refractive index, usually the Abbé
refractometer is used at a temperature in the range of ±0.2°C of that directed in the monograph. Use of the Abbé refractometer permits direct reading of \( n_0 \) under incandescent light, with a measurable range from 1.3 to 1.7, and an attainable precision of 0.0002.

### 2.46 Residual Solvents Test

Residual Solvents Test is a test to determine the amounts of residual organic solvents in pharmaceuticals by using gas chromatography (<2.02> or other suitable methods. If only solvents with low toxic potential to man are present in pharmaceuticals, the test of loss on drying (<2.41>) can be applied in place of gas chromatography.

1. **Procedure and Test Method**

   Perform the test by using gas chromatography (<2.02>) or other suitable methods.

   The items necessary for conducting the test should previously be specified so that the test method is suitable for determining the objective residual solvents. For gas chromatography, the items usually necessary to specify are the quantity of sample and reference standard (reference substance) for the test, method for preparing sample and standard solutions, injection amounts of sample and standard solutions to gas chromatograph, calculation formula, operating conditions for head-space apparatus and gas chromatography, and system suitability.

### 2.47 Osmolarity Determination

Osmolarity Determination is a method for measuring the osmotic concentration of the sample solution from the extent of the freezing-point depression.

When a solution and a pure solvent are separated by a semipermeable membrane, through which the solvent can pass freely, but the solute cannot, a part of the solvent passes into the solution compartment through the membrane. The pressure difference produced between the two compartments concomitantly with the solvent migration through the membrane, is defined as the osmotic pressure \( \Pi \) (Pa). The osmotic pressure is a physical quantity depending on the total of the molecular species present, including neutral molecules and ions, and does not depend on the kind of solute. A solution property, such as osmotic pressure, freezing-point depression, boiling-point elevation etc., which depends not on the kind of solute, but on the total number of all molecular species, is called a colligative property of a solution.

The osmotic pressure of a polymer solution can be measured directly as the hydrostatic pressure difference between two compartments separated by a semipermeable membrane, such as a cellulose membrane. However, this is not applicable to a solution containing low molecular species, which can pass through a semipermeable membrane. Though the osmotic pressure of such a solution cannot be measured directly, the direction and extent of solvent migration through biological membranes can be predicted from the total number of all molecular species present when the solution is placed under physiological conditions. Other colligative properties of a solution such as freezing-point depression, boiling-point elevation, vapor-pressure depression, etc. can be directly obtained by observing changes of temperature and/or pressure, etc. These solution properties depend on the total number of ionic and neutral species in the solution in the same way as the osmotic pressure, and the molecular particle concentration is defined as the osmotic concentration. The osmotic concentration can be defined in two ways, one being mass-based concentration (osmolality, mol/kg) and the other, volume-based concentration (osmolality, mol/L). In practice, the latter is more convenient.

Unless otherwise specified, the freezing-point depression method is used for measuring the osmotic concentration. The method is based on the linear dependency of the freezing-point depression \( \Delta T \) (°C) upon the osmolality \( m \) (mol/kg), as expressed in the following equation,

\[ \Delta T = K \cdot m \]

In this equation, \( K \) is the molal freezing-point depression constant, and it is known to be 1.86°C kg/mol for water. Since the constant \( K \) is defined on the basis of molarity, the molar osmotic concentration can be obtained from the above equation. In the dilute osmotic concentration range, osmolality \( m \) (mol/kg) can be assumed to be numerically equal to osmolality \( c \) (mol/L). Thus, the conventional osmolality (mol/L) and the unit of osmole (Osm) are adopted in this test method. One Osm means that the Avogadro number \((6.022 \times 10^{23})/\text{mol}\) of species is contained in 1 L of solution. Usually the osmotic concentration is expressed as the sub-multiple milliosmole (mOsm, mosmol/L) in the Pharmacopoeia.

1. **Apparatus**

   Usually, the osmotic concentration of a solution can be obtained by measuring the extent of the freezing-point depression. The apparatus (osmometer) is composed of a sample cell for a fixed volume of sample solution and a cell holder, a cooling unit and bath with a temperature regulator, and a thermistor for detecting temperature.

2. **Procedure**

   A fixed volume of the test solution is introduced into the sample cell, as indicated for the individual apparatus.

   The apparatus must first be calibrated by the two-point calibration method by using osmolar standard solutions. For the calibration, select two different standard solutions just covering the expected osmolar concentration of a sample solution. Other than the indicated osmolar standard solutions in the Table below, water can also be used as a standard solution (0 mOsm) for measuring low osmolar sample solutions (0 – 100 mOsm). Next, after washing the sample cell and the thermistor as indicated for the individual apparatus, measure the degree of the freezing-point depression caused by a sample solution. Using the above-mentioned relation of osmolar concentration \( m \) and \( \Delta T \), the osmolality of a sample solution can be obtained, and it is assumed to be numerically equal to the osmolality.

   In the case of higher osmolar solutions over 1000 mOsm, dilute the sample by adding distilled water and prepare \( n \) times diluted sample solution (1 in \( n \)). Measure the osmolality of the diluted solution, as described above. In this case, it is necessary to state that the calculated osmolality for the sample (see below) is an apparent osmolality obtained by the dilution method. When the dilution method is applied,
the dilution number should be selected so that the expected osmolarity is nearly equal to that of physiological saline solution.

In the case of solid samples, such as freeze-dried medicines, prepare a sample solution by dissolving the solid using the indicated solution for dissolution.

3. Suitability of the apparatus

After the calibration of the apparatus, a suitability test must be done by repeating the measurement of osmolarity for one of the standard solutions not less than 6 times. In performing the test, it is advisable that the osmolarity of a sample solution and the selected standard solution are similar to each other. In this test, the repeatability of measured values and the deviation of the average from the indicated value should be less than 2.0% and 3.0%, respectively. When the requirement is not met, calibrate the apparatus again by the two-point calibration method, and repeat the test.

4. Preparation of the osmolar standard solutions

Weigh exactly an amount indicated in Table 2.47-1 of sodium chloride (standard reagent), previously dried between 500°C and 650°C for 40 to 50 minutes and allowed to cool in a desiccator (silica gel). Dissolve the weighed sodium chloride in exactly 100 g of water to make the corresponding osmolar standard solution.

5. Osmolar ratio

In this test method the osmolar ratio is defined as the ratio of osmolarity of a sample solution to that of the isotonic sodium chloride solution. The ratio can be used as a measure of isotonicity of sample solution. Since the osmolarity of the isotonic sodium chloride solution (NaCl 0.900 g/100 mL) \(c_S\) (mOsm) is assumed to be constant (286 mOsm), the osmolar ratio of a sample solution, of which the osmolarity is \(c_T\) (mOsm), can be calculated by means of the following equation,

\[
\text{Osmolar ratio} = \frac{c_T}{c_S}
\]

\(c_S = 286\) mOsm

When the measurement is done by the dilution method, because the sample has an osmolarity over 1000 mOsm, the apparent osmolarity of the sample solution \(c_T\) can be calculated as \(n \cdot c_T' = c_T\), in which \(n\) is the dilution number and \(c_T'\) is the measured osmolarity for the diluted solution. In this calculation, a linear relation between osmolarity and solute concentration is assumed. Thus when the dilution measurement is performed, the dilution number must be stated as (1 in \(n\)).

2.48 Water Determination (Karl Fischer Method)

Water Determination is a method to determine water content in sample materials, utilizing the fact that water reacts with iodine and sulfur dioxide quantitatively in the presence of a lower alcohol such as methanol, and an organic base such as pyridine. The reaction proceeds in the manner shown in the following equation:

\[
\ce{I2 + SO2 + 3C2H5N + CH3OH + H2O \rightarrow 2(C2H5N^+H)I^- + (C2H5N^+H)OSO2OCH3}
\]

In this measurement there are two methods different in iodine-providing principle: one is the volumetric titration method and the other, the coulometric titration method. In the former, iodine is previously dissolved in a reagent for water determination, and water content is determined by measuring the amount of iodine consumed as a result of reaction with water. In the latter, iodine is produced by electrolysis of Karl Fisher reagent containing iodide ion. Based on the quantitative reaction of the generated iodine with water, the water content in a sample specimen can be determined by measuring the quantity of electricity which is required for the production of iodine during the titration.

\[
2I^- \rightarrow I_2 + 2e^-
\]

1. Volumetric titration

1.1. Apparatus

Generally, the apparatus consists of automatic burettes, a titration flask, a stirrer, and equipment for amperometric titration at constant voltage or potentiometric titration at constant current.

The Karl Fischer TS is extremely hygroscopic, so the apparatus should be designed to be protected from atmospheric moisture. Desiccants such as silica gel or calcium chloride for water determination are used for moisture protection.

1.2. Reagents

(i) Chloroform for water determination—To 1000 mL of chloroform add 30 g of synthetic zeolite for drying, stopper tightly, allow to stand for about 8 hours with occasional gentle shaking, then allow to stand for about 16 hours, and collect the clear layer of chloroform. Preserve the chloroform, protecting it from moisture. The water content of this chloroform should not be more than 0.1 mg per mL.

(ii) Methanol for water determination—To 1000 mL of methanol add 30 g of synthetic zeolite for drying, stopper tightly, allow to stand for about 8 hours with occasional gentle shaking, then allow to stand for about 16 hours, and collect the clear layer of methanol. Preserve the methanol, protecting it from moisture. The water content of this methanol should not be more than 0.1 mg per mL.

(iii) Propylene carbonate for water determination—To 1000 mL of propylene carbonate add 30 g of synthetic zeolite for drying, stopper tightly, allow to stand for about 8 hours with occasional gentle shaking, then allow to stand for about 16 hours, and collect the clear propylene carbonate layer. Preserve this protection from moisture. The water content should not be more than 0.3 mg per mL.

(iv) Diethylene glycol monoethyl ether for water determination—To 1000 mL of diethylene glycol monoethyl ether add 30 g of synthetic zeolite for drying, stopper tightly,
allow to stand for about 8 hours with occasional gentle shaking, then allow to stand for about 16 hours, and collect the clear layer of diethylene glycol monoethyl ether. Preserve the diethylene glycol monoethyl ether, protecting it from moisture. The water content of this diethylene glycol monoethyl ether should not be more than 0.3 mg per mL.

(v) Pyridine for water determination—Add potassium hydroxide or barium oxide to pyridine, stopper tightly, and allow to stand for several days. Distill and preserve the purified and dried pyridine, protecting it from moisture. The water content of this pyridine should not be more than 1 mg per mL.

(vi) Imidazole for water determination—Use imidazole for thin-layer chromatography, of which the water content should not be more than 1 mg per g.

(vii) 2-Methylaminopyridine for water determination—Distill and preserve 2-methylaminopyridine, protecting it from moisture. The water content of this 2-methylaminopyridine should not be more than 1 mg per mL.

1.3. Preparation of test solutions and standard solutions

1.3.1. Karl Fischer TS for water determination

The Karl Fischer TS is preserved in a cold place, protecting it from light and moisture.

1.3.1.1. Preparation

Prepare according to the following method (i), (ii) or (iii). Additives may be added for the purpose of improving the stability or other performances if it is confirmed that they give almost the same results as those obtained from the specified method.

(i) Preparation 1
Dissolve 63 g of iodine in 100 mL of pyridine for Karl Fischer method, cool the solution in ice bath, and pass dried sulfur dioxide gas through this solution until the mass increase of the solution reaches 32 g. Then make up to 500 mL by adding chloroform for Karl Fischer method or methanol for Karl Fischer method, and allow to stand for more than 24 hours before use.

(ii) Preparation 2
Dissolve 102 g of imidazole for Karl Fischer method in 350 mL of diethylene glycol monoethyl ether for water determination, cool the solution in ice bath, and pass dried sulfur dioxide gas through this solution until the mass increase of the solution reaches 64 g, keeping the temperature between 25°C and 30°C. Then dissolve 50 g of iodine in this solution, and allow to stand for more than 24 hours before use.

(iii) Preparation 3
Pass dried sulfur dioxide gas through 220 mL of propylene carbonate for water determination until the mass increase of the solvent reaches 32 g. To this solution, add 180 mL of propylene carbonate, or diethylene glycol monoethyl ether for water determination, in which 81 g of 2-methylaminopyridine for Karl Fischer method is dissolved and cooled in ice bath. Then dissolve 36 g of iodine in this solution, and allow to stand for more than 24 hours before use.

1.3.1.2. Standardization

According to the procedure described below, take a suitable quantity of methanol for water determination in a dried titration flask, and titrate the water contaminated with Karl Fischer TS to make the content of the flask anhydrous. Then, add exactly 10 mL of Karl Fischer TS to this solution in the flask, and titrate it with the prepared standard water-methanol solution to the end point. Calculate the water concentration in the standard water-methanol solution, $f$(mg/mL), by using the following equation:

$$f$(mg/mL) = \frac{f$(mg/mL) $\times 10 (mL)}{Volume of the standard water-methanol solution consumed for titration (mL)}

1.3.2. Standard water-methanol solution

Standard water-methanol solution is preserved in a cold place, protecting it from light and moisture.

1.3.2.1. Preparation

Take 500 mL of methanol for water determination in a dried 1000-mL volumetric flask, add 2.0 mL of water, and adjust with the methanol to make 1000 mL.

Perform the standardization of this solution, followed by the procedure for Karl Fischer TS. Preserve it in a cool place, protecting it from light and moisture.

1.3.2.2. Standardization

According to the procedure described below, take a suitable quantity of methanol for water determination in a dried titration flask, and titrate the water contaminated with Karl Fischer TS to make the content of the flask anhydrous. Then, add exactly 10 mL of Karl Fischer TS to this solution in the flask, and titrate it with the prepared standard water-methanol solution to the end point. Calculate the water concentration in the standard water-methanol solution, $f$(mg/mL), by using the following equation:

$$f$(mg/mL) = \frac{Amount of water taken (H2O) (mg)}{Volume of Karl Fischer TS consumed for titration of water (H2O) (mL)}

1.4. Procedure

As a rule, the titration of water with a Karl Fischer TS should be performed at the same temperature as that at which the standardization was done, with protection from moisture. The apparatus is equipped with a variable resistor in the circuit, and this resistor is manipulated so as to maintain a constant voltage (mV) between two platinum electrodes immersed in the solution to be titrated. The variable current (mA) can be measured (Amperometric titration at constant voltage). During titration with Karl Fischer TS, the current in the circuit varies noticeably, but returns to the original value within several seconds. At the end of a titration, the current stops changing and persists for a certain time (usually, longer than 30 seconds). When this electric state has been attained, it is designated as the end point of titration.

Otherwise, the manipulation of the resistor serves to pass a definite current between two platinum electrodes. The variable potential (mV) can be measured (Potentiometric titration at constant current). With the progress of titration of water with a Karl Fischer TS, the value indicated by the potentiometer in the circuit decreases suddenly from a polarization state of several hundreds (mV) to the non-polarization state, but it returns to the original value within several seconds. At the end of titration, the non-polarization state persists for a certain time (usually, longer than 30 seconds). When this electric state has been attained, it is designated as the end point of titration.

In the case of back titration, when the amperometric titration method is used at constant voltage, the needle of microammeter is out of scale during excessive presence of Karl Fischer TS, and it returns rapidly to the original position when the titration system has reached the end point.
the case of the potentiometric titration method at constant
current in the back titration mode, the needle of the mil-
vilometer is at the original position during excessive
presence of Karl Fischer TS. Finally a definite voltage is indi-
cated when the titration system has reached the end point.

Unless otherwise specified, the titration of water with Karl
Fischer TS can be performed by either one of the following
methods. Usually, the end point of the titration can be ob-
served more clearly in the back titration method, compared
with the direct titration method.

1.4.1. Direct titration

Unless otherwise specified, proceed by the following
method. Take a suitable quantity of methanol for water
determination in a dried titration flask, and titrate the water
contaminated with Karl Fischer TS to make the content of
the flask anhydrous. Take a quantity of sample specimen
containing 5 to 30 mg of water, transfer it quickly into the
titration flask, dissolve by stirring, and titrate the solution to
be examined with Karl Fischer TS to the end point under
vigorous stirring.

In the case of an insoluble sample specimen, powder the
sample quickly, weigh a suitable amount of the sample con-
taining 5 to 30 mg of water, and transfer it quickly into the
titration vessel, stir the mixture for 5 – 30 minutes, protect-
ing it from moisture, and perform a titration under vigorous
stirring. Alternatively, in the case of a sample specimen
which is insoluble in the solvent for water determination or
which interfere with the Karl Fisher reaction, water in the
sample can be removed by heating under a stream of nitro-
gen gas, and introduced into the titration vessel by using a
blank test must be done under the same conditions as used
for the sample test, and the data must be corrected, accord-
ingly.

\[
\text{Volume of Karl Fischer TS consumed for titration (mL)} \times f'(mg/mL)
\]

Water (H$_2$O) % = \frac{\text{Volume of Karl Fischer TS added (mL)}}{\text{Amount of sample (mg)}} \times 100

1.4.2. Back titration

Unless otherwise specified, proceed by the following
method. Take a suitable quantity of methanol for water de-
termination in the dried titration vessel, and titrate the water
contaminated with Karl Fischer TS to make the content of
the flask anhydrous. Take a suitable quantity of sample
specimen having 5 – 30 mg of water, transfer the sample
quickly into the titration vessel, dissolve it in the solution by
stirring, add an excessive and definite volume of Karl Fisher
TS, and then titrate the solution with the standard water-
methanol solution to the end point under vigorous stirring.

In the case of an insoluble sample specimen, powder the
sample quickly, weigh a suitable amount accurately, transfer
it quickly into the titration vessel, and add an excessive and
definite volume of Karl Fischer TS. After stirring for 5 – 30
minutes, with protection from moisture, perform the titra-
tion under vigorous stirring.

Water (H$_2$O) % = \frac{\left[ \text{Volume of Karl Fischer TS added (mL)} \times f'(mg/mL) \right] - \left[ \text{Volume of the standard water-methanol solution consumed for titration (mL)} \times f'(mg/mL) \right]}{\text{Amount of sample (mg)}} \times 100

2. Coulometric titration

2.1. Apparatus

Usually, the apparatus is comprised of a titration flask
equipped with an electrolytic cell for iodine production, a
stirrer, and a potentiometric titration system at constant cur-
rent. The iodine production system is composed of an anode
and a cathode, separated by a diaphragm. The anode is im-
mersed in the anolyte solution for water determination and
the cathode is immersed in the catholyte solution for water
determination. Both electrodes are usually made of plati-
num-mesh.

Because both the anolyte and the catholyte solutions for
water determination are strongly hygroscopic, the titration
system should be protected from atmospheric moisture. For
this purpose, silica gel or calcium chloride for water determi-
nation can be used.

2.2. Preparation of anolyte and catholyte solutions for
water determination

Electrolytic solutions shall consist of an anolyte solution
and a catholyte solution, the preparations of which are de-
scribed below.

2.2.1. Preparation 1

(i) Anolyte for water determination—Dissolve 102 g of
imidazole for water determination in 900 mL of methanol
for water determination, cool the solution in ice bath, and
pass dried sulfur dioxide gas through the solution, which is
kept below 30°C. When the mass increase of the solution has
reached 64 g, the gas flow is stopped and 12 g of iodine is
dissolved by stirring. Then drop a suitable amount of water
into the solution until the color of liquid is changed from
brown to yellow, and add methanol for water determination
to make up 1000 mL.

(ii) Catholyte for water determination—Dissolve 24 g of
diethanolamine hydrochloride in 100 mL of methanol for
water determination.

2.2.2. Preparation 2

(i) Anolyte for water determination—Dissolve 40 g of
1,3-di(4-pyridyl)propane and 30 g of diethanolamine in
about 200 mL of methanol for water determination, and
pass dried sulfur dioxide gas through the solution. When the
mass increase of the solution has reached 25 g, the gas flow
is stopped. Add 50 mL of propylene carbonate, and dissolve
6 g of iodine in the solution. Then make up the solution to
500 mL by addition of methanol for water determination and
drop in a suitable amount of water until the color of liq-
uid is changed from brown to yellow.

(ii) Catholyte for water determination—Dissolve 30 g of
choline hydrochloride into methanol for water determination
and adjust the volume to 100 mL by adding the methanol.

2.2.3. Preparation 3

(i) Anolyte for water determination—Dissolve 100 g of
diethanolamine in 900 mL of methanol for water determi-
nation or a mixture of methanol and chloroform for water de-
termination (3:1), and pass dried sulfur dioxide gas through the solution. When the mass increase of the solution has reached 64 g, the gas flow is stopped. Dissolve 20 g of iodine in the solution, and drop in a suitable amount of water until the color of liquid is changed from brown to yellow.

(ii) Catholyte for water determination—Dissolve 25 g of lithium chloride in 1000 mL of a mixture of methanol for water determination and nitroethane (4:1).

2.3. Procedure
Take a suitable volume of an anolyte for water determination in the titration vessel, immerse in this solution a pair of platinum electrodes for potentiometric titration at constant current. Then immerse the iodine production system filled with a catholyte for water determination in the anolyte solution. Switch on the electrolytic system and make the content of the titration vessel anhydrous. Next take an accurately weighed amount of a sample specimen containing 0.2 – 5 mg of water, add it quickly to the vessel, dissolve by stirring, and perform the titration to the end point under vigorous stirring.

When a sample specimen cannot be dissolved in the anolyte, powder it quickly, and add an accurately weighed amount of the sample estimated to contain 0.2 – 5 mg of water to the vessel. After stirring the mixture for 5 – 30 minutes, with protection from atmospheric moisture, perform the titration under vigorous stirring. Alternatively, in the case of an insoluble solid or a sample containing a component which interferes with the Karl Fisher reaction, water in the sample can be removed by heating, and carried by a nitrogen gas flow into the titration vessel, by using a water evaporation technique.

Determine the quantity of electricity (C) [i.e. electric current (A) × time (s)] required for the production of iodine during the titration, and calculate the water content (%) in the sample specimen by use of the following equation.

Though the titration procedure should be performed under atmospheric conditions at low humidity, if the effect of atmospheric moisture cannot be avoided, for instance, if a long time is required for extraction and titration of water, a blank test must be done under the same conditions as used for the sample test, and the data must be corrected, accordingly.

\[
\text{Water (H}_2\text{O)} \% = \frac{\text{Quantity of electricity required for iodine production (C)}}{10.72 \text{ (C/mg)} \times \text{Amount of sample (mg)}} \times 100
\]

10.72: quantity of electricity corresponding to 1 mg of water (C/mg)

2.49 Optical Rotation Determination

Optical Rotation Determination is a method for the measurement of the angular rotation of the sample using a polarimeter.

Generally, the vibrations of light take place on planes perpendicular to the direction of the beam. In case of the ordinary light, the directions of the planes are unrestricted, while in case of the plane polarized light, commonly called as polarized light, the vibrations take place on only one plane that includes the advancing direction of the beam. And it is called that these beams have plane of polarization. Some drugs in the liquid state or in solution have a property of rotating the plane of the polarized light either to the right or to the left. This property is referred to as optical activity or optical rotation, and is inherently related to the chemical constitution of the substance.

The optical rotation is a degree of rotation of polarized plane, caused by the optically active substance or its solution, and it is measured by the polarimeter. This value is proportional to the length of the polarimeter tube, and is also related to the solution concentration, the temperature and the measurement wavelength. The character of the rotation is indicated by the direction of the rotation, when facing to the advancing direction of the polarized light. Thus in case of rotation to the right, it is called dextrorotatory and expressed by placing plus sign (+), while in case of rotation to the left, it is called levorotatory and expressed by placing minus sign (−) before the figure of the angular rotation. For example, +20° means 20° of rotation to the right, while −20° means 20° of rotation to the left.

The angular rotation α; means degree of rotation, when it is measured at t°C by using specific monochromatic light \(x\) (expressed by wavelength of light source or the specific beam name). Usually, the measurement is performed at 20°C or 25°C, with a polarimeter tube of 100 mm in length, and with the D line of sodium lamp.

The specific rotation is expressed by the following equation:

\[
[\alpha]_D = \frac{\alpha}{l} \times 100
\]

\(t\): The temperature of measurement.
\(\lambda\): The wavelength or the name of the specific monochromatic light (in the case of the Sodium D line, it is described as D).
\(\alpha\): The angle, in degrees, of rotation of the plane of the polarized light.
\(l\): The thickness of the layer of sample solution, i.e., the length of the polarimeter tube (mm).
\(c\): Drug concentration in g/mL. When an intact liquid drug is used for the direct measurement without dilution by an appropriate solvent, \(c\) equals to its density (g/mL). However, unless otherwise specified, the specific gravity is conventionally used in stead of the density.

The description in the monograph, for example, “\([\alpha]_D = -33.0°\) − 36.0° (after drying, 1 g, water, 20 mL, 100 mm)," means the measured specific rotation \([\alpha]_D\) should be in the range of −33.0° and −36.0°, when 1 g of accurately weighed sample dried under the conditions, specified in the test item of Loss on drying, is taken, and dissolved in water to make exactly 20 mL, then put in the polarimeter tube of 100 mm length, of which temperature is kept at 20°C.
2.50 Endpoint Detection Methods in Titrimetry

Titrimetry is a method or a procedure for volumetric analysis, which is usually classified into acid-base titration (neutralization titration or pH titration), precipitation titration, complexation titration, oxidation-reduction titration, etc., according to the kind of reaction or the nature of the phenomenon occurring between the titrate and the titrant (standard solution for volumetric analysis). Furthermore, titration performed in a noneaqueous solvent is generally called noneaqueous titration, which is frequently used for volumetric analysis of weak acids, weak bases, and their salts. The endpoint in titrimetry can be detected by color changes of indicators and/or by changes of electrical signals such as electrical potential or electrical current.

The indicator method is one of the endpoint detection methods in titrimetry. In this method the color of an indicator dye, dissolved in the titrate, changes dramatically in the vicinity of the equivalence point due to its physico-chemical character, and this property is used for visual endpoint detection. Selection of an indicator and specification of the color change induced in the respective titration system, should be described in the individual monograph. An appropriate indicator should change color clearly, in response to a slight change in physico-chemical properties of the titrate, such as pH, etc., in the vicinity of the equivalence point.

Regarding the electrical endpoint detection methods, there are an electrical potential method and an electrical current method, which are called potentiometric and amperometric titration methods, respectively. They are generically named electrometric titration. In the potentiometric titration method, the endpoint of a titration is usually determined to be the point at which the differential potential change becomes maximum or minimum as a function of the quantity of titrant added. In the amperometric titration method, unless otherwise specified, a bi-amperometric titration method is used, and the endpoint is determined by following the change of microcurrent during the course of a titration. Furthermore, the quantity of electricity (electrical current \( \times \) time) is often used as another electrochemical signal to follow a chemical reaction, as described in Coulometric Titration under Water Determination <2.49>.

The composition of a titration system, such as amount of specimen, solvent, standard solution for volumetric analysis, endpoint detection method, equivalent amount of substance to be examined (mg)/standard solution (mL), should be specified in the individual monograph. Standardization of the standard solution and titration of a specimen are recommended to be done at the same temperature. When there is a marked difference in the temperatures at which the former and the latter are performed, it is necessary to make an appropriate correction for the volume change of the standard solution due to the temperature difference.

1. Indicator Method

Weigh an amount of a specimen in a flask or a suitable vessel as directed in the monograph or in “Standard Solutions for Volumetric Analysis”, and add a specified quantity of solvent to dissolve the specimen. After adding a defined indicator to the solution to prepare the titrate, titrate by adding a standard solution for volumetric analysis by using a buret. In the vicinity of the endpoint, observe the color change induced by the cautious addition of 0.1 mL or less of the titrant. Calculate the quantity of titrant added from the readings on the scale of the buret used for the titration at the starting point and at the endpoint at which the specified color change appears, as directed in the individual monograph or in the “Standard Solutions for Volumetric Analysis”. Although addition of the volumetric standard solution by buret is usually done manually, an automatic buret can also be used.

Unless otherwise specified, perform a blank determination according to the following method, and make any necessary correction.

Measure a specified quantity of solvent, as directed in the monograph or in the “Standard Solutions for Volumetric Analysis”, and titrate as directed. The required quantity of the standard solution added to reach a specified color change, is assumed to be the blank quantity for the titration system. However, when the blank quantity is too small to evaluate accurately, the quantity can be assumed to be zero.

2. Electrical Endpoint Detection Methods

2.1. Potentiometric titration

2.1.1. Apparatus

The apparatus consists of a beaker to contain the specimen, a buret for adding a standard solution, an indicator electrode and a reference electrode, a potentiometer for measuring potential difference between the electrodes or an adequate pH meter, a recorder, and a stirrer for gentle stirring of the solution to be examined. Separately, an automatic titration apparatus assembled from suitable units and/or parts, including a data processing system, can also be used.

In this titration method, unless otherwise specified, indicator electrodes designated in Table 2.50-1 are used according to the kind of titration. As a reference electrode, usually a silver-silver chloride electrode is used. Besides the single indicator electrodes as seen in Table 2.50-1, a combined reference electrode and indicator electrode can also be used.

When the potentiometric titration is carried out by the pH measurement method, the pH meter should be adjusted according to the pH Determination <2.54>.

2.1.2. Procedure

Weigh a defined amount of a specimen in a beaker, and add an indicated quantity of solvent to dissolve the specimen, as directed in the monograph. After the potential difference \( E \) (mV) or the pH value of the solvent to be used for titration has reached a stable value, immerse both reference and indicator electrodes, which have previously been washed with the solvent being used, in the solution to be examined, and titrate with a standard solution for volumetric analysis with gentle stirring of the solution. During the titration, the tip of the buret should be dipped into the solution, to be examined. The endpoint of titration is determined by following the variation of the potential difference between two electrodes as a function of the quantity of titrant added. In the vicinity of the endpoint, the amounts of a titrant added should be 0.1 mL or less for adequate titrimetry. Plot the obtained potential values along the ordinate and the quantity of a titrant added \( V \) (mL) along the abscissa to draw a titration curve, and obtain the endpoint from the
maximum or the minimum value of $\Delta E/\Delta V$ or from the value of electromotive force or pH corresponding to the equivalence point.

Unless otherwise specified, the decision of the endpoint in this method is usually made by either of the following methods.

(i) Drawing method

Usually, draw two parallel tangent lines with a slope of about 45° to the obtained titration curve. Next, draw a 3rd parallel line at the same distance from the previously drawn two parallel lines, and decide the intersection point of this line with the titration curve. Further, from the intersection point, draw a vertical line to the abscissa, and read the quantity of titrant added as the endpoint of the titration.

Separately, the endpoint of the titration can also be obtained from the maximum or the minimum of the differential titration curve ($\Delta E/\Delta V$ vs. $V$).

(ii) Automatic detection method

In the case of potentiometric titration using an automatic titration system, the endpoint can be determined by following the respective instrumental indications. The endpoint is decided either by following the variation of the differential potential change or the absolute potential difference as a function of the quantity of titrant added: in the former case the quantity given by the maximum or the minimum of the differential values, and in the latter the quantity given by the indicator reaching the endpoint previously set for the individual titration system, are assumed to be the endpoint volumes, respectively.

2.2.2. Procedure

Weigh a defined amount of a specimen in a beaker, and add an indicated quantity of solvent to dissolve the specimen, as directed in the individual monograph. Next, after washing the two indicator electrodes with water, immerse both electrodes in the solution to be examined, apply a constant voltage suitable for measurement across two electrodes by using an appropriate device, and titrate the solution with a standard solution for volumetric analysis. During the titration, the tip of the buret should be dipped into the solution to be examined. The endpoint of titration is determined by following the changes of microcurrent between the two electrodes as a function of the quantity of titrant added. In the vicinity of the endpoint, the amounts of the titrant added should be 0.1 mL or less for adequate titrimetry. Plot the obtained current values along the ordinate and the quantity of the titrant added $V$ (mL) along the abscissa to draw a titration curve, and usually take the inflection point of the titration curve (the point of intersection given by the extrapolation of two straight lines before and after the inflection) as the endpoint in amperometric titration.

The blank test in this titration is usually performed as follows: Take a volume of the solvent specified in the individual monograph or in the “Standard Solution for Volumetric Analysis”, and use this as the sample solution. Determine the amount of the volumetric standard solution needed for giving the endpoint, and use this volume as the blank. If this volume is too small to determine accurately, the blank may be considered as 0 (mL).

Unless otherwise specified, the endpoint in this titration is decided by either of the following methods.

(i) Drawing method

Usually, extrapolate the two straight lines before and after the inflection, and obtain the inflection point of the titration curve. Next, read the quantity of titrant added at the inflection point, and assume this point to be the endpoint.

(ii) Automatic detection method

In the case of amperometric titration using an automatic titration system, the endpoint can be determined by following the instrumental indications. The endpoint is decided by following the variation of the indicator current during the course of a titration, and the quantity of titrant added is assumed to be that at which the current has reached the endpoint current set previously for the individual titration system.

When atmospheric carbon dioxide or oxygen is expected to influence the titration, a beaker with a lid should be used, and the procedure should be carried out in a stream of an inert gas, such as nitrogen gas. Further, when a specimen is expected to be influenced by light, use a light-resistant container to avoid exposure of the specimen to direct sunlight.

### 2.51 Conductivity Measurement

Conductivity Measurement is a method for the measuring the flowability of electric current in an aqueous solution.
The measurement is made with a conductivity meter or a resistivity meter, and is used, for example, in the purity tests in monographs. The method is applied to evaluate the test item “Conductivity (Electrical Conductivity)” specified in the monographs. Further it is also used for monitoring the quality of water in the preparation of highly purified water. However, when applying this method for monitoring the quality of water, the details of measurement should be specified by the user, based on the principles described here.

Conductivity of a solution \[ \kappa \, (\text{S} \cdot \text{m}^{-1}) \] is defined as the reciprocal of resistivity \[ \rho \, (\Omega \cdot \text{m}) \], which is an indicator of the strength of ionic conductivity for a fluid conductor. Resistivity is defined as the product of electrical resistance per unit length and cross-sectional area of a conductor. When resistivity is defined as the product of electrical resistance per unit length and cross-sectional area of a conductor. When resistivity is \[ \rho \], cross-section area \[ A \, (\text{m}^2) \], and length \[ l \, (\text{m}) \], resistance \[ R \, (\Omega) \] can be expressed by the following equation.

\[
R = \rho \left( \frac{l}{A} \right)
\]

Thus, conductivity \[ \kappa \] is expressed as follows,

\[
\kappa = \frac{1}{\rho} = \left( \frac{1}{R} \right) \left( \frac{l}{A} \right)
\]

If \( l/A \) is known, the conductivity \( \kappa \) can be obtained by measuring resistance \( R \) or conductance \( G = \frac{1}{R} \).

In the International System (SI), the unit of conductivity is the Siemens per meter (S·m⁻¹). In practice, conductivity of a solution is generally expressed by \( \mu \text{S} \cdot \text{cm}^{-1} \), and resistivity by \( \Omega \cdot \text{cm} \).

Unless otherwise specified, the reference temperature for the expression of conductivity or resistivity is 20°C.

Items such as the sample preparation method, the necessity of blank correction, the calculation method, the specification value, and the measuring temperature should be described in the monograph, if necessary.

1. Apparatus

A conductivity meter or a resistivity meter is composed of an indicator part (operating panel, display, recording unit) and a detector part, the latter of which includes a conductivity cell. In the conductivity cell a pair of platinum electrodes is embedded. The cell is immersed in a solution, and the resistance or the resistivity of the liquid column between the electrodes is measured. Alternating current is supplied to this apparatus to avoid the effects of electrode polarization. Further, a temperature compensation system is generally contained in the apparatus.

Conductivity measurement is generally performed by using an immersion-type cell. A pair of platinum electrodes, the surfaces of which are coated with platinum black, is fixed in parallel. Both electrodes are generally protected by a glass tube to prevent physical shocks.

When the surface area of the electrode is \( A \, (\text{cm}^2) \), and the separation distance of the two electrodes is \( l \, (\text{cm}) \), the cell constant \( C \, (\text{cm}^{-1}) \) is given by the following equation.

\[
C = \alpha \left( \frac{l}{A} \right)
\]

\( \alpha \) is a dimensionless numerical coefficient, and it is characteristic of the cell design.

In addition to the immersion-type cell, there are flow-through-type and insert-in-pipe-type cells. These cells are set or inserted in an appropriate position in the flow system for monitoring the quality of water continuously or intermittently, during the preparation of highly purified water.

2. Standard Solution of Potassium Chloride

After pulverizing an appropriate amount of potassium chloride for conductivity measurement, dry it at 500 – 600°C for 4 hours. For the preparation of the standard solutions, take the amount of the dried potassium chloride indicated in Table 2.51-1, dissolve it in distilled water previously boiled and cooled, or water with a conductivity less than 2 \( \mu \text{S} \cdot \text{cm}^{-1} \), and adjust to make 1000.0 g. The conductivity and the resistivity of the respective standard solutions at 20°C are shown in Table 2.51-1. These standard solutions should be kept in tightly closed polyethylene or hard glass bottles.

When measurement at 20°C can not be performed, the value of conductivity for the respective standard solution (shown in Table 2.51-1), can be corrected by using the following equation. However, this equation is valid only within the range of 15 – 30°C.

\[ \kappa_T = \kappa_{20} \left[ 1 + 0.021(T - 20) \right] \]

\( T \): Measuring temperature specified in the monograph

\( \kappa_{20} \): Calculated conductivity of the KCl standard solution at \( T^\circ \text{C} \)

\( \kappa_{20} \): Conductivity of the KCl standard solution at 20°C

3. Operating Procedure

3.1. Cell Constant

An appropriate conductivity cell should be chosen according to the expected conductivity of the sample solution. The higher the expected conductivity, the larger the cell constant required for the conductivity cell, so that the electrical resistance is within the measuring range of the apparatus being used. Conductivity cells with a cell constant of the order of 0.1 cm⁻¹, 1 cm⁻¹, or 10 cm⁻¹, are generally used.

For determination or confirmation of the cell constant, an appropriate KCl standard solution should be chosen and prepared, taking account of the expected conductivity of the sample solution to be measured. Rinse the cell several times with distilled water. Next, after rinsing the cell 2 – 3 times with the standard solution used for the cell constant determination, immerse the cell in the standard solution contained in a measuring vessel. After confirming that the temperature of the standard solution is maintained at 20 ± 0.1°C or at the temperature specified in the monograph, measure the resistance \( R_{\text{KCl}} \) or the conductance \( G_{\text{KCl}} \) of the standard solution, and calculate the cell constant \( C \, (\text{cm}^{-1}) \) by use of the following equation.

\[
C = R_{\text{KCl}} \cdot \kappa_{\text{KCl}} \quad \text{or} \quad C = \kappa_{\text{KCl}} / G_{\text{KCl}}
\]

\( R_{\text{KCl}} \): Measured resistance (MΩ)
\( G_{\text{KCl}} \): Measured conductance (\( \mu \text{S} \))

\( \kappa_{\text{KCl}} \): Conductivity of the standard solution being used (\( \mu \text{S} \cdot \text{cm}^{-1} \))
The measured cell constant should be consistent with the given value within 5%. If it is not consistent, coat the electrodes with platinum black again, or replace the cell with a new one.

3.2. Suitability Test for the Apparatus

Using an appropriate KCl standard solution according to the expected conductivity of the sample solution, perform the suitability test for the apparatus. Rinse the conductivity cell several times with distilled water, and rinse again 2 – 3 times with the selected standard solution. Fill the standard solution in the measuring vessel. After confirming that the temperature of the measuring system is maintained at 20 ± 0.1°C, measure the conductivity of the standard solution. When this measuring procedure is repeated several times, the average conductivity should be consistent with an indicated value in Table 1 within 5%. Further, the relative standard deviation should be less than 2%.

3.3. Measurement

After confirmation of the suitability of the apparatus, perform the conductivity measurement for the sample solution. Unless otherwise specified, the preparation method for sample solution should be as specified in the respective monograph. Rinse the conductivity cell several times with distilled water, and rinse again 2 – 3 times with sample solution. Immerse the cell in the sample solution placed in a measuring vessel. If necessary, agitate gently the sample solution. After confirming that the temperature of the sample solution is maintained at 20 ± 0.1°C or at the temperature specified in the monograph, measure the resistance $R_T$ (MΩ) or conductance $G_T$ ($\mu$S) of the sample solution, and calculate the conductivity $\kappa_T$ by using the following equation.

$$\kappa_T = CG_T \quad \text{or} \quad \kappa_T = C/R_T$$

2.52 Thermal Analysis

"Thermal Analysis" is a generic term for a variety of techniques to measure the physical properties of a substance as a function of temperature and/or time. Among the physical properties, phase transitions such as solid/liquid phase transition (melting, freezing) and crystal polymorphism or thermal behavior such as heat evolution or absorption accompanying thermal degradation or chemical reaction can be detected by the techniques of differential thermal analysis (DTA) or differential scanning calorimetry (DSC). DTA is a method for detecting the thermal behavior of a specimen in terms of the temperature change, while DSC employs the heat quantity (enthalpy) change. There is also a method, thermogravimetry (TG), in which the mass change of a specimen caused by dehydration, adsorption, elimination or oxidation etc., is detected as a function of temperature and/or time.

Among the above three different methods, TG can be used as an alternative method for "Loss on Drying <2.45%" or "Water Determination <2.49%". However, it must be confirmed beforehand that no volatile component except for water is included in the test specimen when TG is used as an alternative method for "Water Determination".

1. Method 1 Differential Thermal Analysis (DTA) or Differential Scanning Calorimetry (DSC)

1.1. Apparatus

Apparatus for DTA or DSC is usually composed of a heating furnace, a temperature-controller, a detector, a device for controlling the atmosphere, and an indicator/ recorder.

In a DTA apparatus, a sample specimen and an inert reference material placed in the heating furnace are heated or cooled at a constant rate, and the temperature difference between the sample and the reference, which is detected by a device such as a thermocouple and recorded as a function of time and/or temperature. As an inert reference material, α-Alumina for thermal analysis is usually adopted.

Two kinds of DSC apparatus, based upon different principles are available as shown below.

(i) Input compensation-type differential scanning calorimetry (Input compensation DSC): A sample specimen and the reference material in twin furnaces are programmed to be heated or cooled at a constant rate, and the temperature difference between the sample and the reference, which is detected by a platinum resistance thermometer, is kept at null by controlling the heating unit with a compensation feed-back circuit. The instrument is designed to measure and record continuously the balance of thermal energy applied to each furnace as a function of temperature and/or time.

(ii) Heat flux-type differential scanning calorimetry (Heat flux DSC): A sample specimen and the reference material in twin furnaces are programmed to be heated or cooled at a constant rate, and the temperature difference between the sample and the reference is detected as a difference of heat flux and recorded as a function of temperature and/or time. In heat flux DSC, thermal conductors are adopted so that the heat flux between the sample and the heat reservoir is proportional to the temperature difference between them.

In usual DSC analysis, α-Alumina is used as a reference material, both in Input compensation DSC and in Heat flux DSC. But in some cases, an empty sample container can also be used without any reference material.

1.2. Procedure

A sample specimen and the reference material are put in sample pans, and the furnace is heated or cooled under a controlled temperature program. As the temperature changes, the temperature difference (DTA) or heat quantity change (DSC) that develops between the specimen and the reference is detected and recorded continuously. Apparatus equipped with a data-processor is operated according to the instruction manual provided with the instrument.

A preliminary experiment is needed to determine the appropriate temperature range of measurement, within which a predicted physical change such as melting or polymorphic phase transition will occur, and to confirm that unpredicted thermal changes are not induced in a specimen in that temperature range. In this preliminary test, a wide temperature range (room temperature—the temperature at which degradation begins) can be scanned at a rapid heating rate (10 – 20°C/min). Thereafter, tests by DSC or DTA should be performed at a low heating rate, usually 2°C/min, in the chosen temperature range. However, when a clear heat change cannot be observed, such as in a case of glass-transition, the heating rate may be changed to a higher or a lower rate, as
appropriate for the kind of physical change being observed. By analyzing the measured DTA-curve or DSC-curve, a quantity of heat change and/or a specific temperature (ignition, peak or end temperature) that accompanies a physical change, such as melting or polymorphic phase transition, can be obtained.

1.3. Calibration of the apparatus

1.3.1. Temperature calibration for DTA and DSC

Temperature calibration for DTA and/or DSC apparatus can be performed by using reference substances having an intrinsic thermal property, such as melting point of pure metals or organic substances, or phase transition point of crystalline inorganic salts or oxides. Melting points of Indium for thermal analysis and/or Tin for thermal analysis are usually employed for calibration.

1.3.2. Heat-quantity calibration for DSC

For accurate estimation of a quantity of heat change (enthalpic change) of a sample specimen, caused by a certain physical change accompanying a temperature change, it is necessary to calibrate the apparatus by using appropriate reference substances. As indicated in the section of Temperature calibration, heat-quantity calibration for DSC apparatus can be performed by using appropriate reference substances having a known definite enthalpic change caused by such physical changes as melting of pure metals and/or organic substances, or phase transition of crystalline inorganic salts. Melting points of Indium for thermal analysis and/or Tin for thermal analysis are usually employed for calibration.

1.4. Notes on operating conditions

When DTA or DSC measurements are made, the following items must be recorded: sample size, discrimination of open- or closed-type sample container, heating or cooling rate, measuring temperature range, and kind and flow rate of atmospheric gas.

2. Method 2 Thermogravimetry (TG)

2.1. Apparatus

The construction of a TG apparatus is fundamentally similar to that of DTA or DSC apparatus. However, the detector for TG is a balance, called a thermobalance, which can be classified to hanging- or Roberval's-, and horizontal-type balances. The TG apparatus is designed to detect small mass changes of a specimen, placed at a fixed position on a thermobalance, caused by temperature change of the furnace under a controlled temperature program. Mass change with time and/or temperature is recorded continuously.

2.2. Procedure

A specimen is put in a sample container, which is placed at a fixed position of the thermobalance, then the heating furnace is run under a controlled temperature program. During this temperature change of the furnace, the mass change of a specimen with time and/or temperature is recorded continuously. Apparatus equipped with a data-processor is operated according to the instruction manual provided with the instrument.

When TG is used as an alternative method for “Loss on Drying” or “Water Determination”, the measurement starts at room temperature and ends at a temperature above which no further mass change due to drying and/or vaporization of water can be observed. The standard heating rate is usually 5°C/min, and a linear heating program is recommended. However heating conditions (rate and time span) can be changed as necessary, depending on the kind of specimen and the extent of the measuring temperature range. Further, in TG measurement, dry air or dry nitrogen is usually passed through the heating furnace to ensure rapid elimination of evolved water or other volatile components and to avoid the occurrence of any chemical reaction, such as oxidation. By analyzing the TG curve plotted against time and/or temperature, absolute mass change and/or relative mass change with respect to the initial quantity(%) is obtained.

When the mass change caused by oxidation or degradation of a specimen is measured, a specific temperature range has to be determined beforehand so that stable baselines can be obtained before and after a targetted chemical reaction. Subsequent operating procedures are the same as described above.

2.3. Calibration of the apparatus

2.3.1. Temperature calibration

The Curie temperature of a ferromagnetic substance such as pure Nickel can be used for temperature calibration for TG, based on the occurrence of an apparent mass change at the Curie point. In the case of a TG apparatus capable of simultaneously conducting DSC and DTA, the same reference substances as those for DTA and DSC can be adopted.

2.3.2. Scale calibration and confirmation

The scale calibration for TG must be done by using reference masses for chemical balances and/or semimicrobalances in the appropriate range. This is called a primary scale calibration, and is performed under ordinary temperature and pressure when the apparatus is set up initially and periodically, thereafter.

In usual measurement by TG, scale calibration or confirmation is done by using Calcium Oxalate Monohydrate Reference Standard to take account of such effects as buoyancy and convection due to atmospheric gas flow in the real measurement state. This is called secondary scale calibration, and is performed under the standard operation conditions stated below by using the above-mentioned Reference Standard, with a certified water content. When the difference of water content between the measured value and the certified one for the Reference Standard is less than 0.3%, normal operation of the apparatus is confirmed. However, when the difference is more than 0.3%, scale calibration for TG must be done, based on the certified water content of the Reference Standard.

The standard operation conditions are as follows:

Amount of Calcium Oxalate Monohydrate Reference Standard: 10 mg

Heating rate: 5°C/min

Temperature range: from room temperature to 250°C

Atmospheric gas: dried Nitrogen or dried Air

Flow rate of atmospheric gas, hanging- or Roberval's-type balance: 40 mL/min

horizontal-type balance: 100 mL/min

2.4. Notes on operating conditions

In TG measurement, the following operation conditions must be recorded: sample size, heating rate, temperature range, kind and flow rate of atmospheric gas, etc.
2.53 Viscosity Determination

Viscosity Determination is a method to determine the viscosity of liquid samples using a viscometer.

When a liquid moves in a definite direction, and the liquid velocity has a gradient with respect to the direction rectangular to that of flow, a force of internal friction is generated along both sides of a hypothetical plane parallel to the movement. This flow property of a liquid is expressed in terms of viscosity. The internal friction per unit area on the parallel plane is called slip stress or shear stress, and the velocity gradient with respect to the direction rectangular to that of flow is called slip velocity or shear velocity. A liquid of which the slip velocity is proportional to its slip stress is called a Newtonian liquid. Since the viscosity of a liquid at a certain temperature and is called viscosity. The viscosity is expressed in the unit of meters squared per second (m²/s), and usually millimeters squared per second (mm²/s).

A liquid whose slip velocity is not proportional to its slip stress is called a non-Newtonian liquid. Since the viscosity of a sample of a non-Newtonian liquid changes with its slip velocity, the viscosity measured at a certain slip velocity is called an apparent viscosity. In that case, the value of slip velocity divided by the corresponding slip stress is called an apparent viscosity. Thus, the relationship between apparent viscosity and slip velocity will permit characterization of the flow properties of a given non-Newtonian liquid.

The value of the viscosity, η, divided by the density, ρ, at the same temperature is defined as a kinematic viscosity, ν, which is expressed in the unit of meters squared per second (m²/s), and usually millimeters squared per second (mm²/s).

The viscosity of a liquid is determined either by the following Method I or Method II.

1. Method I Viscosity measurement by capillary tube viscometer

For measuring the viscosity of a Newtonian liquid, a capillary tube viscometer is usually used, in which the downflowing time of a liquid, t (s), required for a definite volume of the liquid to flow through a capillary tube is measured and the kinematic viscosity, ν, is calculated according to the following equation:

\[ \nu = Kt \]

Further, the viscosity, η, is calculated from the next equation:

\[ \eta = \nu \rho = Kt \rho \]

where ρ (g/mL) is the density of the liquid measured at the same temperature, t (°C).

The parameter K (mm²/s) represents the viscometer constant and is previously determined by using the Standard Liquids for Calibrating Viscometers with known kinematic viscosity. In the case of a liquid having a similar viscosity to water, water itself can be used as a reference standard liquid for the calibration. The kinematic viscosity of water is 1.0038 mm²/s at 20°C. In the cases of liquids having a slightly higher viscosity than water, the Standard Liquids for Calibrating Viscometers should be used for the calibration.

The intrinsic viscosity, \([n]\) (dL/g), of a polymer solution is obtained by plotting the relation of viscosity versus concentration and extrapolating the obtained straight line to zero concentration. Intrinsic viscosity shows the degree of molecular expansion of a polymer substance in a given solvent (sample solution) and is also a measure of the average molecular mass of the polymer substance.

The downflowing time, t (s), for a polymer solution, whose concentration is \(c (g/dL)\), and \(t_0\) (s) for the solvent used for dissolving the polymer, are measured by using the same viscometer, and then the intrinsic viscosity of a given polymer substance, \([\eta]\), is calculated according to the following equation:

\[ [\eta] = \lim_{c \to 0} \frac{(t - t_0)}{c} - 1 \]

or

\[ [\eta] = \lim_{c \to 0} \frac{\ln \frac{t}{t_0}}{c} \]

When the concentration dependency of \(\frac{(t/t_0) - 1}{c}\) is not large, the value of \(\frac{(t/t_0) - 1}{c}\) at a concentration directed in the respective monograph can be assumed to be the intrinsic viscosity for a given substance.

Unless otherwise specified, the viscosity of a sample solution is measured with the following apparatus and procedure.

1.1. Apparatus

For measurement of the kinematic viscosity in the range of 1 to 100,000 mm²/s, the Ubbelohde-type viscometer illustrated in Fig. 2.53-1 can be used. The approximate relations between kinematic viscosity range and inside diameter of the capillary tube suitable for the measurement of various liquids with different viscosity, are given in Table 2.53-1. Although a capillary tube viscometer other than the Ubbelohde-type one specified in Table 2.53-1 can also be used, a viscometer should be selected in which the downflowing time, t (s), of a sample solution to be determined would be
between 200 s and 1000 s.

1.2. Procedure

Place a sample solution in a viscometer from the upper end of tube 1, so that the meniscus of the solution is at a level between the two marked lines of bulb A. Place the viscometer vertically in a thermostatted bath maintained at a specified temperature within ±0.1°C, until bulb C is fully immersed, and let it stand for about 20 minutes to attain the specified temperature. Close bulb C with a cork and pull the sample solution up to the middle part of tube 2, and stop the suction. Open the end of tube 3, and immediately close the end of tube 2. After confirming that the liquid column is cut off at the lowest end of the capillary tube, open the end of tube 2 to make the sample solution flow down through the capillary tube. Record the time, \( t \) (s), required for the meniscus of the sample solution to fall to the upper to the lower marked line of bulb B.

Determine the viscometer constant \( K \) previously, using the Standard Liquids for Calibrating Viscometers under the same conditions. The temperature at which the calibration is conducted must be identical with that specified in the monograph.

2. Method II Viscosity measurement by rotational viscometer

A rotational viscometer is usually used for measuring the viscosity of Newtonian or non-Newtonian liquids. The measuring principle of a rotational viscometer generally consists in the detection and determination of the force acting on a rotor (torque), when it rotates at a constant angular velocity in a liquid. The extent of torque generated by the rotation can be detected in terms of the torsion of a spring and the liquid viscosity is calculated from the scale-indicated value corresponding to the degree of torsion.

The viscosity of a sample solution is measured with the following apparatus and procedure.

2.1. Apparatus

Viscosity measurement is performed by using any one of the following three types of rotational viscometers.

2.1.1. Coaxial double cylinder-type rotational viscometer (Couette type viscometer)

In the coaxial double cylinder-type rotational viscometer, viscosity is determined by placing a liquid in the gap between the inner and the outer cylinders, which share the same central axis and rotate separately, and the generated torque acting on one cylinder surface when the other cylinder is rotated, and the corresponding angular velocity, are measured.

As shown in Fig. 2.53-2a, the inner cylinder is hung by a wire whose twist constant is designated as \( k \). In Fig. 2.53-2a, half the outer diameter of the inner cylinder and inner diameter of the outer cylinder are designated as \( R_i \) and \( R_o \), respectively, and the length of the inner cylinder immersed in a liquid is designated as \( l \). When a liquid is introduced into the gap between the two cylinders, and the outer cylinder is made to rotate at a constant angular velocity, \( \omega \), the inner cylinder is also forced to rotate due to the viscosity of the liquid. Consequently, torque, \( T \), is generated by the forced rotation in a viscous liquid, and in the steady state the torque is balanced by the torsion of the wire, as indicated by the degree of rotation \( \theta \). Then, the relationship can be expressed by \( T = k \theta \) and the viscosity of a liquid, \( \eta \), is determined from the following equation by measuring the relationship between \( \omega \) and \( \theta \). Conversely, viscosity measurement can also be performed by rotating the inner cylinder, and the same relationship holds.

\[
\eta = \frac{100T}{4\pi l\omega} \left( \frac{1}{R_i^2} - \frac{1}{R_o^2} \right)
\]

\( \eta \): viscosity of a liquid (mPa·s)
\( \pi \): circumference/diameter ratio
\( l \): length of the inner cylinder (cm)
\( \omega \): angular velocity (rad/s)
\( T \): torque acting on cylinder surface (10⁻⁷ N·m)
\( R_i \): 1/2 of outer diameter of the inner cylinder (cm)
\( R_o \): 1/2 of inner diameter of the outer cylinder (cm)

2.1.2. Single cylinder-type rotational viscometer (Brookfield type viscometer)

In the single cylinder-type rotational viscometer, viscosity is determined by measuring the torque acting on the cylinder
Fig. 2.53-2b  Single cylinder-type rotational viscometer

surface when the cylinder immersed in a liquid is rotated at a given angular velocity. Use an apparatus of the type illustrated in Fig. 2.53-2b. If the apparatus constant $K_B$ is previously determined experimentally by using the Standard Liquids for Calibrating Viscometers, the viscosity of a liquid, $\eta$, can be obtained from the following equation.

$$\eta = \frac{K_B T}{\omega}$$

where, $\eta$: viscosity of a liquid (mPa·s)  
$K_B$: apparatus constant of viscometer (rad/cm³)  
$\omega$: angular velocity (rad/s)  
$T$: torque acting on cylinder surface ($10^{-7}$ N·m)  

2.1.3. Cone-flat plate-type rotational viscometer (Cone-plate type viscometer)

In the cone-flat plate-type rotational viscometer, viscosity is determined by placing a liquid in the gap between a flat disc and a cone with a large vertical angle sharing the same rotational axis, and the torque and the corresponding angular velocity are measured, when either the disc or the cone is rotated in a viscous liquid.

As shown in Fig. 2.53-2c, a liquid is introduced to fill the gap between a flat disc and a cone forming an angle $\alpha$ (rad). When either the flat disc or the cone is rotated at a constant angular velocity or a constant torque, the torque acting on the disc or cone surface rotated by the viscous flow and the corresponding angular velocity in the steady state, are measured. The viscosity of the liquid, $\eta$, can be calculated from the following equation.

$$\eta = \frac{3\pi}{2\pi R^3} \cdot \frac{100T}{\omega}$$

$\eta$: viscosity of a liquid (mPa·s)  
$\pi$: circumference/diameter ratio  
$R$: radius of cone (cm)  
$\alpha$: angle between flat disc and cone (rad)  
$\omega$: angular velocity (rad/s)  
$T$: torque acting on flat disc or cone surface ($10^{-7}$ N·m)  

2.2. Procedure

Set up the viscometer so that its rotational axis is perpendicular to the horizontal plane. Place a sufficient quantity of a sample solution in the viscometer, and allow the measuring system to stand until a specified temperature is attained, as directed in the monograph. Where it is desired to measure the viscosity within a precision of 1%, measuring temperature should be controlled within 0.1°C. Next, after confirming that the sample solution is at the designated temperature, start operating the rotational viscometer. After the forced rotation induced by the viscous flow has reached a steady state and the indicated value on the scale, which corresponds to the rotational frequency or the torque, has become constant, read the value on the scale. Then, calculate the viscosity $\eta$ by using the respective equation appropriate to the type of viscometer being used. Determination or confirmation of the apparatus constant should be conducted beforehand by using the Standard Liquids for Calibrating Viscometers, and the validation of the apparatus and operating procedures should also be performed by using those standard liquids.

In the case of a non-Newtonian liquid, repeat the procedure for measuring the viscosity of the liquid with variation of the rotation velocity or torque from one measurement to another. From a series of such viscosity measurements, the relationship between the slip velocity and the slip stress of a non-Newtonian liquid, i.e., the flow characteristics of a non-Newtonian liquid, can be obtained.

Calibration of a rotational viscometer is conducted by using water and the Standard Liquids for Calibrating Viscometers. These standard liquids are used for the determination or confirmation of the apparatus constant of the rotational viscometer. They are also used for periodic recalibration of the viscometer to confirm maintenance of a specified precision.

2.54 pH Determination

pH is defined as the reciprocal of the common logarithm of hydrogen ion activity, which is the product of hydrogen ion concentration and the activity coefficient. Conventionally it is used as a scale of hydrogen ion concentration of a sample solution.

pH of a sample solution is expressed by the following equation in relation to the pH of a standard solution (pHs), and can be measured by a pH meter using a glass electrode.

$$\text{pH} = \text{pHs} + \frac{E - E_s}{2.3026\frac{RT}{F}}$$
pHs: pH value of a pH standard solution.

$E$: Electromotive force (volt) induced on the following galvanic cell composed of a glass electrode and suitable reference electrode in a sample solution:

Glass electrode | sample solution | reference electrode

$E$: Electromotive force (volt) induced on the following galvanic cell composed of a glass electrode and suitable reference electrode in a pH standard solution:

Glass electrode | standard pH solution | reference electrode

$R$: Gas constant

$T$: Absolute temperature

$F$: Faraday’s constant

The value of 2.3026 $RT/F$ (V) in the above equation means the degree of electromotive force (V) per one pH unit and it is dependent on the temperature as shown in Table 2.54-1:

### 1. pH Standard Solution

The pH standard solutions are used as a standard of pH, for standardization of a pH meter. To prepare the pH standard solutions, use distilled water or water with a conductivity not more than 0.50 mg/L, boiled for not less than 15 minutes and cooled in a container fitted with a carbon dioxide-absorbing tube. Since the pH may change gradually during storage over a long period, it is necessary to ascertain whether the expected pH value is held or not by comparison with newly prepared standard, when the solution is used after long storage.

(i) Oxalate pH standard solution—Pulverize potassium trihydrogen dioxalate dihydrate for pH determination, and dry in a desiccator (silica gel). Weigh 12.71 g (0.05 mole) of it accurately, and dissolve in water to make exactly 1000 mL.

(ii) Phthalate pH standard solution—Pulverize potassium phthalate for pH determination, and dry at 110°C to constant mass. Weigh 10.21 g (0.05 mole) of it accurately, and dissolve in water to make exactly 1000 mL.

(iii) Phosphate pH standard solution—Pulverize potassium dihydrogen phosphate for pH determination and disodium hydrogen phosphate for pH determination, and dry at 110°C to constant mass. Weigh 3.40 g (0.025 mole) of potassium dihydrogen phosphate and 3.55 g (0.025 mole) of disodium hydrogen phosphate accurately, and dissolve in water to make exactly 1000 mL.

(iv) Borate pH standard solution—Allow sodium tetraborate for pH determination to stand in a desiccator (saturated sodium bromide aqueous solution) until it reaches constant mass. Weigh 3.81 g (0.01 mole) of it accurately, and dissolve in water to make exactly 1000 mL.

(v) Carbonate pH standard solution—Dry sodium hydrogen carbonate for pH determination in a desiccator (silica gel) to constant mass, and weigh 2.10 g (0.025 mole) of it accurately. Dry sodium carbonate for pH determination between 300°C and 500°C to constant mass, and weigh 2.65 g (0.025 mole) of it accurately. Dissolve both reagents in water to make exactly 1000 mL.

(vi) Calcium hydroxide pH standard solution—Reduce calcium hydroxide for pH determination to a fine powder, transfer 5 g to a flask, add 1000 mL of water, shake well, and allow the solution to become saturated at a temperature between 23°C and 27°C. Then filter the supernatant at the same temperature and use the clear filtrate (about 0.02 mol/L).

The pH values of these pH standard solutions at various temperatures are shown in the Table below. pH values at an arbitrary temperature not indicated in Table 2.54-2 can be calculated by the interpolation method.

### 2. Apparatus

A pH meter generally consists of an electrode system of a glass electrode and a reference electrode, an amplifier and an indicating unit for controlling the apparatus and for displaying the measured value of electromotive force. The indicating unit is usually fitted with dials for zero and span (sensitivity) adjustment. Sometimes a temperature compensation dial is included.

The reproducibility of a pH meter should be within 0.05 pH unit, when measurements for an arbitrary pH standard solution are repeated five times, following the procedure described below. After each measurement it is necessary to wash the detecting unit well with water.

### 3. Procedure

Immerse the glass electrode previously in water for more than several hours. Start the measurement after confirming stable running of the apparatus. Rinse well the detecting unit with water, and remove the remaining water gently with a piece of filter paper.

</table>
To standardize the pH meter, two pH standard solutions are usually used as follows. Immers the detection unit in the phosphate pH standard solution and adjust the indicated pH to the pH value shown in the Table. Next, immerse the detection system in the second pH standard solution, which should be selected so that the expected pH of the sample solution to be determined is between the pH values of the two pH standard solutions, and measure the pH under the same conditions as used for the first pH standard solution. Adjust the indicated pH to the defined pH value using the span adjustment dial, when the observed pH is not identical with that tabulated. Repeat the above standardization procedure until both pH standard solutions give observed pH values within 0.02 pH unit of the tabulated value without further adjustments. When a pH meter is fitted with a temperature compensation dial, the standardization procedure is done after the setting of the temperature to that of the pH standard solution to be measured.

In the case of using an apparatus having an auto-calibration function, it is necessary to confirm periodically that the pH values of two pH standard solutions are identical with the tabulated values within 0.05 pH unit.

After finishing the standardization procedure described above, rinse well the electrodes with water, remove the attached water using a filter paper, immerse the electrode system in the sample solution, and read the indicated pH value after confirming the value is stable. If necessary, a sample solution can be agitated gently.

In the pH determination, the temperature of a sample solution must be controlled to be the same as that of the pH standard solutions with which the pH meter was standardized (within 2°C). When a sample solution is alkaline, the measurement should be done in a vessel with a cover and if necessary, in a stream of inert gas such as nitrogen. Furthermore, for a strongly alkaline solution above pH 11 containing alkali metal ions, an alkali error may be induced in the pH measurement. Thus, in such a case, an electrode with less alkali error should be used and an appropriate correction should be applied to the measured value.

4. Note
Construction and treatment in detail are different for different pH meters.

### 2.55 Vitamin A Assay

Vitamin A Assay is a method to determine vitamin A in Retinol Acetate, Retinol Palmitate, Vitamin A Oil, Cod Liver Oil and other preparations. Method 1 is for the assay of synthetic vitamin A esters, using the ultraviolet-visible spectrophotometry (Method 1-1) or the liquid chromatography (Method 1-2). Method 2 is for the assay of vitamin A of natural origin, containing many geometrical isomers, using the ultraviolet-visible spectrophotometry to determine vitamin A as vitamin A alcohol obtained by saponification in an alkaline solution and extraction.

One Vitamin A Unit (equal to 1 vitamin A I.U.) is equivalent to 0.300 µg of vitamin A (all-trans vitamin A alcohol).

1. Procedure
All procedures should be carried out quickly and care should be taken as far as possible to avoid exposure to light, air, oxidants, oxidizing catalysts (e.g. copper, iron), acids and heat. If necessary, light-resistant vessels may be used.

Generally, for synthetic vitamin A esters apply Method 1-1 or Method 1-2, but if the assay conditions required for Method 1-1 are not suitable, apply Method 2.

#### 1. Method 1-1
Weigh accurately about 0.1 g of the sample, and dissolve in 2-propanol for vitamin A assay to make exactly 50 mL. Dilute this solution with 2-propanol for vitamin A assay to make a solution so that each mL contains 10 to 15 vitamin A Units, and use this solution as the sample solution. Determine the absorption spectrum of the sample solution between 220 nm and 400 nm as directed under Ultraviolet-visible Spectrophotometry to obtain the wavelength of the maximum absorption and the absorbances at 300 nm, 310 nm, 320 nm, 326 nm, 330 nm, 340 nm and 350 nm. When the maximum absorption lies between 325 nm and 328 nm, and the ratios, $A_{326}/A_{328}$, of each absorbance, $A_{326}$ at 300 nm, 310 nm, 320 nm, 330 nm, 340 nm and 350 nm to the absorbance, $A_{326}$ at 326 nm are within the range of ±0.030 of the values in the Table, the potency of vitamin A in Units per g of the sample is calculated from the following equation.

$$
\text{Units of vitamin A in 1 g} = \frac{A_{326}}{M} \times \frac{V}{100} \times 1900
$$

$A_{326}$: Absorbance at 326 nm
$V$: Total volume (mL) of the sample solution
$M$: Amount (g) of sample in V mL of the sample solution
1900: Conversion factor from specific absorbance of retinol ester to IU (Unit/g)

This method is applied to drugs or preparations containing vitamin A esters (retinol acetate or retinol palmitate) as the main component. However, when the wavelength of maximum absorption does not lie between 325 nm and 328 nm, or when the absorbance ratio $A_{326}/A_{328}$ is not within the range of ±0.030 of the values in Table 2.55-1, apply Method 2.

#### 1.2. Method 1-2
Proceed with an appropriate amount of sample as directed under Liquid Chromatography.

For the assay of retinol acetate and retinol palmitate use Retinol Acetate Reference Standard and Retinol Palmitate Reference Standard, respectively, and fix appropriately the operating procedure, the operating conditions and the system suitability based on the characteristics of the substance to be tested and the species and amount of coexisting substances.

1.3. Method 2

Unless otherwise specified, weigh accurately a sample con-
2.56 Determination of Specific Gravity and Density / General Tests

The density \( \rho \) (g/mL or g/cm\(^3\)) means the mass per unit volume, and the relative density means the ratio of the mass of a sample specimen to that of an equal volume of a standard substance. The relative density is also called the specific gravity.

The specific gravity, \( d' \), means the ratio of the mass of the sample specimen at \( t \)°C to that of an equal volume of water (H\(_2\)O) at \( t \)°C. Unless otherwise specified, the measurement is to be performed by Method 1, Method 2 or Method 4. When the specified value is accompanied with the term “about” in the monograph, Method 3 is also available.

1. Method 1. Measurement using a pycnometer

A pycnometer is a glass vessel with a capacity of usually 10 mL to 100 mL, having a ground-glass stopper fitted with a thermometer, and a side inlet-tube with a marked line and a ground-glass cap.

Weigh a pycnometer, previously cleaned and dried, to determine its mass \( M \). Remove the stopper and the cap. Fill the pycnometer with the sample solution, keeping them at a slightly lower temperature by 1°C to 3°C than the specified temperature \( t \)°C, and stopper them, taking care not to leave bubbles. Raise the temperature gradually, and when the thermometer shows the specified temperature, remove the portion of the sample solution above the marked line through the side tube, cap the side tube, and wipe the outside surface thoroughly. Measure the mass \( M_t \) of the pycnometer filled with the sample solution. Perform the same procedure, using the same pycnometer containing water, and note the mass \( M_z \) at the specified temperature \( t \)°C.

The specific gravity \( d' \) can be calculated by use of the following equation.

\[
d' = \frac{M_t - M}{M_z - M}
\]

Further, when measurements for a sample solution and water are performed at the same temperature \( t \)°C, the density of the sample solution at the temperature \( t \)°C \((\rho_t)\) can be calculated from the measured specific gravity \( d' \) and the density of water at the temperature \( t \)°C \((\rho_0)\) indicated in Table 2.56-1 by using the following equation.

\[
\rho_t = \rho_0 d'
\]

A Sprengel-Ostwald pycnometer is a glass vessel with a capacity of usually 1 mL to 10 mL. As shown in Fig. 2.56-1, both ends are thick-walled fine tubes (inside diameter: 1-

* In this Table, although the unit of density is represented by g/mL in order to harmonize with the unit expression in the text, it should be expressed in g/cm\(^3\) seriously.
Take the pycnometer out of the water bath, wipe thoroughly and then, by attaching a piece of filter paper to the end of B, sample solution is performed at the same temperature. Attach a hydrometer, the reading must be in accordance with the instructions. Further, when measurements of specific gravity for a sample solution and water are performed at the same temperature $t^\circ C$, the density of sample solution at temperature $t^\circ C$ can be calculated by using the equation described in Method 1.

Further, when measurements of specific gravity for a sample solution and water are performed at the same temperature ($t^\circ C = r^\circ C$), the density of sample solution at temperature $t^\circ C$ can be calculated by using the equation described in Method 1.

Clean a hydrometer with ethanol (95) or diethyl ether. Stir the sample well with a glass rod, and float the hydrometer in the well. When the temperature is adjusted to the specified temperature $t^\circ C$ and the hydrometer comes to a standstill, read the specific gravity $d'_i$ or the density $\rho'_i$ at the upper brim of the meniscus. Here the temperature $t^\circ C$ indicates the temperature at which the hydrometer is calibrated. If specific instructions for reading the meniscus are supplied with the hydrometer, the reading must be in accordance with the instructions.

Further, when measurement of the specific gravity for a sample solution is performed at the same temperature ($t^\circ C = t^\circ C$), at which the hydrometer is calibrated, the density of a sample solution at $t^\circ C$, $\rho'_i$, can be calculated by using the specific gravity $d'_i$ and the equation shown in Method 1.

Density measurement with an oscillator-type density meter is a method for obtaining the density of liquid or gas by measuring the intrinsic vibration period $T$ (s) of a glass tube cell filled with sample specimen. When a glass tube containing a sample is vibrated, it undergoes a vibration with an intrinsic vibration period $T$ in proportion to the mass of the sample specimen. If the volume of the vibrating part of the sample cell is fixed, the relation of the square of intrinsic oscillation period and density of the sample specimen shall be linear.

Before measuring a sample density, the respective intrinsic oscillation periods $T_{S1}$ and $T_{S2}$ for two reference substances (density: $\rho_{S1}$, $\rho_{S2}$) must be measured at a specified temperature $t^\circ C$, and the cell constant $K_r$ (g cm$^{-3}$ s$^{-2}$) must be determined by using the following equation.

$$K_r = \frac{\rho'_{S1} - \rho'_{S2}}{T_{S1}^2 - T_{S2}^2}$$

Usually, water and dried air are chosen as reference substances. Here the density of water at $t^\circ C$, $\rho'_{S1}$, is taken from Table 2.56-1, and that of dried air $\rho'_{S2}$ is calculated by using the following equation, where the pressure of dried air is at $p$ kPa.

$$\rho'_{S2} = 0.0012932 \times \{273.15/(273.15 + t')\} \times (p/101.325)$$

Next, introduce a sample specimen into a sample cell having a cell constant $K_s$, the intrinsic vibration period, $T_s$, for the sample under the same operation conditions as employed for the reference substances. The density of a sample specimen at $t^\circ C$, $\rho'_s$, is calculated by use of the following equation, by introducing the intrinsic oscillation period $T_{S1}$ and the density of water at a specified temperature $t^\circ C$, $\rho'_{S1}$, into the equation.

$$\rho'_s = \rho'_{S1} + K_r (T_{S1}^2 - T_s^2)$$

Further, the specific gravity of a sample specimen $d'_s$ against water at a temperature $t^\circ C$ can be obtained by using the equation below, by introducing the density of water at a temperature $t^\circ C$, $\rho'_{S1}$, indicated in Table 2.56-1.

$$d'_s = \frac{\rho'_s}{\rho'_{S1}}$$

4.1. Apparatus
An oscillator-type density meter is usually composed of a glass tube cell of about 1 mL capacity, the curved end of which is fixed to the vibration plate, an oscillator which ap-
2.57 Boiling Point and Distilling Range Test

The boiling point and distilling range are determined by Method 1 or Method 2 as described herein, unless otherwise specified. Boiling point is the temperature shown between the first 5 drops of distillate leave the tip of the condenser and when the last liquid evaporates from the bottom of the flask. Distilling range test is done to determine the volume of the distillate which has been collected in the range of temperature directed in the monograph.

1. Method 1 This method is applied to a sample for which the permissible range of boiling temperature is smaller than 5°C.

1.1. Apparatus

Use the apparatus illustrated in Fig. 2.57-1.

1.2. Procedure

Measure 25 mL of the sample, whose temperature is previously noted, using a volumetric cylinder graduated in 0.1 mL, and transfer it to a distilling flask A of 50- to 60-mL capacity. Use this cylinder as the receiver for the distillate without rinsing out any of the adhering liquid. Put boiling chips into the distilling flask A, insert a thermometer B with an immersion line so that its immersion line C is on a level with the lower end of cork stopper D and the upper end of its mercury bulb is located in the center of the delivery tube, and connect condenser E with the distilling flask A and adapter F with the condenser E. Insert the open end of F into the mouth of cylinder G (receiver) so that air can pass through slightly. Use a hood with a height sufficient to shield A, and heat A with a suitable heat source. When direct flame is applied as the heat source, put A on a hole of a fire-resistant, heat-insulating board [a board consisting of a fire-resistant, heat-insulating material, 150 mm square and about 6 mm thick (or a wire gauge of 150 mm square bonded to fire-resistant, heat-insulation materials in about 6 mm thickness), having an its center a round hole 30 mm in diameter].

Unless otherwise specified, distill the liquid sample by the application of heat, at a rate of 4 to 5 mL per minute of distillate in the case of liquids whose boiling temperature to be determined is lower than 200°C and at a rate of 3 to 4 mL per minute in the case of liquids whose boiling temperature is 200°C or over, and read the boiling point. For the distilling range test, bring the temperature of distillate to the temperature at which the volume was originally measured, and measure the volume of distillate.

Liquids that begin to distill below 80°C are cooled to between 10°C and 15°C before measuring the volume, and the receiving cylinder is kept immersed in ice up to a point 25 mm from the top during the distillation.

Correct the observed temperature for any variation in the barometric pressure from the normal (101.3 kPa), by allowing 0.1 degree for each 0.36 kPa of variation, adding if the pressure is lower, or subtracting if higher than 101.3 kPa.

2. Method 2 This method is applied to the sample for which the permissible range of boiling temperature is 5°C or more.

2.1. Apparatus

The same apparatus as described in Method 1 is used. However, use a 200-mL distilling flask A with a neck 18 to 24 mm in inside diameter having a delivery tube 5 to 6 mm in inside diameter. The fire-resistant, heat-insulating board used for direct flame heating should have in its center a round hole 50 mm in diameter.
2.2. Procedure
Measure 100 mL of the sample, whose temperature is previously noted, using a volumetric cylinder graduated in 1 mL, and carry out the distillation in the same manner as in Method 1.

2.58 X-Ray Powder Diffraction Method

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia. The parts of the text that are not harmonized are marked with symbols (*). *X-Ray Powder Diffraction Method is a method for measuring characteristic X-ray diffraction angles and intensities from randomly oriented powder crystallites irradiated by a monochromated X-ray beam.

Every crystalline phase of a given substance produces a characteristic X-ray diffraction pattern. Diffraction patterns can be obtained from a randomly oriented crystalline powder composed of crystallites or crystal fragments of finite size. Essentially 3 types of information can be derived from a powder diffraction pattern: angular position of diffraction lines (depending on geometry and size of the unit cell); intensities of diffraction lines (depending mainly on atom type and arrangement, and particle orientation within the sample); and diffraction line profiles (depending on instrumental resolution, crystallite size, strain and specimen thickness).

Experiments giving angular positions and intensities of lines can be used for applications such as qualitative phase analysis (for example, identification of crystalline phases) and quantitative phase analysis of crystalline materials. An estimate of the amorphous and crystalline fractions(1) can also be made. The X-ray powder diffraction (XRPD) method provides an advantage over other means of analysis in that it is usually non-destructive in nature (specimen preparation is usually limited to grinding to ensure a randomly oriented sample). XRPD investigations can also be carried out under in situ conditions on specimens exposed to non-ambient conditions, such as low or high temperature and humidity.

1. Principle
X-ray diffraction results from the interaction between X-rays and electron clouds of atoms. Depending on the atomic arrangement, interferences arise from the scattered X-rays. These interferences are constructive when the path difference between 2 diffracted X-ray waves differs by an integral number of wavelengths. This selective condition is described by the Bragg equation, also called Bragg’s law (see Fig. 2.58-1)

\[ 2d_{hkl} \sin \theta_{hkl} = n \lambda \]

The wavelength \( \lambda \) of the X-rays is of the same order of magnitude as the distance between successive crystal lattice planes, or \( d_{hkl} \) (also called ‘d-spacings’). \( \theta_{hkl} \) is the angle between the incident ray and the family of lattice planes, and \( \sin \theta_{hkl} \) is inversely proportional to the distance between successive crystal planes or d-spacings.

The direction and spacing of the planes with reference to the unit cell axes are defined by the Miller indices \([hkl]\). These indices are the reciprocals, reduced to the next-lower integer, of the intercepts that a plane makes with the unit cell axes. The unit cell dimensions are given by the spacings, \( a, b \) and \( c \) and the angles between them, \( \alpha, \beta \) and \( \gamma \). The interplanar spacing for a specified set of parallel \( hkl \) planes is denoted by \( d_{hkl} \). Each such family of planes may show higher orders of diffraction where the \( d \) values for the related families of planes, \( nh, nk, nl \) are diminished by the factor \( 1/n \) (\( n \) being an integer: \( 2,3,4, \) etc.). Every set of planes throughout a crystal has a corresponding Bragg diffraction angle, \( \theta_{hkl} \), associated with it (for a specific wavelength \( \lambda \)).

A powder specimen is assumed to be polycrystalline so that at any angle \( \theta_{hkl} \) there are always crystallites in an orientation allowing diffraction according to Bragg’s law(2). For a given X-ray wavelength, the positions of the diffraction peaks (also referred to as ‘lines’, ‘reflections’ or ‘Bragg reflections’) are characteristic of the crystal lattice (d-spacings), their theoretical intensities depend on the crystallographic unit cell content (nature and positions of atoms), and the line profiles on the perfection and extent of the crystal lattice. Under these conditions the diffraction peak has a finite intensity arising from atomic arrangement, type of atoms, thermal motion and structural imperfections, as well as from instrument characteristics. The intensity is dependent upon many factors such as structure factor, temperature factor, crystallinity, polarization factor, multiplicity and Lorentz factor. The main characteristics of diffraction line profiles are at position, peak height, peak area and shape (characterized by, for example, peak width or asymmetry, analytical function, empirical representation). An example of the type of powder patterns obtained for 5 different solid phases of a substance are shown in Fig. 2.58-2.

In addition to the diffraction peaks, an X-ray diffraction experiment also generates a more-or-less uniform background, upon which the peaks are superimposed. Besides specimen preparation, other factors contribute to the background, for instance the sample holder, diffuse scattering from air and equipment, other instrumental parameters such as detector noise, general radiation from the X-ray tube, etc. The peak to background ratio can be increased by minimizing background and by choosing prolonged exposure times.
2. Instrument
2.1. Instrument set-up

X-ray diffraction experiments are usually performed using powder diffractometers or powder cameras. A powder diffractometer generally comprises 5 main parts: an X-ray source; incident beam optics, which may perform monochromatization, filtering, collimation and/or focusing of the beam; a goniometer; diffraction beam optics, which may perform monochromatization, filtering, collimation and focusing or parallelising of the beam; and a detector. Data collection and data processing systems are also required and are generally included in current diffraction measurement equipment.

Depending on the type of analysis to be performed (phase identification, quantitative analysis, lattice parameters determination, etc.), different XRPD instrument configurations and performance levels are required. The simplest instruments used to measure powder patterns are powder cameras. Replacement of photographic film as the detection method by photon detectors has led to the design of diffractometers in which the geometric arrangement of the optics is not truly focusing but parafocusing, such as in the Bragg-Brentano geometry. The Bragg-Brentano parafocusing configuration is currently the most widely used and is therefore briefly described here.

A given instrument may provide a horizontal or vertical \( \theta/2\theta \) geometry or a vertical \( \theta/\theta \) geometry. For both geometries, the incident X-ray beam forms an angle \( \theta \) with the specimen surface plane and the diffracted X-ray beam forms an angle \( 2\theta \) with the direction of the incident X-ray beam (an angle \( 0 \) with the specimen surface plane). The basic geometric arrangement represented in Fig. 2.58-3. The divergent beam of radiation from the X-ray tube (the so-called ‘primary beam’) passes through the parallel plate collimators and a divergence slit assembly and illuminates the flat surface of the specimen. All the rays diffracted by suitably oriented crystallites in the specimen at an angle \( 2\theta \) converge to a line at the receiving slit. A second set of parallel plate collimators and a scatter slit may be placed either behind or before the receiving slit. The axes of the line focus and of the receiving slit are at equal distances from the axis of the goniometer. The X-ray quanta are counted by a radiation detector, usually a scintillation counter, a sealed-gas proportional counter, or a position-sensitive solid-state detector such as imaging plate or CCD detector. The receiving slit assembly and the detector are coupled together and move tangentially to the focusing circle. For \( \theta/2\theta \) scans the goniometer rotates the specimen about the same axis as that of the detector, but at half the rotational speed, in \( \theta/2\theta \) motion. The surface of the specimen thus remains tangential to the focusing circle. The parallel plate collimator limits the axial divergence of the beam and hence partially controls the shape of the diffracted line profile.

A diffractometer may also be used in transmission mode. The advantage with this technology is to lessen the effects due to preferred orientation. A capillary of about 0.5 – 2 mm thickness can also be used for small sample amounts.

2.2. X-ray radiation

In the laboratory, X-rays are obtained by bombarding a metal anode with electrons emitted by the thermionic effect and accelerated in a strong electric field (using a high-voltage generator). Most of the kinetic energy of the electrons is converted to heat, which limits the powder of the tubes and
requires efficient anode cooling. A 20- to 30-fold increase in brilliance can be obtained using rotating anodes and by using X-ray optics. Alternatively, X-ray photons may be produced in a large-scale facility (synchrotron).

The spectrum emitted by an X-ray tube operating at sufficient voltage consists of a continuous background of polychromatic radiation and additional characteristic radiation that depends on the type of anode. Only this characteristic radiation is used in X-ray diffraction experiments. The principal radiation sources utilized for X-ray diffraction are vacuum tubes utilizing copper, molybdenum, iron, cobalt or chromium as anodes; copper, molybdenum or cobalt X-rays are employed most commonly for organic substances (the use of cobalt anodes can be especially preferred to separate distinct X-ray lines). The choice of radiation to be used depends on the absorption characteristics of the specimen and possible fluorescence by atoms present in the specimen. The wavelengths used in powder diffraction generally correspond to the Kα radiation from the anode. Consequently, it is advantageous to make the X-ray beam ‘monochromatic’ by eliminating all the other components of the emission spectrum. This can be partly obtained using Kα filters, i.e. metal filters selected as having an absorption edge between the Kα and Kβ wavelengths emitted by the tube.

Such a filter is usually inserted between the X-ray tube and the specimen. Another, more-and-more-commonly used way to obtain a monochromatic X-ray beam is via a large monochromator crystal (usually referred to as a ‘monochromator’). This crystal is placed before or behind the specimen and diffracts the different characteristic peaks of the X-ray beam (i.e. Kα and Kβ) at different angels, so that only one of them may be selected to enter into the detector. It is even possible to separate Kα1 and Kα2 radiations by using a specialized monochromator. Unfortunately, the gain in getting a monochromatic beam by using a filter or a monochromator is counteracted by a loss in intensity. Another way of separating Kα and Kβ wavelengths is by using curved X-rays mirrors that can simultaneously monochromate and focus or parallelize the X-ray beam.

2.3. Radiation protection

Exposure of any part of the human body to X-rays can be injurious to health. It is therefore essential that whenever X-ray equipment is used, adequate precautions are taken to protect the operator and any other person in the vicinity. Recommended practice for radiation protection as well as limits for the levels of X-radiation exposure are those established by national legislation in each country. If there are no official regulations or recommendations in a country, the latest recommendations of the International Commission on Radiological Protection should be applied.

3. Specimen preparation and mounting

The preparation of the powdered material and mounting of the specimen in a suitable holder are critical steps in many analytical methods, and are particularly so for X-ray powder diffraction analysis, since they can greatly affect the quality of the data to be collected. The main sources of error due to specimen preparation and mounting are briefly discussed here for instruments in Bragg-Brentano parafocusing geometry.

3.1. Specimen preparation

In general, the morphology of many crystalline particles tends to give a specimen that exhibits some degree of preferred orientation in the specimen holder. This is particularly evident for needle-like or plate-like crystals when size reduction yields finer needles or platelets. Preferred orientation in the specimen influences the intensities of various reflections, so that some are more intense and others are less intense, compared to what would be expected from a completely random specimen. Several techniques can be employed to improve randomness in the orientation of crystallites (and therefore to minimize preferred orientation), but further reduction of particle size is often the best and simplest approach. The optimum number of crystallites depends on the diffractometer geometry, the required resolution and the specimen attenuation of the X-ray beam. In some cases, particle sizes as large as 50 μm will provide satisfactory results in phase identification. However, excessive milling (crystallite sizes less than approximately 0.5 μm) may cause line broadening and significant changes to the sample itself such as:

(i) specimen contamination by particles abraded from the milling instruments (mortar, pestle, balls, etc.);
(ii) reduced degree of crystallinity;
(iii) solid-state transition to another polymorph;
(iv) chemical decomposition;
(v) introduction of internal stress;
(vi) solid-state reactions.

Therefore, it is advisable to compare the diffraction pattern of the non-ground specimen with that corresponding to a specimen of smaller particle size (e.g. a milled specimen). If the X-ray powder diffraction pattern obtained is of adequate quality considering its intended use, then grinding may not be required. It should be noted that if a sample contains more than one phase and if sieving is used to isolate particles to a specific size, the initial composition may be altered.

4. Control of the instrument performance

Goniometers and the corresponding incident and diffracted X-ray beam optics have many mechanical parts that need adjustment. The degree of alignment or misalignment directly influences the quality of the results of an XRPD investigation. Therefore, the different components of the diffractometer must be carefully adjusted (optical and mechanical systems, etc.) to adequately minimize systematic errors, while optimizing the intensities received by the detector. The search for maximum intensity and maximum resolution is always antagonistic when aligning a diffractometer. Hence, the best compromise must be sought whilst performing the alignment procedure. There are many different configurations and each supplier’s equipment requires specific alignment procedures.

The overall diffractometer performance must be tested and monitored periodically using suitable certified reference materials. Depending on the type of analysis, other well-defined reference materials may also be employed, although the use of certified reference materials is preferred.

5. Qualitative phase analysis (Identification of phases)

The identification of the phase composition of an unknown sample by XRPD is usually based on the visual or computer-assisted comparison of a portion of its X-ray diffraction powder pattern to the experimental or calculated pattern of a reference material. Ideally, these reference patterns are collected on well-characterized single-phase specimens. This approach makes it possible in most cases to identify a crystalline substance by its 2θ diffraction angles or d-
spacings and by its relative intensities. The computer-aided comparison of the diffraction pattern of the unknown sample to the comparison data can be based either on a more-or-less extended 2θ-range of the whole diffraction pattern or on a set of reduced data derived from the pattern. For example, the list of d-spacings and normalized intensities \( I_{\text{norm}} \), a so-called \((d, I_{\text{norm}})\)-list extracted from the pattern, is the crystallographic fingerprint of the material, and can be compared to \((d, I_{\text{norm}})\)-lists of single-phase samples compiled in databases.

For most organic crystals, when using Cu Kα radiation, it is appropriate to record the diffraction pattern in a 2θ-range from near 0° to possibly to at least 40°. The agreement in the 2θ-diffraction angles between specimen and reference is within 0.2° for the same crystal form, while relative intensities between specimen and reference may vary considerably due to preferred orientation effects. By their very nature, variable hydrates and solvates are recognized to have varying unit cell dimensions and as such shifting occurs in peak positions of the measured XRPD patterns for these materials. In these unique materials, variance in 2θ-positions of greater than 0.2° is not unexpected. As such, peak position variances such as 0.2° are not applicable to these materials. For other types of samples (e.g. inorganic salts), it may be necessary to extend the 2θ-region scanned to well beyond 40°. It is generally sufficient to scan past the 10 strongest reflections identified in single phase X-ray powder diffraction database files.

It is sometimes difficult or even impossible to identify phases in the following cases:

(i) non-crystallized or amorphous substances;
(ii) the components to be identified are present in low mass fractions of the analyte amounts (generally less than 10 per cent \(m/m\));
(iii) pronounced preferred orientation effects;
(iv) the phase has not been filed in the database used;
(v) formation of solid solutions;
(vi) presence of disordered structures that alter the unit cell;
(vii) the specimen comprises too many phases;
(viii) presence of lattice deformations;
(ix) structural similarity of different phases.

6. Quantitative phase analysis

If the sample under investigation is a mixture of 2 or more known phases, of which not more than 1 is amorphous, the percentage (by volume or by mass) of each crystalline phase and of the amorphous phase can, in many cases, be determined. Quantitative phase analysis can be based on the integrated intensities, on the peak heights of several individual diffraction lines\(^6\), or on the full pattern. These integrated intensities, peak heights or full-pattern data points are compared to the corresponding values of reference materials. These reference materials shall be single-phase or a mixture of known phases. The difficulties encountered during quantitative analysis are due to specimen preparation (the accuracy and precision of the results require in particular homogeneity of all phases and a suitable particle size distribution in each phase) and to matrix effects. In favorable cases, amounts of crystalline phases as small as 10 per cent may be determined in solid matrices.

6.1. Polymorphic samples

For a sample composed of 2 polymorphic phases \(a\) and \(b\), the following expression may be used to quantify the fraction \(F_a\) of phase \(a\):

\[
F_a = \frac{1}{1 + K(I_a/I_b)}
\]

The fraction is derived by measuring the intensity ratio between the 2 phases, knowing the value of the constant \(K\). \(K\) is the ratio of the absolute intensities of the 2 pure polymorphic phases \(I_a/I_b\). Its value can be determined by measuring standard samples.

6.2. Methods using a standard

The most commonly used methods for quantitative analysis are:

– the ‘external standard method’;
– the ‘internal standard method’;
– the ‘spiking method’ (often also called the ‘standard addition method’).

The ‘external standard method’ is the most general method and consists of comparing the X-ray diffraction pattern of the mixture, or the respective line intensities, with those measured in a reference mixture or with the theoretical intensities of a structural model, if it is fully known.

To limit errors due to matrix effects, an internal reference material is compared to the sample. With a diffraction pattern that does not overlap at all that of the sample to be analyzed, can be used. A known quantity of this reference material is added to the sample to be analyzed and to each of the reference mixtures. Under these conditions, a linear relationship between line intensity and concentration exists. This application, called the ‘internal standard method’, requires a precise measurement of diffraction intensities.

In the ‘spiking method’ (or ‘standard addition method’), some of the pure phase \(a\) is added to the mixture containing the unknown concentration of \(a\). Multiple additions are made to prepare an intensity-versus-concentration plot in which the negative \(x\) intercept is the concentration of the phase \(a\) in the original sample.

7. Estimate of the amorphous and crystalline fractions

In a mixture of crystalline and amorphous phases, the crystalline and amorphous fractions can be estimated in several ways. The choice of the method used depends on the nature of the sample:

(i) if the sample consists of crystalline fractions and an amorphous fraction of different chemical compositions, the amounts of each of the individual crystalline phases may be estimated using appropriate standard substances as described above; the amorphous fraction is then deduced indirectly by subtraction;
(ii) if the sample consists of one amorphous and one crystalline fraction, either as a 1-phase or a 2-phase mixture, with the same elemental composition, the amount of the crystalline phase (‘the degree of crystallinity’) can be estimated by measuring 3 areas of the diffractogram:

\[
\begin{align*}
A &= \text{total area of the peaks arising from diffraction from the crystalline fraction of the sample;} \\
B &= \text{total area below area } A; \\
C &= \text{background area (due to air scattering, fluorescence, equipment, etc.)}
\end{align*}
\]

When these areas have been measured, the degree of
crystallinity can be roughly estimated using the following formula:
\[
\% \text{crystallinity} = \frac{100A}{(A + B - C)}
\]

It is noteworthy that this method does not yield absolute degree-of-crystallinity values and hence is generally used for comparative purposes only. More sophisticated methods are also available, such as the Ruland method.

8. Single crystal structure

In general, the determination of crystal structures is performed from X-ray diffraction data obtained using single crystals. However, crystal structure analysis of organic crystals is a challenging task, since the lattice parameters are comparatively large, the symmetry is low and the scattering properties are normally very low. For any given crystalline form of a substance, knowledge of the crystal structure allows the calculation of the corresponding XRPD pattern, thereby providing a ‘preferred-orientation-free’ reference XRPD pattern, which may be used for phase identification.

There are many other applications of the X-ray powder diffraction technique that can be applied to crystalline pharmaceutical substances such as: determination of crystal structures, refinement of crystal structures, determination of crystallographic properties, characterization of crystallographic texture, etc. These applications are not described in this chapter.

An ‘ideal’ powder for diffraction experiments consists of a large number of small, randomly oriented spherical crystallites (coherently diffracting crystalline domains). If this number is sufficiently large, there are always enough crystallites in any diffusing orientation to give reproducible diffraction patterns.

Similarly, changes in the specimen can occur during data collection in the case of a non-equilibrium specimen (temperature, humidity).

If the crystal structures of all components are known, the Rietveld method can be used to quantify them with good accuracy. If the crystal structures of the components are not known, the Pawley or least squares methods can be used.

### 2.59 Test for Total Organic Carbon

Test for Total Organic Carbon is a method for measuring the amount of organic carbon, which forms organic compounds, in water. Normally, organic carbon can be oxidized to carbon dioxide by a dry decomposition method, where organic compounds are oxidized by combustion, or by a wet decomposition method, where organic compounds are oxidized by applying ultraviolet rays or by adding oxidizing agent. The amount of carbon dioxide generated in the decomposition process is measured using an appropriate method such as infrared gas analysis, electric conductivity measurement, or resistivity measurement. The amount of organic carbon in water can be calculated from the amount of carbon dioxide measured in one of the above methods.

There are two types of carbon in water: organic carbon and inorganic carbon. For measuring the amount of organic carbon, two approaches can be taken. One method is to measure the amount of total carbon in water, then to subtract the amount of inorganic carbon from that of total carbon. The other method is to remove inorganic carbon from the test water, then to measure the amount of remaining organic carbon.

1. Instrument

The instrument consists of a sample injection port, a decomposition device, a carbon dioxide separation block, a detector, and a data processor or a recorder. The instrument should be capable of measuring the amount of organic carbon down to 0.050 mg/L.

The sample injection port is designed to be able to accept a specific amount of sample injected by a microsyringe or other appropriate sampling devices. The decomposition device for the dry decomposition method consists of a combustion tube and an electric furnace to heat the sample. Both devices are adjusted to operate at specified temperatures. The decomposition device for the wet decomposition method consists of an oxidizing reaction box, an ultraviolet ray lamp, a decomposition aid injector, and a heater. The decomposition device for either method should be capable of generating not less than 0.450 mg/L of organic carbon when using a solution of sodium dodecylbenzenesulfonate (theoretical value of total organic carbon in this solution is 0.806 mg/L) as the sample. The carbon dioxide separation block removes water from carbon dioxide formed in the decomposition process or separates carbon dioxide from the decomposed gas. An infrared gas analyzer, electric conductivity meter or specific resistance meter is used as the detector which converts the concentration of carbon dioxide into electric signal. The data processor calculates the concentration of the total organic carbon in the sample based on the electric signal converted by the detector. The recorder records the electric signal intensity converted by the detector.

2. Reagents and standard solutions

(i) Water used for measuring organic carbon (water for measurement): This water is used for preparing standard solutions or decomposition aid or for rinsing the instrument. The amount of organic carbon in this water, when collected into a sample container, should be not more than 0.250 mg/L.

(ii) Standard potassium hydrogen phthalate solution: The concentration of this standard solution is determined as specified for the instrument. Dry potassium hydrogen phthalate (standard reagent) at 105°C for 4 hours, and allow it to cool in a desiccator (silica gel). Weigh accurately a prescribed amount of dried potassium hydrogen phthalate, and dissolve it in the water for measurement to prepare the standard solution.

(iii) Standard solution for measuring inorganic carbon: The concentration of this standard solution is determined as specified for the instrument. Dry sodium hydrogen carbonate in a desiccator (sulfuric acid) for not less than 18 hours. Dry sodium carbonate decahydrate separately between 500°C and 600°C for 30 minutes, and allow to cool in a desiccator (silica gel). Weigh accurately prescribed amounts of these compounds so that the ratio of their carbon content is 1:1, and dissolve them in the water for measurement to prepare the standard solution.

(iv) Decomposition aid: Dissolve a prescribed amount of potassium peroxodisulfate or other substances that can be used for the same purpose, in the water for measurement up to the concentration as specified for the instrument.

(v) Gas for removing inorganic carbon or carrier gas:
Nitrogen, oxygen, or other gases that can be used for the same purpose.
(vi) Acid for removing inorganic carbon: Dilute hydrochloric acid, phosphoric acid or other acids that can be used for the same purpose, with the water for measurement down to the concentration as specified for the instrument.

3. Apparatus
(i) Sample container and reagent container: Use a container made of the material which does not release organic carbon from its surface, such as hard glass. Soak the container before use in a mixture of diluted hydrogen peroxide solution (1 in 3) and dilute nitric acid (1:1), and wash well with the water for measurement.
(ii) Microsyringe: Wash a microsyringe with a mixture of a solution of sodium hydroxide (1 in 20) and ethanol (99.5) (1:1), or diluted hydrochloric acid (1 in 4), and rinse well with the water for measurement.

4. Procedure
Employ an analytical method suitable for the instrument used. Calibrate the instruments using the standard potassium hydrogen phthalate solution with the test procedure specified for the instrument.
It is recommended that this instrument be incorporated into the manufacturing line of the water to be tested.
Otherwise, this test should be performed in a clean circumstance where the use of organic solvents or other substances that may affect the result of this test is prohibited, using a large sample container to collect a large volume of the water to be tested. The measurement should be done immediately after the sample collection.

4.1. Measurement of organic carbon by subtracting inorganic carbon from total carbon
According to the test procedure specified for the instrument used, inject a suitable volume of the sample for measuring the expected amount of total carbon into the instrument from sample injection port, and decompose organic and inorganic carbon in the sample. Detect the generated carbon dioxide with the detector, and calculate the amount of total carbon in the sample using a data processor or a recorder. Change the setting of the instrument for measuring inorganic carbon exclusively, and measure the amount of inorganic carbon in the same manner as total carbon. The amount of organic carbon can be obtained by subtracting the amount of inorganic carbon from that of total carbon.

4.2. Measurement of organic carbon after removing inorganic carbon
Remove inorganic carbon by adding the acid for removing inorganic carbon to the sample, followed by bubbling the gas for removing inorganic carbon (e.g. nitrogen) into the sample. According to the test procedure specified for the instrument used, inject a suitable volume of the sample for measuring the expected amount of organic carbon into the instrument from sample injection port, and decompose organic carbon in the sample using a data processor or a recorder.

For the instrument where the removal of inorganic carbon is performed in the instrument, first inject a suitable volume of the sample for measuring the expected amount of organic carbon into the instrument from sample injection port, according to the test procedure specified for the instrument used. Then, remove inorganic carbon by adding the acid for removing inorganic carbon to the sample in the decomposition device, followed by bubbling the gas for removing inorganic carbon into the sample. Decompose organic carbon, detect the generated carbon dioxide with the detector, and calculate the amount of organic carbon using a data processor or a recorder.

2.60 Melting Point Determination
The melting point is defined to be the temperature at which a crystalline substance melts during heating, when the solid phase and the liquid phase are in an equilibrium. However, in this Pharmacopoeia it is conventionally defined to be the temperature at which the remaining solid sample melts completely when it is subjected to continuous heating and the change of the sample state that accompanies heating is accurately observed. Since a pure substance has an intrinsic melting point, it is used for the identification and/or confirmation of a substance and also as an indicator of the purity of a substance.
The melting point is determined by either of the following methods: Method 1 is applied to those substances of which the purity is comparably high and which can be pulverized, Method 2 to those substances which are insoluble in water and can not be readily pulverized, and Method 3 to petrolatum.
Unless otherwise specified, measurement is performed by Method 1.

1. Method 1
This method is applied to those substances of which the purity is comparably high and which can be pulverized.

1.1. Apparatus
Use the apparatus illustrated in the Fig. 2.60-1.
Alternatively, apparatus in which some of the procedures, such as stirring, heating, and cooling are automated, can be used.

(i) Bath fluid: Usually use clear silicone oil having a viscosity of 50 to 100 mm2/s at an ordinary temperature.
(ii) Thermometer with an immersion line: There are six types of thermometers, Type 1—Type 6, which are specified by an appropriate measuring temperature range. For melting points lower than 50°C, use a thermometer Type 1; for 40°C to 100°C, Type 2; for 90°C to 150°C, Type 3; for 140°C to 200°C, Type 4; for 190°C to 250°C, Type 5; for 240°C to 320°C, Type 6.
(iii) Capillary tube: Use a hard glass capillary tube 120 mm long, 0.8 to 1.2 mm in inner diameter and 0.2 to 0.3 mm thick, with one end closed.

1.2. Procedure
Pulverize the sample to a fine powder, and, unless otherwise specified, dry in a desiccator (silica gel) for 24 hours. When it is specified to do the test after drying, dry the sample under the conditions specified in the monograph before measurement. Place the sample in a dried capillary tube H, and pack it tightly so as to form a layer about 2.5 – 3.5 mm high by dropping the capillary repeatedly, with the closed end of H down, through a glass tube, about 70 cm long, held vertically on a glass or porous plate.
Heat the bath fluid B until the temperature rises to about 10°C below the expected melting point, place the thermometer D in the bath with the immersion line at the same level as
Fig. 2.60-1 Melting point determination apparatus

The figures are in mm.

the meniscus of the bath fluid, and insert capillary tube H into a coil spring G so that the packed sample is placed in a position corresponding to the center of the mercury bulb of the thermometer D. Continue heating to raise the temperature at a rate of approximately 3°C per minute until the temperature rises to 5°C below the expected melting point, then carefully regulate the rate of temperature increase to 1°C per minute.

Read the thermometer indication of the instantaneous temperature at which the sample liquefies completely and no solid is detectable in the capillary, and designate the indicated temperature as the melting point of the sample specimen.

1.2.1. System suitability test

Confirmation of the system suitability of the apparatus should be done periodically by using the Melting Point Standards. The Reference Standard is prepared for the suitability test of the apparatus when it is used with Type 2—Type 5 thermometers, and consists of 6 highly purified substances: acetonilide, acetophenetidin, caffeine, sulfanilamide, sulfapyridine, and vanillin. The label shows the certified melting points of the respective substances (the end point of the melting change), MPf.

After selecting one of the thermometers and the appropriate Melting Point Standard based upon the expected melting point of a sample specimen, perform a melting point measurement of the selected Reference Standard, according to the above procedure. When the value of the obtained melting point of the Reference Standard is within MPf ± 0.5°C in the case of vanillin and acetonilide, within MPf ± 0.8°C in the case of acetophenetidin and sulfanilamide, and within MPf ± 1.0°C in the case of sulfapyridine and caffeine, the apparatus is assumed to be suitable.

The above-mentioned measurement is repeated 3 times and the average is determined to be the melting point of the Reference Standard tested. When the above suitability test criteria are not met in a certain melting point measurement system of an apparatus and a Reference Standard, do the test again, after checking the packing of the sample specimen into the capillary tube, the locations and positioning of the thermometer and the capillary tube, the heating and stirring of the bath fluid, and the control of the temperature increasing rate. When a melting point measurement system does not meet the suitability test criteria again after checking these measuring conditions, the thermometer with an immersion line should be calibrated again or replaced with a new one.

2. Method 2

This method is applied to substances such as fats, fatty acids, paraffins or waxes.

2.1. Apparatus

Instead of the apparatus specified in Method 1, use a water-containing beaker as a bath fluid and a heating vessel. In this measurement, total immersion mercury-filled thermometers can also be used in place of the thermometer with an immersion line. Furthermore, the capillary tube should be the same as specified in Method 1, except that both ends of the tube are open.

2.2. Procedure

Carefully melt the sample at as low a temperature as possible, and, taking care to prevent bubbles, introduce it into a capillary tube to a height of about 10 mm. Allow the capillary containing the sample to stand for 24 hours at below 10°C, or for at least 1 hour in contact with ice, holding the capillary so that the sample can not flow out. Then attach the capillary to the thermometer by means of a rubber band so that the absorbed sample is located at a position corresponding to the center of the mercury bulb. Adjust the capillary tube in a water-containing beaker to such a position that the lower edge of the sample is located 30 mm below the water surface. Heat the beaker with constant stirring until the temperature rises to 5°C below the expected melting point. Then regulate the rate of temperature increase to 1°C per minute. The temperature at which the sample begins floating in the capillary is taken as the melting point of the sample specimen.

3. Method 3

This method is applied to petrolatums.

3.1. Apparatus

Instead of the apparatus specified in Method 1, use a water-containing beaker as a bath fluid and a heating vessel. When the value of the obtained melting point of the Reference Standard is within MPf ± 0.5°C in the case of vanillin and acetonilide, within MPf ± 0.8°C in the case of acetophenetidin and sulfanilamide, and within MPf ± 1.0°C in the case of sulfapyridine and caffeine, the apparatus is assumed to be suitable.

The above-mentioned measurement is repeated 3 times and the average is determined to be the melting point of the Reference Standard tested. When the above suitability test criteria are not met in a certain melting point measurement system of an apparatus and a Reference Standard, do the test again, after checking the packing of the sample specimen into the capillary tube, the locations and positioning of the thermometer and the capillary tube, the heating and stirring of the bath fluid, and the control of the temperature increasing rate. When a melting point measurement system does not meet the suitability test criteria again after checking these measuring conditions, the thermometer with an immersion line should be calibrated again or replaced with a new one.
3.2. Procedure
Melt the sample slowly by heating, with thorough stirring, until the temperature reaches 90–92°C. Discontinue the heating, and allow the sample to cool to 8 – 10°C above the expected melting point. Chill the bulb of the thermometer to held at a temperature about 16°C, while still cold, stick half of the thermometer bulb into the melted sample. Withdraw it immediately, hold vertically, cool until the attached sample becomes turbid, then dip the sample-bearing bulb for 5 minutes in water having a temperature below 16°C. Next, fix the thermometer securely in a test tube by means of a cork stopper so that the lower end is located 15 mm above the bottom. Suspend the test tube in a water-containing beaker held at a temperature about 16°C, and raise the temperature of the water bath to 30°C at a rate of 2°C per minute, then continue heating carefully at a rate of 1°C per minute until it reaches the melting point. Read the thermometer indication of the instantaneous temperature at which the first drop of the sample leaves the thermometer. If the variations between three repeated determinations are not more than 1°C, take the average of the three as the melting point. If any variation is greater than 1°C, make two additional measurements, and take the average of the five as the melting point.

3. Powder Property Determinations

3.01 Determination of Bulk and Tapped Densities

This test is harmonized with the European Pharmacopoeia and the U.S. Pharmacopeia. The parts of the test that are not harmonized are marked with symbols (•).

• Determination of Bulk and Tapped Densities is a method to determine the bulk densities of powdered drugs under loose and tapped packing conditions respectively. Loose packing is defined as the state obtained by pouring a powder sample into a vessel without any consolidation, and tapped packing is defined as the state obtained when the vessel containing the powder sample is to be repeatedly dropped a specified distance at a constant drop rate until the apparent volume of sample in the vessel becomes almost constant.

1. Bulk density
The bulk density of a powder is the ratio of the mass of an untapped powder sample and its volume including the contribution of the interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the spatial arrangement of particles in the powder bed. The bulk density is expressed in grams per milliliter (g/mL) although the international unit is kilogram per cubic meter (1 g/mL = 1000 kg/m³) because the measurements are made using cylinders. It may also be expressed in grams per cubic centimeter (g/cm³).

The bulking properties of a powder are dependent upon the preparation, treatment and storage of the sample, i.e. how it was handled. The particles can be packed to have a range of bulk densities and, moreover, the slightest disturbance of the powder bed may result in a changed bulk density. Thus, the bulk density of a powder is often very difficult to measure with good reproducibility and, in reporting the results, it is essential to specify how the determination was made.

The bulk density of a powder is determined by measuring the volume of a known mass of powder sample, that may have been passed through a sieve into a graduated cylinder (Method 1), or by measuring the mass of a known volume of powder that has been passed through a volumeter into a cup (Method 2) or a measuring vessel (Method 3). Method 1 and Method 3 are favoured.

1.1. Method 1: Measurement in a graduated cylinder
1.1.1. Procedure
Pass a quantity of powder sufficient to complete the test through a sieve with apertures greater than or equal to 1.0 mm, if necessary, to break up agglomerates that may have formed during storage; this must be done gently to avoid changing the nature of the material. Into a dry graduated cylinder of 250 mL (readable to 2 mL), gently introduce, without compacting, approximately 100 g of the test sample (m) weighed with 0.1 per cent accuracy. Carefully level the powder without compacting, if necessary, and read the unsettled apparent volume (V₀) to the nearest graduated unit. Calculate the bulk density in g per mL by the formula m/V₀.

Generally, replicate determinations are desirable for the determination of this property.

If the powder density is too low or too high, such that the test sample has an untapped apparent volume of either more than 250 mL or less than 150 mL, it is not possible to use 100 g of powder sample. Therefore, a different amount of powder has to be selected as test sample, such that its untapped apparent volume is 150 mL to 250 mL (apparent volume greater than or equal to 60 per cent of the total volume of the cylinder); the mass of the test sample is specified in the expression of results.

For test samples having an apparent volume between 50 mL and 100 mL, a 100 mL cylinder readable to 1 mL can be used; the volume of the cylinder is specified in the expression of results.

1.2. Method 2: Measurement in a volumeter
1.2.1. Apparatus
The apparatus (Fig. 3.01-1) consists of a top funnel fitted with a 1.0 mm sieve. The funnel is mounted over a baffle box containing four glass baffle plates over which the powder slides and bounces as it passes. At the bottom of the baf-

**Determination of Bulk and Tapped Densities**

**3.01 Determination of Bulk and Tapped Densities**

**1.3. Method 3: Measurement in a vessel**

**1.3.1. Apparatus**

The apparatus consists of a 100 mL cylindrical vessel of stainless steel with dimensions as specified in Fig. 3.01-2.

**1.3.2. Procedure**

Pass a quantity of powder sufficient to complete the test through a 1.0 mm sieve, if necessary, to break up agglomerates that may have formed during storage and allow the obtained sample to flow freely into the measuring vessel until it overflows. Carefully scrape the excess powder from the top of the vessel as described for Method 2. Determine the mass (m) of the powder to the nearest 0.1 per cent. Calculate the bulk density in g per mL by the formula $m/V_0$, in which $V_0$ is the volume of the cup and record the average of 3 determinations using 3 different powder samples.

**2. Tapped density**

The tapped density is an increased bulk density attained after mechanically tapping a container containing the powder sample.

The tapped density is obtained by mechanically tapping a graduated measuring cylinder or vessel containing the powder sample. After observing the initial powder volume or mass, the measuring cylinder or vessel is mechanically tapped, and volume or mass readings are taken until little further volume or mass change is observed. The mechanical tapping is achieved by raising the cylinder or vessel and allowing it to drop, under its own mass, a specified distance by either of 3 methods as described below. Devices that rotate the cylinder or vessel during tapping may be preferred to minimize any possible separation of the mass during tapping down.

**2.1. Method 1**

**2.1.1. Apparatus**

The apparatus (Fig. 3.01-3) consists of the following:

(i) a 250 mL graduated cylinder (readable to 2 mL) with a mass of 220 ± 44 g.

(ii) a settling apparatus capable of producing, in 1 min, either nominally 250 ± 15 taps from a height of 3 ± 0.2 mm, or nominally 300 ± 15 taps from a height of 14 ± 2 mm. The support for the graduated cylinder, with its holder, has a mass of 450 ± 10 g.

**2.1.2. Procedure**

Proceed as described above for the determination of the bulk volume ($V_f$).

Secure the cylinder in the holder. Carry out 10, 500 and 1250 taps on the same powder sample and read the corresponding volumes $V_{10}$, $V_{500}$ and $V_{1250}$ to the nearest graduated unit. If the difference between $V_{500}$ and $V_{1250}$ is less than or equal to 2 mL, $V_{1250}$ is the tapped volume. If the difference between $V_{500}$ and $V_{1250}$ exceeds 2 mL, repeat increments such as 1250 taps, until the difference between succeeding measurements is less than or equal to 2 mL. Fewer taps may be appropriate for some powders, when validated. Calculate the tapped density (g/mL) using the formula $m/V_f$, in which $V_f$ is the final tapped volume. Generally, replicate determinations are desirable for the determination of this property. Specify the drop height with the results.

If it is not possible to use a 100 g test sample, use a reduced amount and a suitable 100 mL graduated cylinder (readable to 1 mL) weighing 130 ± 16 g and mounted on a holder weighing 240 ± 12 g. The modified test conditions are specified in the expression of the results.

**2.2. Method 2**

**2.2.1. Procedure**

Proceed as directed under Method 1 except that the mechanical tester provides a fixed drop of 3 ± 0.2 mm at a nominal rate of 250 taps per minute.

---

**Fig. 3.01-3**
3.02 Specific Surface Area by Gas Adsorption

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopoeia. The parts of the text that are not harmonized are marked with symbols (• •).

The specific surface area determination method is a method to determine specific surface area (the total surface area of powder per unit mass) of a pharmaceutical powder sample by using gas adsorption method. The specific surface area of a powder is determined by physical adsorption of a gas on the surface of the solid and by calculating the amount of adsorbate gas corresponding to a monomolecular layer on the surface. Physical adsorption results from relatively weak forces (van der Waals forces) between the adsorbate gas molecules and the adsorbent surface of the test powder. The determination is usually carried out at the temperature of liquid nitrogen. The amount of gas adsorbed can be measured by a volumetric or continuous flow procedure.

1. Measurements

1.1. Multi-point measurement

When the gas is physically adsorbed by the powder sample, the following relationship (Brunauer, Emmett and Teller (BET) adsorption isotherm) holds when the relative pressure ($P/P_0$) is in the range of 0.05 to 0.30 for pressure $P$ of the adsorbate gas in equilibrium for the volume of gas adsorbed, $V_0$.

$$\frac{1}{V_0} = \frac{1}{V_m} + \frac{C}{V_m P} + \frac{(1/C)}{\left(\frac{V_m}{P}\right)}$$

$P$: Partial vapour pressure of adsorbate gas in equilibrium with the surface at $-195.8^\circ C$ (b. p. of liquid nitrogen), in pascals

$P_0$: Saturated pressure of adsorbate gas, in pascals

$V_0$: Volume of gas adsorbed at standard temperature and pressure (STP) [0°C and atmospheric pressure (1.013 × 10^5 Pa)], in milliliters

$V_m$: Volume of gas adsorbed at STP to produce an apparent monolayer on the sample surface, in milliliters

$C$: Dimensionless constant that is related to the enthalpy of adsorption of adsorbate gas on the powder sample

A value of $V_0$ is measured at each of not less than 3 values of $P/P_0$. Then the BET value, $1/[V_m((P_0/P) - 1)]$, is plotted against $P/P_0$ according to equation (1). This plot should yield a straight line usually in the approximate relative pressure range 0.05 to 0.3. The data are considered acceptable if the correlation coefficient, $r$, of the linear regression is not less than 0.9975; that is, $r^2$ is not less than 0.995. From the resulting linear plot, the slope, which is equal to $(C - 1)/V_m$, and the intercept, which is equal to $1/(V_m C)$, are evaluated by linear regression analysis. From these values, $V_m$ is calculated as $1/(slope + intercept)$, while $C$ is calculated as $(slope/intercept) + 1$. From the value of $V_m$ so determined, the specific surface area, $S$, in m²g⁻¹, is calculated by the equation:

$$S = \frac{(V_m N a)}{(m \times 22400)}$$

$N$: Avogadro constant ($6.022 \times 10^{23}$ mol⁻¹),

$a$: Effective cross-sectional area of one adsorbate molecule, in square meters ($0.162 \times 10^{-18}$ m² for nitrogen and $0.195 \times 10^{-18}$ m² for krypton)

$m$: Mass of test powder, in grams

22,400: Volume, in milliliters, occupied by one mole of the adsorbate gas at STP allowing for minor departures from the ideal

A minimum of 3 data points is required. Additional meas-
urements may be carried out, especially when non-linearity is obtained at a $P/P_0$ value close to 0.3. Because non-linearity is often obtained at a $P/P_0$ value below 0.05, values in this region are not recommended. The test for linearity, the treatment of the data, and the calculation of the specific surface area of the sample are described above.

1.2. Single-point measurement

Normally, at least 3 measurements of $V_s$ each at different values of $P/P_0$ are required for the determination of specific surface area by the dynamic flow gas adsorption technique (Method I) or by volumetric gas adsorption (Method II). However, under certain circumstances described below, it may be acceptable to determine the specific surface area of a powder from a single value of $V_s$ measured at a single value of $P/P_0$, such as 0.300 (corresponding to 0.300 mole of nitrogen or 0.001038 mole fraction of krypton), using the following equation for calculating $V_m$:

$$V_m = V_i[1 - (P/P_0)] \quad (3)$$

The single-point method may be employed directly for a series of very similar powder samples of a given material for which the material constant $C$ is much greater than unity. These circumstances may be verified by comparing values of specific surface area determined by the single-point method with that determined by the multiple-point method for the series of powder samples. Close similarity between the single-point values and multiple-point values suggests that $1/C$ approaches zero. The single-point method may be employed indirectly for a series of very similar powder samples of a given material for which the material constant $C$ is not infinite but may be assumed to be invariant. Under these circumstances, the error associated with the single-point method can be reduced or eliminated by using the multiple-point method to evaluate $C$ for one of the samples from the series from the BET plot, from which $C$ is calculated as $(1 + \text{slope/intercept})$.

Then $V_m$ is calculated from the single value of $V_s$ measured at a single value of $P/P_0$ by the equation:

$$V_m = V_i[(P_0 - P)/P_0] \cdot [(1/C) + [(C - 1)/C \times (P/P_0)] \quad (4)$$

2. Sample preparation

Before the specific surface area of the sample can be determined, it is necessary to remove gases and vapors that may have become physically adsorbed onto the surface during storage and handling. If outgassing is not achieved, the specific surface area may be reduced or may be variable because some parts of surface area are covered with molecules of the previously adsorbed gases or vapors. The outgassing conditions are critical for obtaining the required precision and accuracy of specific surface area measurements on pharmaceuticals because of the sensitivity of the surface of the materials. The outgassing conditions must be demonstrated to yield reproducible BET plots, a constant weight of test powder, and no detectable physical or chemical changes in the test powder.

The outgassing conditions defined by the temperature, pressure and time should be so chosen that the original surface of the solid is reproduced as closely as possible.

Outgassing of many substances is often achieved by applying a vacuum, by purging the sample in a flowing stream of a non-reactive, dry gas, or by applying a desorption-adsorption cycling method. In either case, elevated temperatures are sometimes applied to increase the rate at which the contaminants leave the surface. Caution should be exercised when outgassing powder samples using elevated temperatures to avoid affecting the nature of the surface and the integrity of the sample.

If heating is employed, the recommended temperature and time of outgassing are as low as possible to achieve reproducible measurement of specific surface area in an acceptable time. For outgassing sensitive samples, other outgassing methods such as the desorption-adsorption cycling method may be employed.

The standard technique is the adsorption of nitrogen at liquid nitrogen temperature.

For powders of low specific surface area ($<0.2 \, \text{m}^2\text{g}^{-1}$) the proportion adsorbed is low. In such cases the use of krypton at liquid nitrogen temperature is preferred because the low vapor pressure exerted by this gas greatly reduces error. All gases used must be free from moisture.

Accurately weigh a quantity of the test powder such that the total surface of the sample is at least $1 \, \text{m}^2$ when the adsorbate is nitrogen and $0.5 \, \text{m}^2$ when the adsorbate is krypton. Lower quantities of sample may be used after appropriate validation. Because the amount of gas adsorbed under a given pressure tends to increase on decreasing the temperature, adsorption measurements are usually made at a low temperature. Measurement is performed at $-195.8^\circ \text{C}$, the boiling point of liquid nitrogen.

Adsorption of gas should be measured either by Method I or Method II.

3. Methods

3.1. Method I: The dynamic flow method

In the dynamic flow method (see Fig. 3.02-1), the recommended adsorbate gas is dry nitrogen or krypton, while helium is employed as a diluent gas, which is not adsorbed under the recommended conditions. A minimum of 3 mixtures of...
3.03 Powder Particle Density Determination

The appropriate adsorbate gas with helium are required within the $P/P_0$ range 0.05 to 0.30.

The gas detector-integrator should provide a signal that is approximately proportional to the volume of the gas passing through it under defined conditions of temperature and pressure. For this purpose, a thermal conductivity detector with an electronic integrator is one among various suitable types. A minimum of 3 data points within the recommended range of 0.05 to 0.30 for $P/P_0$ is to be determined.

A known mixture of the gases, usually nitrogen and helium, is passed through a thermal conductivity cell, through the sample again through the thermal conductivity cell and then to a recording potentiometer. Immerse the sample cell in liquid nitrogen, then the sample adsorbs nitrogen from the mobile phase. This unbalances the thermal conductivity cell, and a pulse is generated on a recorder chart.

Remove from the coolant; this gives a desorption peak equal in area and in the opposite direction to the adsorption peak.

Since this is better defined than the adsorption peak, it is the one used for the determination.

To effect the calibration, inject a known quantity of adsorbate into the system, sufficient to give a peak of similar magnitude to the desorption peak and obtain the proportion of gas volume per unit peak area.

Use a nitrogen/helium mixture for a single-point determination and several such mixtures or premixing 2 streams of gas for a multiple-point determination. Calculation is essentially the same as for the volumetric method.

3.2. Method 2: The volumetric method

In the volumetric method (see Fig. 3.02-2), the recommended adsorbate gas is nitrogen is admitted into the evacuated space above the previously outgassed powder sample to give a defined equilibrium pressure, $P$, of the gas. The use of a diluent gas, such as helium, is therefore unnecessary, although helium may be employed for other purposes, such as to measure the dead volume.

Since only pure adsorbate gas, instead of a gas mixture, is employed, interfering effects of thermal diffusion are avoided in this method.

Admit a small amount of dry nitrogen into the sample tube to prevent contamination of the clean surface, remove the sample tube, insert the stopper, and weigh it. Calculate the weight of the sample. Attach the sample tube to the volumetric apparatus. Cautiously evacuate the sample down to the specified pressure (e.g. between 2 Pa and 10 Pa). Alternatively, some instruments operate by evacuating to a defined rate of pressure change (e.g. less than 13 Pa/30 s) and holding for a defined period of time before commencing the next step.

If the principle of operation of the instrument requires the determination of the dead volume in the sample tube, for example, by the admission of a non-adsorbed gas, such as helium, this procedure is carried out at this point, followed by evacuation of the sample. The determination of dead volume may be avoided using difference measurements, that is, by means of reference and sample tubes connected by a differential transducer.

Raise a Dewar vessel containing liquid nitrogen at $-195.8^\circ$C up to a defined point on the sample cell. Admit a sufficient volume of adsorbate gas to give the lowest desired relative pressure. Measure the volume adsorbed, $V_a$. For multipoint measurements, repeat the measurement of $V_a$ at successively higher $P/P_0$ values. When nitrogen is used as the adsorbate gas, $P/P_0$ values of 0.10, 0.20, and 0.30 are often suitable.

4. Reference materials

Periodically verify the functioning of the apparatus using appropriate reference materials of known surface area, such as $\alpha$-alumina for specific surface area determination, which should have a specific surface area similar to that of the sample to be examined.

3.03 Powder Particle Density Determination

This test is harmonized with the European Pharmacopoeia and the U.S. Pharmacopoeia. The parts of the test that are not harmonized are marked with symbols (•). Powder Particle Density Determination is •a method to determine particle density of powdered pharmaceutical drugs or raw materials of drugs, and generally performed using a gas displacement pycnometer. The gas pycnometric density is determined by measuring the volume occupied by a known mass of powder which is equivalent to the volume of gas displaced by the powder using a gas displacement pycnometer. In gas pycnometric density measurements, the volume determined excludes the volume occupied by open pores; however, it includes the volume occupied by sealed pores or pores inaccessible to the gas.

Usually, helium is used as a test gas due to its high diffusivity into small open pores. If gases other than helium are used, different values would be obtained, since the penetration of the gas is dependent on the size of the pore as well as the cross-sectional area of the gas.

The measured density is a volume weighted average of the densities of individual powder particles. It is called the particle density, distinct from the true density of solid or the bulk density of powder. The density of solids are expressed in
1. **Apparatus**

The schematic diagram of particle density apparatus for gas displacement pycnometric measurement is shown in Fig. 3.03-1. The apparatus consists of a test cell in which the sample is placed, an expansion cell and a manometer (M). The test cell, with an empty cell volume \(V_c\), is connected through a valve (A) to an expansion cell, with a volume \(V_r\). Generally, helium is used as the measurement gas. The apparatus has to be equipped with a system capable of pressuring the test cell to the defined pressure \(P\) through the manometer.

2. **Calibration of apparatus**

The volumes of the test cell \(V_c\) and the expansion cell \(V_r\) must be accurately determined to the nearest 0.001 cm³, and to assure accuracy of the results of volume obtained, calibration of the apparatus is carried out as follows using a calibration ball of known volume for particle density measurement. The final pressures \(P_f\) are determined for the initial empty test cell followed by the test cell placed with the calibration ball for particle density measurement in accordance with the procedures, and \(V_c\) and \(V_r\) are calculated using the equation described in the section of Procedure. Calculation can be made taking into account that the sample volume \(V_s\) is zero in the first run.

3. **Procedure**

The gas pycnometric density measurement is performed at a temperature between 15°C and 30°C and must not vary by more than 2°C during the course of measurement. Volatile contaminants in the powder are removed by degassing the powder under a constant purge of helium prior to the measurement. Occasionally, powders may have to be degassed under vacuum. Because volatiles may be evolved during the measurement, weighing of the sample is done after the pycnometric measurement of volume.

Weigh the mass of the test cell and record it. After weighing out the amount of the sample as described in the individual monograph and placing it in the test cell, seal the cell in the pycnometer.

Open the valve (A) which connects the expansion cell with the test cell, confirm with the manometer (M) that the pressure inside the system is stable, and then read the system reference pressure \(P_i\). Secondly, close the valve that connects to the two cells, and introduce the measurement gas into the test cell to achieve positive pressure. Confirm with the manometer that the pressure inside the system is stable, and then read the initial pressure \(P_i\). Open the valve to connect the test cell with the expansion cell. After confirming that the indicator of the manometer is stable, read the final pressure \(P_f\), and calculate the sample volume \(V_s\) with the following equation:

\[
V_s = V_c - \frac{V_r}{P_f - P_i - 1}
\]

\(V_c\): Expansion volume (cm³)
\(V_r\): Cell volume (cm³)
\(V_s\): Sample volume (cm³)
\(P_i\): Initial pressure (kPa)
\(P_f\): Final pressure (kPa)
\(P_s\): System reference pressure (kPa)

Repeat the measurement sequence for the same powder sample until consecutive measurements of the sample volume agree to within 0.2%, and calculate the mean of sample volumes \(V_s\). Finally, unload the test cell, weigh the mass of the test cell, and calculate the final sample mass \(m\) by deducting the empty cell mass from the test cell mass. The powder particle density \(\rho\) is calculated by the following equation:

\[
\rho = \frac{m}{V_s}
\]

\(\rho\): Powder particle density in g/cm³,
\(m\): Final sample mass in g,
\(V_s\): Sample volume in cm³

If the pycnometer differs in operation or construction from the one shown in Fig. 3.03-1, follow the instructions of the manufacturer of the pycnometer. The sample conditioning is indicated with the results. For example, indicate whether the sample was tested as is or dried under specific conditions such as those described for loss on drying.

### 3.04 Particle Size Determination

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia. The parts of the text that are not harmonized are marked with symbols (** •**).

**Particle Size Determination is a method to determine directly or indirectly morphological appearance, shape, size and its distribution of powdered pharmaceutical drugs and excipients to examine their micromeritic properties. Optical microscopy and analytical sieving method may be used depending on the measuring purpose and the properties of test specimen.**

#### 1. **Method 1. Optical Microscopy**

*The optical microscopy is used to observe the morphological appearance and shape of individual particle either directly with the naked eye or by using a microscopic photograph, in order to measure the particle size. The particle size distribution can also be determined by this method. It is also possible with this method to measure the size of the individ-
ual particle even when different kinds of particles mingle if they are optically distinguishable. Data processing techniques, such as image analysis, can be useful for determining the particle size distribution.

This method for particle characterization can generally be applied to particles 1 μm and greater. The lower limit is imposed by the resolving power of the microscope. The upper limit is less definite and is determined by the increased difficulty associated with the characterization of larger particles. Various alternative techniques are available for particle characterization outside the applicable range of optical microscopy. Optical microscopy is particularly useful for characterizing particles that are not spherical. This method may also serve as a base for the calibration of faster and more routine methods that may be developed.

1.1. Apparatus

Use a microscope that is stable and protected from vibration. The microscope magnification (product of the objective magnification, ocular magnification, and additional magnifying components) must be sufficient to allow adequate characterization of the smallest particles to be classified in the test specimen. The greatest numerical aperture of the objective should be sought for each magnification range. Polarizing filters may be used in conjunction with suitable analyzers and retardation plates. Color filters of relatively narrow spectral transmission should be used with achromatic objectives and are preferable with apochromats and are required for appropriate color rendition in photomicrography. Condensers corrected for at least spherical aberration should be used in the microscope substage and with the lamp. The numerical aperture of the substage condenser should match that of the objective under the condition of use; this is affected by the actual aperture of the condenser diaphragm and the presence of immersion oils.

1.1.1. Adjustment

The precise alignment of all elements of the optical system and proper focusing are essential. The focusing of the elements should be done in accordance with the recommendations of the microscope manufacturer. Critical axial alignment is recommended.

1.1.1.1. Illumination

A requirement for good illumination is a uniform and adjustable intensity of light over the entire field of view; Kohler illumination is preferred. With colored particles, choose the color of the filters used so as to control the contrast and detail of the image.

1.1.1.2. Visual Characterization

The magnification and numerical aperture should be sufficiently high to allow adequate resolution of the images of the particles to be characterized. Determine the actual magnification using a calibrated stage micrometer to calibrate an ocular micrometer. Errors can be minimized if the magnification is sufficient that the image of the particle is at least 10 ocular divisions. Each objective must be calibrated separately. To calibrate the ocular scale, the stage micrometer scale and the ocular scale should be aligned. In this way, a precise determination of the distance between ocular stage divisions can be made.

When the particle size is measured, an ocular micrometer is inserted at the position of the ocular diaphragm, and a calibrated stage micrometer is placed at the center of the microscope stage and fixed in place. The ocular is attached to the lens barrel and adjusted to the focus point of the stage micrometer scale. Then, the distance between the scales of the two micrometers is determined, and the sample size equivalent 1 division of the ocular scale is calculated using the following formula:

\[ \text{Particle size equivalent} = \frac{\text{Length on the stage micrometer (μm)}}{\text{Number of scale divisions on the ocular micrometer}} \]

The stage micrometer is removed and the test specimen is placed on the microscope stage. After adjusting the focus, the particle sizes are determined from the number of scale divisions read through the ocular.

Several different magnifications may be necessary to characterize materials having a wide particle size distribution.

1.1.1.3. Photographic Characterization

If particle size is to be determined by photographic methods, take care to ensure that the object is sharply focused at the plane of the photographic emulsion. Determine the actual magnification by photographing a calibrated stage micrometer, using photographic film of sufficient speed, resolving power, and contrast. Exposure and processing should be identical for photographs of both the test specimen and the determination of magnification. The apparent size of a photographic image is influenced by the exposure, development, and printing processes as well as by the resolving power of the microscope.

1.2. Preparation of the Mount

The mounting medium will vary according to the physical properties of the test specimen. Sufficient, but not excessive, contrast between the specimen and the mounting medium is required to ensure adequate detail of the specimen edge. The particles should rest in one plane and be adequately dispersed to distinguish individual particles of interest. Furthermore, the particles must be representative of the distribution of sizes in the material and must not be altered during preparation of the mount. Care should be taken to ensure that this important requirement is met. Selection of the mounting medium must include a consideration of the analyte solubility.

1.3. Characterization

1.3.1. Crystallinity Characterization

The crystallinity of a material may be characterized to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance. Unless otherwise specified in the individual monograph, mount a few particles of the specimen in mineral oil on a clean glass slide. Examine the mixture using a polarizing microscope: the particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

1.3.2. Limit Test of Particle Size by Microscopy

Weigh a suitable quantity of the powder to be examined (for example, 10 to 100 mg), and suspend it in 10 mL of a suitable medium in which the powder does not dissolve, adding, if necessary, a wetting agent. A homogeneous suspension of particles can be maintained by suspending the particles in a medium of similar or matching density and by providing adequate agitation. Introduce a portion of the homogeneous suspension into a suitable counting cell, and scan under a microscope an area corresponding to not less than 10 μg of the powder to be examined. Count all the particles having a maximum dimension greater than the prescribed size limit. The size limit and the permitted number of particles exceeding the limit are defined for each substance.
1.3.3. Particle Size Characterization

The measurement of particle size varies in complexity depending on the shape of the particle and the number of particles characterized must be sufficient to ensure an acceptable level of uncertainty in the measured parameters\(^1\). For spherical particles, size is defined by the diameter. For irregular particles, a variety of definitions of particle size exist. In general, for irregularly shaped particles, characterization of particle size must also include information on the type of diameter measured as well as information on particle shape. Several commonly used measurements of particle size are defined below (see Fig. 3.04-1).

(i) Feret’s Diameter: The distance between imaginary parallel lines tangent to a randomly oriented particle and perpendicular to the ocular scale.

(ii) Martin’s Diameter: The diameter of the particle at the point that divides a randomly oriented particle into two equal projected areas.

(iii) Projected area Diameter: The diameter of a circle that has the same projected area as the particle.

(iv) Length: The longest dimension from edge to edge of a particle oriented parallel to the ocular scale.

(v) Width: The longest dimension of the particle measured at right angles to the length.

1.3.4. Particle Shape Characterization

For irregularly shaped particles, characterization of particle size must also include information on particle shape. The homogeneity of the powder should be checked using appropriate magnification. The following defines some commonly used descriptors of particle shape (see Fig. 3.04-2).

(i) Acicular: Slender, needle-like particle of similar width and thickness.

(ii) Columnar: Long, thin particle with a width and thickness that are greater than those of an acicular particle.

(iii) Flake: Thin, flat particle of similar length and width.

(iv) Plate: Flat particles of similar length and width but with greater thickness than flakes.

(vi) Equant: Particles of similar length, width, and thickness; both cubical and spherical particles are included.

1.3.5. General Observations

A particle is generally considered to be the smallest discrete unit. A particle may be a liquid or semisolid droplet; a single crystal or polycrystalline; amorphous or an agglomerate. Particles may be associated. This degree of association may be described by the following terms.

(i) Lamellar: Stacked plates.

(ii) Aggregate: Mass of adhered particles.

(iii) Agglomerate: Fused or cemented particles.

(iv) Conglomerate: Mixture of two or more types of particles.

(v) Spherulite: Radial cluster.

(vi) Drusy: Particle covered with tiny particles.

Particle condition may be described by the following terms.

(i) Edges: Angular, rounded, smooth, sharp, fractured.

(ii) Optical: Color (using proper color balancing filters), transparent, translucent, opaque.

(iii) Defects: Occlusions, inclusions.

Surface characteristics may be described by the following terms.

(i) Cracked: Partial split, break, or fissure.

(ii) Smooth: Free of irregularities, roughness, or projections.

(iii) Porous: Having openings or passageways.

(iv) Rough: Bumpy, uneven, not smooth.

(v) Pitted: Small indentations.

The analytical sieving method is a method to estimate the particle size distribution of powdered pharmaceutical drugs by sieving. The particle size determined by this method is shown as the size of a minimum sieve opening through which the particle passes. "Powder" here means a gathering of numerous solid particles.

Sieving is one of the oldest methods of classifying powders and granules by particle size distribution. When using a woven sieve cloth, the sieving will essentially sort the particles by their intermediate size dimension (i.e., breadth or width). Mechanical sieving is most suitable where the majority of the particles are larger than about 75 \(\mu m\). For smaller particles, the light weight provides insufficient force during sieving to overcome the surface forces of cohesion and adhesion that cause the particles to stick to each other and to the sieve, and thus cause particles that would be expected to pass through the sieve to be retained. For such materials other means of agitation such as air-jet sieving or sonic sifting may be more appropriate. Nevertheless, sieving can sometimes be used for some powders or granules having median particle sizes smaller than 75 \(\mu m\) where the method can be validated. In pharmaceutical terms, sieving is usually the method of choice for classification of the coarser grades.
of single powders or granules. It is a particularly attractive method in that powders and granules are classified only on the basis of particle size, and in most cases the analysis can be carried out in the dry state.

Among the limitations of sieving method are the need for an appreciable amount of sample (normally at least 25 g, depending on the density of the powder or granule, and the diameter of test sieves) and difficulty in sieving oily or other cohesive powders or granules that tend to clog the sieve openings. The method is essentially a two-dimensional estimate of size because passage through the sieve aperture is frequently more dependent on maximum width and thickness than on length.

This method is intended for estimation of the total particle size distribution of a single material. It is not intended for determination of the proportion of particles passing or retained on one or two sieves.

Estimate the particle size distribution as described under Dry Sieving Method, unless otherwise specified in the individual monograph. Where difficulty is experienced in reaching the endpoint (i.e., material does not readily pass through the sieves) or when it is necessary to use the finer end of the sieving range (below 75 μm), serious consideration should be given to the use of an alternative particle-sizing method.

Sieving should be carried out under conditions that do not cause the test sample to gain or lose moisture. The relative humidity of the environment in which the sieving is carried out should be controlled to prevent moisture uptake or loss by the sample. In the absence of evidence to the contrary, analytical test sieving is normally carried at ambient humidity. Any special conditions that apply to a particular material should be detailed in the individual monograph.

Principles of Analytical Sieving: Analytical test sieves are constructed from a woven-wire mesh, which is of simple weave that is assumed to give nearly square apertures and is sealed into the base of an open cylindrical container. The basic analytical method involves stacking the sieves on top of one another in ascending degrees of coarseness, and then placing the test powder on the top sieve.

The nest of sieves is subjected to a standardized period of agitation, and then the weight of material retained on each sieve is accurately determined. The test gives the weight percentage of powder in each sieve size range.

This sieving process for estimating the particle size distribution of a single pharmaceutical powder is generally intended for use where at least 80% of the particles are larger than 75 μm. The size parameter involved in determining particle size distribution by analytical sieving is the length of the size of the minimum square aperture through which the particle will pass.

2.1. Procedure

2.1.1. Test Sieves

Test sieves suitable for pharmacopoeial tests conform to the most current edition of International Organisation for Standardization (ISO) Specification ISO 3310-1: Test sieves—Technical requirements and testing (see Table 3.04-1).

Unless otherwise specified in the monograph, use those ISO sieves listed in the Table 3.04-1 as recommended in the particular region.

Sieves are selected to cover the entire range of particle sizes present in the test specimen. A nest of sieves having a \( \sqrt{2} \) progression of the area of the sieve openings is recommended. The nest of sieves is assembled with the coarsest screen at the top and the finest at the bottom. Use micrometers or millimeters in denoting test sieve openings. [Note—Mesh numbers are provided in the table for conversion purposes only.] Test sieves are made from stainless steel or, less preferably, from brass or other suitable non-reactive wire.

2.1.1.1. Calibration of test sieves

Calibration and recalibration of test sieves is in accordance with the most current edition of ISO 3310-1. Sieves should be carefully examined for gross distortions and fractures, especially at their screen frame joints, before use. Sieves may be calibrated optically to estimate the average opening size, and opening variability, of the sieve mesh. Alternatively, for the evaluation of the effective opening of test sieves in the size range of 212 to 850 μm, Standard Glass Spheres are available. Unless otherwise specified in the individual monograph, perform the sieve analysis at controlled room temperature and at ambient relative humidity.

2.1.1.2. Cleaning Test Sieves

Ideally, test sieves should be cleaned using only an air jet or a liquid stream. If some apertures remain blocked by test particles, careful gentle brushing may be used as a last resort.

2.1.2. Test Specimen

If the test specimen weight is not given in the monograph for a particular material, use a test specimen having a weight between 25 and 100 g, depending on the bulk density of the material, and test sieves having a 200 mm diameter. For 76 mm sieves the amount of material that can be accommodated is approximately 1/7th that which can be accommodated on a 200 mm sieve. Determine the most appropriate weight for a given material by test sieving accurately weighed specimens of different weights, such as 25, 50, and 100 g, for the same time period on a mechanical shaker. [Note—If the test results are similar for the 25-g and 50-g specimens, but the 100-g specimen shows a lower percentage through the finest sieve, the 100-g specimen size is too large.] Where only a specimen of 10 to 25 g is available, smaller diameter test sieves conforming to the same mesh specifications may be substituted, but the endpoint must be re-determined. The use of test samples having a smaller mass (e.g. down to 5 g) may be needed. For materials with low apparent particle density, or for materials mainly comprising particles with a highly iso-diametrical shape, specimen weights below 5 g for a 200 mm screen may be necessary to avoid excessive blocking of the sieve. During validation of a particular sieve analysis method, it is expected that the problem of sieve blocking will have been addressed.

If the test material is prone to picking up or losing significant amounts of water with varying humidity, the test must be carried out in an appropriately controlled environment. Similarly, if the test material is known to develop an electrostatic charge, careful observation must be made to ensure that such charging is not influencing the analysis. An antistatic agent, such as colloidal silicon dioxide and/or aluminum oxide, may be added at a 0.5 percent (m/m) level to minimize this effect. If both of the above effects cannot be eliminated, an alternative particle-sizing technique must be selected.

2.1.3. Agitation Methods

Several different sieve and powder agitation devices are

commercially available, all of which may be used to perform sieve analyses. However, the different methods of agitation may give different results for sieve analyses and endpoint determinations because of the different types and magnitude of the forces acting on the individual particles under test. Methods using mechanical agitation or electromagnetic agitation, and that can induce either a vertical oscillation or a horizontal circular motion, or tapping or a combination of both tapping and horizontal circular motion are available. Entrainment of the particles in an air stream may also be used. The results must indicate which agitation method was used and the agitation parameters used (if they can be varied), since changes in the agitation conditions will give different results for the sieve analysis and endpoint determinations, and may be sufficiently different to give a failing result under some circumstances.

2.1.4. Endpoint Determination

The test sieving analysis is complete when the weight on any of the test sieves does not change by more than 5% or 0.1 g (10% in the case of 76 mm sieves) of the previous weight on that sieve. If less than 5% of the total specimen weight is present on a given sieve, the endpoint for that sieve is increased to a weight change of not more than 20% of the previous weight on that sieve.

If more than 50% of the total specimen weight is found on any one sieve, unless this is indicated in the monograph, the test should be repeated, but with the addition to the sieve nest of a more coarse sieve intermediate between that carrying the excessive weight and the next coarsest sieve in the original nest, i.e., addition of the ISO series sieve omitted from the nest of sieves.

2.2. Sieving Methods

2.2.1. Mechanical Agitation (Dry Sieving Method)

Tare each test sieve to the nearest 0.1 g. Place an accurately weighed quantity of test specimen on the top (coarsest) sieve, and place the lid. Agitate the nest of sieves for 5 minutes. Then carefully remove each from the nest without loss of material. Reweigh each sieve, and determine the weight of material on each sieve. Determine the weight of material in the collecting pan in a similar manner. Reassemble the nest of sieves, and agitate for 5 minutes. Remove and weigh each sieve as previously described. Repeat these steps until the endpoint criteria are met (see Endpoint Determination under Test Sieves). Upon completion of the analysis, reconcile the weights of material. Total losses must not exceed 5% of the weight of the original test specimen.

Repeat the analysis with a fresh specimen, but using a single sieving time equal to that of the combined times used above. Confirm that this sieving time conforms to the requirements for endpoint determination. When this endpoint has been validated for a specific material, then a single fixed time of sieving may be used for future analyses, providing the particle size distribution falls within normal variation.

If there is evidence that the particles retained on any sieve are aggregates rather than single particles, the use of mechanical dry sieving is unlikely to give good reproducibility; a different particle size analysis method should be used.

2.2.2. Air Entrainment Methods (Air Jet and Sonic Shifter Shaking)

Different types of commercial equipment that use a moving air current are available for sieving. A system that uses a single sieve at a time is referred to as air jet sieving. It uses the same general sieving methodology as that described under the Dry Sieving Method, but with a standardized air jet replacing the normal agitation mechanism. It requires sequential analyses on individual sieves starting with the finest sieve to obtain a particle size distribution. Air jet sieving often includes the use of finer test sieves than used in ordinary dry sieving. This technique is more suitable where only oversize or undersize fractions are needed.

In the sonic sifting method, a nest of sieves is used, and the test specimen is carried in a vertically oscillating column of air that lifts the specimen and then carries it back against the mesh openings at a given number of pulses per minute. It may be necessary to lower the sample amount to 5 g, when sonic shifting is employed.

The air jet sieving and sonic sieving methods may be useful for powders or granules when mechanical sieving techniques are incapable of giving a meaningful analysis.

These methods are highly dependent upon proper dispersion of the powder in the air current. This requirement may be hard to achieve if the method is used at the lower end of the sieving range (i.e., below 75 μm), when the particles tend to be more cohesive, and especially if there is any tendency for the material to develop an electrostatic charge. For the above reasons endpoint determination is particularly critical, and it is very important to confirm that the oversize material comprises single particles and is not composed of aggregates.

2.3. Interpretation

The raw data must include the weight of test specimen, the total sieving time, and the precise sieving methodology and the set values for any variable parameters, in addition to the weights retained on the individual sieves and in the pan. It may be convenient to convert the raw data into a cumulative weight distribution, and if it is desired to express the distribution in terms of a cumulative weight undersize, the range of sieves used should include a sieve through which all the material passes. If there is evidence on any of the test sieves that the material remaining on it is composed of aggregates formed during the sieving process, the analysis is invalid.

4. Biological Tests/Biochemical Tests/Microbial Tests

4.01 Bacterial Endotoxins Test

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia.

Bacterial Endotoxins Test is a test to detect or quantify bacterial endotoxins of gram-negative bacterial origin using a lysate reagent prepared from blood corpuscle extracts of horseshoe crab (Limulus polyphemus or Tachypleus tridentatus). There are two types of techniques for this test: the gel-clot techniques, which are based on gel formation by the reaction of the lysate TS with endotoxins, and the photometric techniques, which are based on endotoxin-induced optical
changes of the lysate TS. The latter include turbidimetric techniques, which are based on the change in lysate TS turbidity during gel formation, and chromogenic techniques, which are based on the development of color after cleavage of a synthetic peptide-chromogen complex.

Once any one of these techniques for the test. In the event of doubt or dispute, the final decision is made based on gel-clot techniques, unless otherwise indicated.

The test is carried out in a manner that avoids endotoxin contamination.

1. Apparatus

Depyrogenate all glassware and other heat-stable materials in a hot-air oven using a validated process. Commonly used minimum time and temperature settings are 30 minutes at 250°C. If employing plastic apparatus, such as multi-well plates and tips for micropipettes, use only that which has been shown to be free of detectable endotoxin and which does not interfere with the test.

2. Preparation of Solutions

2.1. Preparation of Standard Endotoxin Stock Solution

Prepare Standard Endotoxin Stock Solution by dissolving Endotoxin Reference Standard that has been calibrated to the current WHO International Standard for Endotoxin, using water for bacterial endotoxins test (BET). Endotoxin is expressed in Endotoxin Units (EU). One EU is equal to one International Unit (IU) of endotoxin.

2.2. Preparation of Standard Endotoxin Solution

After mixing Standard Endotoxin Stock Solution thoroughly, prepare appropriate serial dilutions of Standard Endotoxin Solution, using water for BET. Use dilutions as soon as possible to avoid loss of activity by adsorption.

2.3. Preparation of Sample Solutions

Unless otherwise specified, prepare sample solutions by dissolving or diluting drugs, using water for BET. If necessary, adjust the pH of the solution to be examined so that the pH of the mixture of the lysate TS and sample solution falls within the specified pH range for the lysate reagent to be used. This usually applies to a sample solution with a pH in the range of 6.0 to 8.0. TSs or solutions used for adjustment of pH may be prepared using water for BET, and then stored in containers free of detectable endotoxin. The TSs or solutions must be validated to be free of detectable endotoxin and interfering factors.

3. Determination of Maximum Valid Dilution

The Maximum Valid Dilution (MVD) is the maximum allowable dilution of a sample solution at which the endotoxin limit can be determined.

Determine the MVD from the following equation:

\[
\text{MVD} = \frac{(\text{Endotoxin limit} \times \text{Concentration of sample solution})}{\lambda}
\]

Endotoxin limit:

The endotoxin limit for injections, defined on the basis of dose, equals \(K/M\), where \(K\) is a threshold pyrogenic dose of endotoxin per kg body mass (EU/kg), and \(M\) is equal to the maximum dose of product per kg body mass. When the product is to be injected at frequent intervals or infused continuously, \(M\) is the maximum total dose administered in a single hour period.

Concentration of sample solution:

mg/mL in the case of endotoxin limit specified by mass (EU/mg)

mEq/mL in the case of endotoxin limit specified by equivalent (EU/mEq)

Units/mL in the case of endotoxin limit specified by biological unit (EU/Unit)

mL/mL in the case of endotoxin limit specified by volume (EU/mL)

\(\lambda\): the labeled lysate reagent sensitivity in the gel-clot techniques (EU/mL) or the lowest point used (EU/mL) in the standard regression curve of the turbidimetric or chromogenic techniques

4. Gel-clot techniques

The gel-clot techniques detect or quantify endotoxins based on clotting of the lysate TS in the presence of endotoxin. To ensure both the precision and validity of the test, perform the tests for confirming the labeled lysate reagent sensitivity (4.1.1.) and for interfering factors (4.1.2.) as described under Preparatory testing (4.1.).

4.1. Preparatory testing

4.1.1. Test for confirmation of labeled lysate reagent sensitivity

The labeled sensitivity of lysate is defined as the lowest concentration of endotoxin that is needed to cause the lysate TS to clot under the conditions specified for the lysate to be used.

The test for confirmation of the labeled lysate sensitivity is to be carried out when each new lot of lysate is used or when there is any change in the experimental conditions which may affect the outcome of the test.

Prepare standard solutions having four concentrations equivalent to \(2\lambda\), \(\lambda\), \(0.5\lambda\) and \(0.25\lambda\) by diluting the Standard Endotoxin Stock Solution with water for BET. Mix a volume of the lysate TS with an equal volume of one of the standard solutions (usually, 0.1 mL aliquots) in each test tube. When single test vials or ampoules containing lyophilized lysate are used, add solutions directly to the vial or ampoule.

Keep the tubes (or containers such as vials or ampoules) containing the reaction mixture usually at 37 ± 1°C for 60 ± 2 minutes, avoiding vibration. To test the integrity of the gel after incubation, invert each tube or container through approximately 180° in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if either a firm gel is not formed, or if a fragile gel has formed but flows out on inversion.

Making the standard solutions of four concentrations one set, test four replicates of the set.

The test is valid when 0.25\(\lambda\) of the standard solution shows a negative result in each set of tests. If the test is not valid, repeat the test after verifying the test conditions.

The endpoint is the last positive test in the series of decreasing concentrations of endotoxin. Calculate the geometric mean endpoint concentration of the four replicate series using the following formula:

\[
\text{Geometric Mean Endpoint Concentration} = \text{antilog} \left( \frac{\Sigma e}{f} \right)
\]

\(\Sigma e\) = the sum of the log endpoint concentrations of the dilution series used

\(f\) = the number of replicates

If the geometric mean endpoint concentration is not less
than 0.5 \( \lambda \) and not more than 2.0 \( \lambda \), the labeled sensitivity is confirmed, and is used in tests performed with this lysate.

4.1.2. Test for interfering factors

This test is performed to check for the presence of enhancing or inhibiting factors in the reaction in sample solutions. Prepare the solutions A, B, C and D according to Table 4.01-1, and test solutions A and B and solutions C and D in quadruplicate and in duplicate, respectively. Concerning the incubation temperature, incubation time, and procedure for the confirmation of gel formation, follow the procedure described in 4.1.1.

The geometric mean endpoint concentrations of B and C solutions are determined by using the formula described in 4.1.1.

This test must be repeated when there is any change in the experimental conditions which may affect the outcome of the test. The test is valid if solutions A and D show no reaction and the result for solution C confirms the labeled sensitivity. If the geometric mean endpoint concentration of solution B is not less than 0.5 \( \lambda \) and not greater than 2.0 \( \lambda \), the sample solution examined does not contain interfering factors and complies with the test for interfering factors. Otherwise the sample solution interferes with the test.

If the sample under test does not comply with the test at a dilution less than the MVD, repeat the test using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a grater dilution of the sample to be examined. Furthermore, interference of the sample solution or diluted sample solution may be eliminated by suitable treatment, such as filtration, neutralization, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, perform the assay described above using the preparation to be examined to which Standard Endotoxin has been added and which has then been submitted to the chosen treatment.

4.2. Limit test

This method tests whether or not a sample contains endotoxins greater than the endotoxin limit specified in the individual monograph based on the gel formation in the presence of endotoxins at a concentration of more than the labeled lysate sensitivity.

4.2.1. Procedure

Prepare solutions A, B, C and D according to Table 4.01-1. This test is performed to check for the presence of enhancing or inhibiting factors in the reaction in sample solutions. Prepare the solutions A, B, C and D according to Table 4.01-1, and test solutions A and B and solutions C and D in quadruplicate and in duplicate, respectively. Concerning the incubation temperature, incubation time, and procedure for the confirmation of gel formation, follow the procedure described in 4.1.1.

4.2.2. Interpretation

The test is valid when both replicates of solutions B and C are positive and those of solution D are negative. When a negative result is found for both replicates of solution A, the sample complies with the Bacterial Endotoxins Test. When a positive result is found for both replicates of solution A, the sample does not comply with the test. When a positive result is found for one replicate of solution A and a negative result is found for the other, repeat the test. In the repeat test, the sample complies with the test if a negative result is found for both replicates of solution A. The sample does not comply with the test if a positive result is found for one or both replicates of solution A. However, if the sample does not comply with the test at a dilution less than the MVD, the test may be repeated using a grater dilution, not exceeding the MVD.

4.3. Quantitative Test

This method measures endotoxin concentrations of samples by determining an endpoint of gel formation.

4.3.1. Procedure

Prepare solutions A, B, C and D according to Table 4.01-1. This test is performed to check for the presence of enhancing or inhibiting factors in the reaction in sample solutions. Prepare the solutions A, B, C and D according to Table 4.01-1. This test is performed to check for the presence of enhancing or inhibiting factors in the reaction in sample solutions. Prepare the solutions A, B, C and D according to Table 4.01-1, and test solutions A and B and solutions C and D in quadruplicate and in duplicate, respectively. Concerning the incubation temperature, incubation time, and procedure for the confirmation of gel formation, follow the procedure described in 4.1.1.

4.3.2. Calculation and interpretation

The test is valid when the following three conditions are met: (a) both replicates of the negative control solution D are negative, (b) both replicates of the positive product control solution B are positive and (c) the geometric mean endpoint concentration of solution C is in the range of 0.5 \( \lambda \) to 2 \( \lambda \). The endpoint is defined as the maximum dilution showing a positive result for both replicates of solution A, the sample complies with the Bacterial Endotoxins Test. When a negative result is found for both replicates of solution A, the sample does not comply with the test. When a positive result is found for one replicate of solution A and a negative result is found for the other, repeat the test. In the repeat test, the sample complies with the test if a positive result is found for both replicates of solution A. The sample does not comply with the test if a negative result is found for one or both replicates of solution A. However, if the sample does not comply with the test at a dilution less than the MVD, the test may be repeated using a grater dilution, not exceeding the MVD.

*1 Sample solution for the limit test. The solution may be diluted not to exceed the MVD.
*2 Positive control. Sample solution at the same dilution as solution A, containing standard endotoxin at a concentration of 2l.
*3 Positive control. Standard endotoxin solution containing standard endotoxin concentration of 2l.
*4 Negative control. Water for BET only.
The endotoxin concentration of the sample solution. The sample complies with the Bacterial Endotoxins Test if the endotoxin concentration of the sample solution.

The kinetic-turbidimetric technique is based on the quantitative relationship between the concentration of endotoxins and the turbidity of the reaction mixture at a specified reaction time.

The kinetic-turbidimetric technique is based on the quantitative relationship between the concentration of endotoxins and the turbidity of the reaction mixture or the rate of color development.

The test is usually carried out at 37 ± 1°C.

5.3. Preparatory testing

To assure the precision and validity of the turbidimetric or chromogenic techniques, perform both Test for assurance of criteria for the standard curve (5.3.1.) and Test for interfering factors (5.3.2.), as indicated below.

5.3.1. Test for assurance of criteria for the standard curve

The test is to be carried out when each new lot of lysate reagent is used or when there is any change in the experimental conditions which may affect the outcome of the test.

Using the Standard Endotoxin Solution, prepare at least three endotoxin concentrations to generate the standard curve within the range of endotoxin concentrations indicated by the instructions for the lysate reagent used. Perform the test using at least three replicates of each standard endotoxin concentration according to the optimal conditions for the lysate reagent used (with regard to volume ratios, incubation time, temperature, pH, etc.). If the desired range is greater than two logs, additional standards should be included to bracket each log increase in the range of the standard curve.

If the absolute value of the correlation coefficient, |r|, is greater than or equal to 0.980 for the range of endotoxin concentrations set up, the criteria for the standard curve are valid and the curve complies with the test.

If the standard curve does not comply with the test, repeat the test after verifying the test conditions.

5.3.2. Test for interfering factors

Prepare solutions A, B, C and D according to Table 4.01-4. Perform the test on these solutions following the optimal conditions for the lysate reagent used (with regard to volume of sample solution and lysate TS, volume ratio of sample solution to lysate TS, incubation time, etc.).

The test for interfering factors must be repeated when any condition changes, which is likely to influence the result of the test.

The test is valid when the following conditions are met.

1: The absolute value of the correlation coefficient of the standard curve generated using solution C is greater than or equal to 0.980.

2: The result with solution D does not exceed the limit of the blank value required in the description of the lysate employed, or it is less than the endotoxin detection limit of the lysate employed.

Calculate the recovery of the endotoxin added to solution B from the concentration found in solution B after subtracting the endotoxin concentration found in solution A.

When the recovery of the endotoxin added to solution B is within 50% to 200%, the sample solution under test is considered to be free of interfering factors and the solution complies with the test.

When the endotoxin recovery is out of the specified range,
the sample solution under test is considered to contain interfering factors. If the sample under test does not comply with the test, repeat the test using a greater dilution, not exceeding the MVD. Furthermore, interference of the sample solution or diluted sample solution not to exceed the MVD may be eliminated by suitable treatment, such as filtration, neutralization, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, perform the assay described above using the preparation to be examined to which Standard Endotoxin has been added and which has then been submitted to the chosen treatment.

5.4. Quantitative test

5.4.1. Procedure

Prepare solutions A, B, C and D according to Table 4.01-4, and follow the procedure described in 5.3.2.

5.4.2. Calculation of endotoxin concentration

Calculate the mean endotoxin concentration of solution A using the standard curve generated with solution C. The test is valid when all the following requirements are met.

1. The absolute value of the correlation coefficient of the standard curve generated using solution C is greater than or equal to 0.980.
2. The endotoxin recovery, calculated from the concentration found in solution B after subtracting the concentration of endotoxin found in solution A, is within the range of 50% to 200%.
3. The result with solution D does not exceed the limit of the blank value required in the description of the lysate employed, or it is less than the endotoxin detection limit of the lysate employed.

5.4.3. Interpretation

The sample complies with the Bacterial Endotoxins Test if the endotoxin concentration of the sample calculated from the mean endotoxin concentration of solution A meets the requirement of the endotoxin limit (in EU/mL, EU/mg, EU/mEq or EU/Unit) specified in the individual monograph.

4.02 Microbial Assay for Antibiotics

Microbial Assay for Antibiotics is a method to determine the antimicrobial potency of antibiotics based on their antimicrobial activities. There are three methods for this test: the cylinder-plate, perforated plate, and turbidimetric methods. The former two are based on the measurement of the size of the zones of microbial growth inhibition in a nutrient agar medium, and the turbidimetric method is based on the measurement of the inhibition of turbidity development in a fluid medium with microbial growth. Unless otherwise specified in the individual monograph, tests specified to be carried out by the cylinder-plate method may be conducted under the same test conditions using the perforated plate method instead. If necessary, first sterilize water, isotonic sodium chloride solution, buffer solutions, reagents, test solutions and essential parts of measuring instruments and appliances to be used for the test. In performing the test, precautions must be taken to prevent biohazard.

1. Cylinder-plate method

The cylinder-plate method is a method to determine the antimicrobial potency of the antibiotic to be tested, and is based on the measurement of the size of the zone of growth inhibition of a test organism by the use of cylinder-agar plates.

1.1. Test organisms

Use the test organism specified in the individual monograph.

1.2. Culture media

Unless otherwise specified, use media with the following compositions. When ‘peptone’ is indicated as an ingredient of a medium, either meat peptone or casein peptone is applicable. Use sodium hydroxide TS or 1 mol/L hydrochloric acid TS to adjust the pH of the medium to obtain the specified value after sterilization. In the case of the medium for Bacillus subtilis ATCC 6633, adjust the pH using ammonia TS, potassium hydroxide TS or 1 mol/L hydrochloric acid TS. A different medium to the one specified for each test organism may be used if it has both a similar composition and an equal or better growth efficiency of the test organism in comparison with the specified medium. Unless otherwise specified, sterilize the media to be used in an autoclave.

(i) Agar media for seed and base layer

1. Media for test organism Bacillus subtilis ATCC 6633

i. Peptone 5.0 g
Meat extract 3.0 g
Agar 15.0 g
Water 1000 mL

Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 7.8 to 8.0 after sterilization.

ii. Peptone 5.0 g
Meat extract 3.0 g
Trisodium citrate dihydrate 10.0 g
Agar 15.0 g
Water 1000 mL

Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.5 to 6.6 after sterilization.

2. Medium for test organism Saccharomyces cerevisiae ATCC 9763
Glucose 10.0 g
Peptone 9.4 g
Meat extract 2.4 g
Yeast extract 4.7 g
Sodium chloride 10.0 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.0 to 6.2 after sterilization.

3) Media for other organisms
i. Glucose 1.0 g
Peptone 6.0 g
Meat extract 1.5 g
Yeast extract 3.0 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.5 to 6.6 after sterilization.

ii. Glucose 1.0 g
Meat peptone 6.0 g
Casein peptone 4.0 g
Meat extract 1.5 g
Yeast extract 3.0 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.5 to 6.6 after sterilization.

iii. Peptone 10.0 g
Meat extract 5.0 g
Sodium chloride 2.5 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.5 to 6.6 after sterilization.

(2) Agar media for transferring test organisms
1) Medium for test organism Saccharomyces cerevisiae
ATCC 9763
Glucose 15.0 g
Peptone 5.0 g
Yeast extract 2.0 g
Magnesium sulfate heptahydrate 0.5 g
Potassium dihydrogen phosphate 1.0 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.0 to 6.2 after sterilization.

2) Media for other organisms
i. Glucose 1.0 g
Meat peptone 6.0 g
Casein peptone 4.0 g
Meat extract 1.5 g
Yeast extract 3.0 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.5 to 6.6 after sterilization.

ii. Peptone 10.0 g
Meat extract 5.0 g
Sodium chloride 2.5 g
Agar 15.0 g
Water 1000 mL
Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 6.5 to 6.6 after sterilization.

1.3. Preparation of agar slant or plate media

Unless otherwise specified, dispense approximately 9 mL of melted agar medium in each test tube (approximately 16 mm in inside diameter), and make them as slant media, or dispense approximately 20 mL of melted agar medium in each Petri dish (approximately 90 mm in inside diameter), and make them as plate media.

1.4. Preparation of stock suspensions of test spores or organisms

Unless otherwise specified, prepare stock suspensions of test spore or organism cultures as follows. Check the aspects of the test spores or organisms as occasion demands.

(i) Preparation of a stock spore suspension of test organism Bacillus subtilis ATCC 6633

Inoculate the test organism onto the slant or plate of the agar medium which was prepared for transferring the test organisms specified in 2 (2) i. Incubate at 32 to 37°C for 16 to 24 hours. Inoculate the subcultured test organism onto a suitable volume of slant or plate of the agar medium (described above), which was prepared for transferring the test organisms specified in 2 (2) ii. Then incubate at 32 to 37°C for not less than 1 week to prepare spores. Suspend the spores in isotonic sodium chloride solution, heat at 65°C for 30 minutes, and then centrifuge. Wash the spore sediment three times with isotonic sodium chloride solution by means of centrifugation. Re-suspend the spore sediment in water or isotonic sodium chloride solution, and heat again at 65°C for 30 minutes to prepare the stock spore suspension. The concentration of the test organism is confirmed with the turbidity or absorbance, as occasion demands. Store the stock spore suspension at a temperature not exceeding 5°C, and use within 6 months. If the stock spore suspension shows a clear and definite zone of growth inhibition in an antibiotics potency test using adequate antibiotics, it may be used for further 6 months.

(ii) Preparation of a stock suspension of the test organism Saccharomyces cerevisiae ATCC 9763

Inoculate test organism onto the slant or plate agar medium which has been prepared for transferring test organism specified in 2 (2) 1. Incubate at 25 to 26°C for 40 to 48 hours. The subculture should be performed at least three times. Inoculate the subcultured test organism onto another slant or plate of the agar medium (described above), and incubate at 25 to 26°C for 40 to 48 hours. Scrape away and suspend the resulting growth from the agar surface in isotonic sodium chloride solution, and use this as a stock suspension of the test organism. The concentration of the test organism is confirmed with the turbidity or absorbance, as occasion demands. Store the stock suspensions of the test organisms at a temperature not exceeding 5°C, and use within 30 days.

(iii) Preparation of a stock suspension of other test organisms

Inoculate the test organism onto the slant or the plate of the agar medium which has been prepared for transferring the test organisms specified in 2 (2) 1. Incubate the inoculated slant at 32 to 37°C for 16 to 24 hours. The subculture should be performed at least three times. Inoculate the subcultured test organism onto another slant or plate agar medium (described above), and incubate the slant at 32 to 37°C for 16 to 24 hours. Scrape away and suspend the resulting growth from the agar surface in isotonic sodium chloride solution, and use this as a stock suspension of the test organism.
ism. The concentration of the test organism is confirmed with turbidity or absorbance, as occasion demands. Store the stock suspensions of the test organisms at a temperature not exceeding 5°C, and use within 5 days.

1.5. Preparation of agar base layer plates

Unless otherwise specified, dispense 20 mL of the melted agar medium for the base layer into each Petri dish, and in the case of a large dish, dispense a quantity of the agar medium to form a uniform layer 2 to 3 mm thick. Distribute the agar evenly in each dish on a flat, level surface, and allow it to harden.

1.6. Preparation of seeded agar layers

Unless otherwise specified, determine the volume of the stock suspension of the spore or the test organism with which the employed standard solution shows a clear and definite zone of growth inhibition. Prepare the seeded agar layer by mixing thoroughly the previously determined volume of stock suspension of spore or test organism with agar medium for the seed layer kept at 48 to 51°C. Usually, the rate of a stock spore suspension and a stock suspension of the test organisms at a temperature not exceeding 5°C, respectively.

1.7. Preparation of cylinder-agar plates

Dispense 4 to 6 mL of the seeded agar layer, which is specified in the individual monograph, on an agar base layer plate in a Petri dish. In the case of large dishes, dispense a quantity of the agar medium to form a uniform layer 1.5 to 2.5 mm thick, and spread evenly over the surface before hardening. After coagulating the agar, allow the plate to stand under a clean atmosphere to exhale moisture vapor of the inside of Petri or large dishes and water on the agar surface. Place 4 cylinders on an agar plate in a Petri dish so that the individual cylinders are equidistant from the center of the plate and equally spaced from one another (the cylinders are set on the circumference of a circle of 25 to 28 mm radius). When large dish plates are used, place cylinders on each plate according to the method of preparation for Petri dish agar plates. A set of 4 cylinders on each large dish plate is considered to be equivalent to one Petri dish plate. Use stainless steel cylinders with the following dimensions: outside diameter 7.9 to 8.1 mm; inside diameter 5.9 to 6.1 mm; length 9.9 to 10.1 mm. The cylinders should not interfere with the test. Prepare the cylinder-agar plates before use.

1.8. Standard solutions

Use both a standard solution of high concentration and one of low concentration, as specified in the individual monograph. Unless otherwise specified, prepare the standard solutions before use.

1.9. Sample solutions

Use both a sample solution of high concentration and one of low concentration, as specified in the individual monograph. Unless otherwise specified, prepare the sample solutions before use.

1.10. Procedure

Unless otherwise specified, use 5 cylinder-agar plates as one assay set when Petri dishes are employed. When large dishes are employed, the number of cylinders for one assay set should be equal to that defined when using Petri dishes. Apply the standard solution of high concentration and that of low concentration to a pair of cylinders set opposite each other on each plate. Apply the high and low concentration sample solutions to the remaining 2 cylinders. The same volume of these solutions must be added to each cylinder.

Incubate the plates at 32 to 37°C for 16 to 20 hours. Using a suitable measuring tool, measure the diameters of circular inhibition zones with a precision that can discriminate differences of at least 0.25 mm. Each procedure should be performed quickly under clean laboratory conditions.

1.11. Estimation of potency

The following correlation between the potency (P) of solution in a cylinder and the diameter (d) of zone of inhibition is established.

\[ d = \alpha \log P + \beta \]

where, \( \alpha \) and \( \beta \) are constants.

If necessary, ascertain the values in the above equation. Based on this equation, estimate the potency of the sample solutions by application of the following equation:

\[ \text{Amount (potency) of sample} = A \times \text{Potency of } S_H \text{ per mL} \times \text{Dilution factor of } U_H \]

where:

\[ \text{log} A = \frac{IV}{W} \]

\[ I = \log (\text{potency of } S_H/\text{potency of } S_L) \]

\[ V = 2(U_H + U_U - U_H - U_L) \]

\[ W = 2(U_H + 2U_U - 2U_L - U_L) \]

The sum of the diameter (mm) of the inhibitory zone measured in each plate is designated as follows:

- for standard solution of high concentration \((S_{SH}) = 2S_H\)
- for standard solution of low concentration \((S_{SL}) = 2S_L\)
- for sample solution of high concentration \((U_{SH}) = 2U_H\)
- for sample solution of low concentration \((U_{SL}) = 2U_L\)

2. Perforated plate method

The perforated plate method is a method to determine the antimicrobial potency of an antibiotic, based on the measurement of the size of the zone of growth inhibition of a test organism by the use of perforated agar plates.

This method is carried out by the use of perforated agar plates in lieu of cylinder-agar plates used in Cylinder-plate method.

Proceed as directed below, but comply with the requirements of Cylinder-plate method, such as test organisms, media, preparation of agar slant or plate media, preparation of stock suspensions of spores or test organisms, preparation of agar base layer plates, preparation of seeded agar layers, standard solutions, sample solutions, and estimation of potency.

2.1. Preparation of perforated agar plates

Dispense 4 to 6 mL of the seeded agar layer specified in the individual monograph on each agar base layer plate of the Petri dish. In the case of large dishes, dispense a quantity of the agar medium to form a uniform layer 1.5 to 2.5 mm thick, and spread evenly over the surface before hardening. After coagulating the agar, allow the plate to stand under a clean atmosphere to exhale moisture vapor of the inside of Petri or large dishes and water on the agar surface. Using a suitable tool, prepare 4 circular cavities having a diameter of 7.9 to 8.1 mm on a Petri dish agar plate so that the individual cylinders are equidistant from the center of the plate and equally spaced from one another on the circumference of a circle with radius 25 to 28 mm, and are deep enough to reach the bottom of dish. When large dish plates are used, prepare the circular cavities on each plate accord-
ing to the method of preparation for Petri dish agar plates. A set of 4 cavities on each large dish plate is considered to be equivalent to one Petri dish plate. Prepare the perforated agar plates before use.

2.2. Procedure

Unless otherwise specified, use 5 perforated agar plates as one assay set when Petri dishes are employed. When large dishes are employed, the number of cavities for one assay set should be equal to that defined when using Petri dishes. Apply the high and low concentration standard solutions to a pair of cavities prepared opposite each other on each plate, and apply the high and low concentration sample solutions to the remaining 2 cavities. The same volume of these solutions must be added to each cavity. Incubate the plates at 32 to 37°C for 16 to 20 hours. Using a suitable measuring tool, measure the diameters of the circular inhibition zones with a precision that can discriminate differences of at least 0.25 mm. Each procedure should be performed quickly under clean laboratory conditions.

3. Turbidimetric method

The turbidimetric method is a method to determine the antimicrobial potency of an antibiotic, based on the measurement of the inhibition of growth of a microbial culture in a fluid medium. The inhibition of growth of a test organism is photometrically measured as changes in turbidity of the microbial culture.

3.1. Test organisms

Use the test organism specified in the individual monograph.

3.2. Culture media

Unless otherwise specified, use media with the following compositions. When peptone is indicated as an ingredient of a medium, either meat peptone or casein peptone is applicable. Use sodium hydroxide TS or 1 mol/L hydrochloric acid TS to adjust the pH of the medium to obtain the specified value after sterilization. A different medium to the one specified for each test organism may be used if it has both a similar composition and an equal or better growth efficiency of the test organism in comparison with the specified medium. Unless otherwise specified, sterilize the media to be used in an autoclave.

(1) Agar media for transferring test organisms

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Glucose</td>
<td>1.0 g</td>
</tr>
<tr>
<td>Peptone</td>
<td>6.0 g</td>

</tr>
</tbody>
</table>

Mix all the ingredients, and sterilize. Adjust the pH of the solution so that it will be 7.0 to 7.1 after sterilization.

* Dipotassium hydrogen phosphate (3.68 g) may be used in lieu of disodium hydrogen phosphate (3.0 g).

3.3. Preparation of agar slant or plate media

Unless otherwise specified, proceed as directed in Preparation of agar slant or plate media under Cylinder-plate method.

3.4. Preparation of stock suspensions of test organisms

Unless otherwise specified, inoculate the test organism onto the slant or plate of the agar medium which was prepared for transferring the specified test organism. Incubate the inoculated medium at 32 to 37°C for 16 to 24 hours. The subculture should be performed at least three times. Check the aspects of the test spores or organisms as occasion demands. Inoculate the subcultured test organism onto another slant or plate of the agar medium (described above), and incubate the slant at 32 to 37°C for 16 to 24 hours. After incubation, suspend the test organism in the liquid medium for suspending the test organism, and use as the suspension of the test organism. The concentration of the test organism is confirmed with the turbidity or absorbance, as occasion demands.

3.5. Standard solutions

Use the standard solutions specified in the individual monograph. Unless otherwise specified, prepare the standard solutions before use.

3.6. Sample solutions

Use the sample solutions specified in the individual monograph. Unless otherwise specified, prepare the sample solutions before use.

3.7. Procedure

Unless otherwise specified, proceed as follows:

Distribute 1.0 mL of each concentration of the standard solution, the sample solution, and water used as a control, into each set composed of 3 test tubes (about 14 mm in inside diameter and about 13 cm in length). Add 9.0 mL of the suspension of the test organism to each tube, and then incubate in a water bath maintained at 35 to 37°C for 3 to 4 hours. After incubation, add 0.5 mL of dilute formaldehyde (1 in 3) to each tube, and read each transmittance or absorbance at a wavelength of 530 nm.

3.8. Estimation of potency

Average the transmittance or absorbance values of each concentration of the standard solution, the sample solution and water used as a control, respectively. Generate the standard curve based on the average values of transmittance or absorbance of each concentration of the standard solution, and estimate the potency of the sample solution from its average value of transmittance or absorbance using the obtained standard curve.

If the standard dilutions of five concentrations in geometric progression are used, calculate the L and H values from the following equations. Plot point L and point H on graph paper and construct a straight line for the standard curve.

\[
L = \frac{3a + 2b + c - e}{5}
\]

\[
H = \frac{3e + 2d + c - a}{5}
\]

where:

L = calculated value of transmittance or absorbance for the lowest concentration of the standard curve.

H = calculated value of transmittance or absorbance for
4.03 Digestion Test

Digestion Test is a test to measure the activity of digestive enzymes, as crude materials or preparations, on starch, protein and fat.

1. Assay for Starch Digestive Activity

The assay for starch digestive activity is performed through the measurement of starch saccharifying activity, dextrinizing activity, and liquefying activity.

1.1. Measurement of starch saccharifying activity

The starch saccharifying activity can be obtained by measuring an increase of reducing activity owing to the hydrolysis of the glucoside linkages when amylase acts on the starch. Under the conditions described in Procedure, one starch saccharifying activity unit is the amount of enzyme that catalyzes the increase in reducing activity equivalent to 1 mg of glucose per minute.

1.1.1. Preparation of Sample Solution

Dissolve the sample in an appropriate amount of water, or a buffer or salts solution specified in the monograph so that the reducing activity increases in proportion to the concentration of the sample solution, when measuring under the conditions described in Procedure. The concentration is normally 0.4 to 0.8 starch saccharifying activity unit/mL. Filter if necessary.

1.1.2. Preparation of Substrate Solution

Use potato starch TS for measuring the starch digestive activity. If necessary, add 10 mL of buffer or salts solution specified in the monograph, instead of 10 mL of 1 mol/L acetic acid-sodium acetate buffer solution, pH 5.0.

1.1.3. Procedure

Pipet 10 mL of the substrate solution, stand at 37 ± 0.5°C for 10 minutes, add exactly 1 mL of the sample solution, and shake immediately. Allow this solution to stand at 37 ± 0.5°C for exactly 10 minutes, add exactly 2 mL of alkaline trtarate solution of the Fehling’s TS for amylolytic activity test, shake gently, heat the solution in a water bath for exactly 15 minutes, and then immediately cool to below 25°C. Then, add exactly 2 mL of concentrated potassium iodide TS and 2 mL of diluted sulfuric acid (1 in 6), and titrate the released iodine with 0.05 mol/L sodium thiosulfate VS to the disappearance of the blue color produced by addition of 1 to 2 drops of soluble starch TS (a mL). Separately, pipet 10 mL of water instead of the substrate solution and titrate the starch saccharifying activity (unit/g)

\[
\text{Starch saccharifying activity} = \frac{1}{10} \times \frac{1}{M} \times (b - a)
\]

Amount (mg) of glucose = (b - a) × 1.6

\[M: \text{Amount (g) of sample in 1 mL of sample solution}\]

1.2. Measurement of starch dextrinizing activity

The starch dextrinizing activity can be obtained by measuring a decrease in starch coloration by iodine resulting from hydrolysis of the straight chain component (amylose) in starch when amylase acts on the starch. Under the conditions described in Procedure, one starch dextrinizing activity unit is the amount of enzyme required to reduce the coloration of potato starch by iodine by 10% per minute.

1.2.1. Preparation of Sample Solution

Dissolve the sample in an appropriate amount of water or a buffer or salts solution specified in the monograph so that the coloration of starch by iodine decreases in proportion to the concentration of the sample solution, when measuring under the conditions described in Procedure. The concentration is normally 0.2 to 0.5 starch dextrinizing activity unit/mL. Filter if necessary.

1.2.2. Preparation of Substrate Solution

Prepare the substrate solution in the same manner as the substrate solution in the measurement of starch saccharifying activity.

1.2.3. Procedure

Pipet 10 mL of the substrate solution, stand at 37 ± 0.5°C for 10 minutes, add exactly 1 mL of the sample solution, and shake immediately. Allow this solution to stand at 37 ± 0.5°C for exactly 10 minutes. Pipet 1 mL of this solution, add it to 10 mL of 0.1 mol/L hydrochloric acid TS, and shake immediately. Pipet 0.5 mL of this solution, add exactly 10 mL of 0.0002 mol/L iodine TS, and shake. Determine the absorbance \(A_r\) of this solution at the wavelength of 660 nm as directed under Ultraviolet-visible Spectrophotometry (2.24). Separately, using 1 mL of water instead of the sample solution, determine the absorbance \(A_b\) in the same manner.

\[
\text{Starch dextrinizing activity} = \frac{(A_b - A_r)}{A_b} \times \frac{1}{M}
\]

\[M: \text{Amount (g) of sample in 1 mL of sample solution}\]

1.3. Measurement of starch liquefying activity

The starch liquefying activity can be obtained by measuring a decrease in the viscosity of starch solution resulting from the hydrolysis of molecules when amylase acts on the starch. Under the conditions described in Procedure, one starch liquefying activity unit is the amount of enzyme required to reduce the viscosity of the substrate solution equivalent to 1 g of potato starch from 200% to 100% of that of the 50% sucrose standard solution.

1.3.1. Preparation of Sample Solution

Dissolve the sample in an appropriate amount of water, or a buffer or salts solution specified in the monograph so that the viscosity decreases in proportion to the concentration of the sample solution, when measuring under the conditions described in Procedure. The concentration is normally 0.15 to 0.25 starch liquefying activity unit/mL. Filter if necessary.
1.3.2. Preparation of Substrate Solution

Weigh accurately about 1 g of potato starch, and measure the loss of drying at 105°C for 2 hours. Weigh exactly potato starch equivalent to 15.00 g calculated on the dried basis, add 300 mL of water, then add gradually 25 mL of 2 mol/L sodium hydroxide TS under thorough shaking, until the mixture forms a paste. Heat the mixture in a water bath for 10 minutes, shaking it occasionally. After cooling, neutralize the mixture with 2 mol/L hydrochloric acid TS, and add 50 mL of the buffer solution specified in the monograph and water to make exactly 500 g. Prepare before use.

1.3.3. Preparation of 50% Standard Sucrose Solution

Dissolve 50.0 g of sucrose in 50.0 mL of water.

1.3.4. Procedure

Put 50 mL of the 50% standard sucrose solution in a 100-mL conical flask, and allow it to stand in a thermostat at 37 ± 0.5°C for 15 minutes. Fix a viscometer shown in Fig. 4.03-1 so that its lower end almost touches the bottom of the flask and that the water in the thermostat circulates around the outer cylinder of the viscometer. After slowly pulling up the 50% standard sucrose solution by suction to the middle of the upper bulb of the viscometer, let it flow down by gravity, measuring the time taken for the solution to fall from the upper to the lower indicators (t1; seconds). Take exactly 50 g of the substrate solution in another 100-mL conical flask, and stand it in another thermostat at 37 ± 0.5°C for 20 minutes. Add exactly 1 mL of the sample solution to it, and shake the flask immediately. Fix a viscometer vertically so that its lower end almost touches the bottom of the flask and that the water in the thermostat circulates around the outer cylinder of the viscometer. Occasionally pull the reaction solution up by suction to the middle of the upper bulb slowly, then let it flow down by gravity, measuring the time taken for the solution to fall from the upper to the lower indicators (t seconds).

Repeat this operation until t becomes shorter than t1. At each measurement, record the time (T′) from the moment that the sample solution is added to the moment that the solution surface in the flask passes the upper indicator. (T′ + t/2) is the reaction time (T) corresponding to t. Draw a curve for both t and T. Obtain T1 and T2 that correspond to t1 and (2 × t1) by interpolation.

Starch liquefying activity (unit/g) = \[ \frac{60}{(T1 - T2)} \times \frac{1.5}{M} \]

M: Amount (g) of sample in 1 mL of sample solution

2. Assay for Protein Digestive Activity

The protein digestive activity can be obtained by the colorimetric measurement, making use of Folin’s reaction, of the amount of acid-soluble low-molecular products, which is increased owing to the hydrolysis of the peptide linkages when protease acts on casein. One protein digestive activity unit is the amount of enzymes that produces Folin’s TS-colorable substance equivalent to 1 μg of tyrosine per minute under the conditions described in Procedure.

2.1. Preparation of Sample Solution

Dissolve the sample in an appropriate amount of water, or a buffer or salts solution specified in the monograph so that the amount of non-protein, Folin’s TS-colorable substances increase in proportion to the concentration of the sample solution, when measuring under the conditions described in Procedure. The concentration is normally 15 to 30 protein digestive activity unit/mL.

2.2. Tyrosine Calibration Curve

Weigh exactly 50 mg of Tyrosine Reference Standard, previously dried at 105°C for 3 hours, and dissolve in 0.2 mol/L hydrochloric acid TS to make exactly 50 mL. Pipet 1 mL, 2 mL, 3 mL and 4 mL of this solution separately, and add 0.2 mol/L hydrochloric acid TS to each solution to make them exactly 100 mL. Pipet 2 mL of each solution, and add exactly 5 mL of 0.55 mol/L sodium carbonate TS and 1 mL of diluted Folin’s TS (1 in 3) to each solution, shake immediately, then stand them at 37 ± 0.5°C for 30 minutes. Determine the absorbances, A1, A2, A3, and A4, of these solutions at 660 nm as directed under Ultraviolet-visible Spectrophotometry <2.2A>, using a solution prepared with exactly 2 mL of 0.2 mol/L hydrochloric acid TS in the same manner as the blank. Then, draw a calibration curve with the absorbances, A1, A2, A3, and A4 as the ordinate, and with the amount (μg) of tyrosine in 2 mL of each solution as the abscissa. Obtain the amount (μg) of tyrosine for the absorbance 1.

2.3. Preparation of Substrate Solution

(i) Substrate solution 1: Weigh accurately about 1 g of milk casein, and measure the loss on drying at 105°C for 2 hours. Weigh exactly an amount of milk casein equivalent to 1.20 g calculated on the dried basis, add 12 mL of lactic acid TS and 150 mL of water, and warm to dissolve in a water bath. After cooling in running water, adjust to the pH specified in the monograph with 1 mol/L hydrochloric acid TS or sodium hydroxide TS, and add water to make exactly 200 mL. Prepare before use.

(ii) Substrate solution 2: Weigh accurately about 1 g of milk casein, and measure the loss on drying at 105°C for 2
hours. Weigh exactly an amount of milk casein equivalent to 1.20 g calculated on the dried basis, add 160 mL of 0.05 mol/L disodium hydrogenphosphate TS, and warm to dissolve in a water bath. After cooling in running water, adjust to the pH specified in the monograph with the 1 mol/L hydrochloric acid TS or sodium hydroxide TS, and add water to make exactly 200 mL. Prepare before use.

2.4. Preparation of Precipitation Reagent
(i) Trichloroacetic acid TS A: Dissolve 7.20 g of trichloroacetic acid in water to make 100 mL.
(ii) Trichloroacetic acid TS B: Dissolve 1.80 g of trichloroacetic acid, 1.80 g of anhydrous sodium acetate and 5.5 mL of 6 mol/L acetic acid TS in water to make 100 mL.

2.5. Procedure
Pipet 5 mL of the substrate solution specified in the monograph, stand at 37 ± 0.5°C for 10 minutes, add exactly 1 mL of the sample solution, and shake immediately. After standing this solution at 37 ± 0.5°C for exactly 10 minutes, add exactly 5 mL of trichloroacetic acid TS A or B as specified in the monograph, shake, stand it at 37 ± 0.5°C for 30 minutes, and then filter. Discard the first 3 mL of the filtrate, exactly measure the subsequent 2 mL of the filtrate, and determine the absorbance \( A_T \) of this solution at 660 nm as directed under Ultraviolet-visible Spectrophotometry \(<2.24>\), using water as the blank. Separately, pipet 1 mL of the sample solution, add exactly 5 mL of trichloroacetic acid TS A or B to the solution as specified in the monograph, and shake. To this solution add exactly 5 mL of the substrate solution specified in the monograph, shake immediately, and stand it at 37 ± 0.5°C for 30 minutes. Follow the same procedure for the sample solution, and determine the absorbance \( A_B \) at 660 nm.

**Protein digestive activity (unit/g)**

\[
\text{Protein digestive activity (unit/g)} = \frac{(A_T - A_B) \times F \times 11/2 \times \frac{1}{10} \times \frac{1}{M}}{M}
\]

**M:** Amount (g) of sample in 1 mL of sample solution
**F:** Amount (\( \mu g \)) of tyrosine for absorbance 1 determined from Tyrosine Calibration Curve

3. Assay for Fat Digestive Activity

The fat digestive activity can be obtained by back titration of the amount of fatty acid produced from the hydrolysis of the ester linkage, when lipase acts on olive oil. One fat digestive activity unit is the amount of enzymes that produces 1 \( \mu \)mole of fatty acid per minute under the conditions described in Procedure.

3.1. Preparation of Sample Solution

Dissolve or suspend the sample in an appropriate amount of cold water, or a buffer or salts solution specified in the monograph so that the amount of fatty acid increases in proportion to the concentration of the sample solution, when measuring under the conditions described in Procedure. The concentration is normally 1 to 5 fat digestive activity unit/mL.

3.2. Preparation of Substrate Solution

Take 200 to 300 mL of a mixture of emulsifier and olive oil (3:1) in a blender (see Fig. 4.03-2), and emulsify it at 12,000 to 16,000 revolutions per minute for 10 minutes, while cooling the solution to a temperature below 10°C.

Stand this solution in a cool place for 1 hour, and make sure before use that the oil does not separate.

3.3. Preparation of Emulsifier

Dissolve 20 g of polyvinyl alcohol specified in the monograph in 800 mL of water by heating between 75°C and 80°C for 1 hour while stirring. After cooling, filter the solution if necessary, and add water to make exactly 1000 mL.

3.4. Procedure

Pipet 5 mL of the substrate solution and 4 mL of the buffer solution specified in the monograph, transfer them to a conical flask, and shake. After standing the mixture at 37 ± 0.5°C for 10 minutes, add exactly 1 mL of the sample solution, and shake immediately. Stand this solution at 37 ± 0.5°C for exactly 20 minutes, add 10 mL of a mixture of ethanol (95) and acetone (1:1), and shake. Then add exactly 10 mL of 0.05 mol/L sodium hydroxide VS, add 10 mL of a mixture of ethanol (95) and acetone (1:1), and shake. Titrate \( <2.30>\) the excess sodium hydroxide with 0.05 mol/L hydrochloric acid VS (b mL) (indicator: 2 to 3 drops of phenolphthalein TS). Separately, pipet 5 mL of the substrate solution and 4 mL of buffer solution specified in the monograph, transfer them to a conical flask, and shake. After standing it at 37 ± 0.5°C for 10 minutes, add 10 mL of a mixture of ethanol (95) and acetone (1:1), then add exactly 1 mL of the sample solution, and shake. Add exactly 10 mL of 0.05 mol/L sodium hydroxide VS, and titrate \( <2.30>\) in the same manner (\( b \) mL).

**Fat digestive activity (unit/g)**

\[
\text{Fat digestive activity (unit/g)} = \frac{50 \times (a - b) \times \frac{1}{20} \times \frac{1}{M}}{M}
\]

**M:** Amount (g) of sample in 1 mL of sample solution
4.04 Pyrogen Test

Pyrogen Test is a method to test the existence of pyrogens by using rabbits.

1. Test animals

Use healthy mature rabbits, each weighing not less than 1.5 kg, which have not lost body mass when kept on a constant diet for not less than one week. House the rabbits individually in an area free from disturbances likely to excite them. Keep the temperature of the area constant between 20°C and 27°C for at least 48 hours before and throughout the test. Before using a rabbit that has not previously been used for a pyrogen test, condition it 1 to 3 days prior to the test by conducting a sham test omitting the injection. Do not use a rabbit for pyrogen tests more frequently than once every 48 hours, or after it has been given a test sample that was adjudged pyrogen-positive or that contained an antigen present commonly in the test sample to be examined.

2. Apparatus, instruments

(i) Thermometer—Use a rectal thermometer or temperature-measuring apparatus with an accuracy of ±0.1°C or less.

(ii) Syringe and injection needle—Depyrogenate the syringes and needles in a hot-air oven using a validated process, usually by heating at 250°C for not less than 30 minutes. Sterilized syringes with needles are also available provided that they have been validated to assure that they are free of detectable pyrogens and do not interfere with the test.

3. Test procedures

3.1. Quantity of injection

Unless otherwise specified, inject 10 mL of the sample per kg of body mass of each rabbit.

3.2. Procedure

Perform the test in a separate area at an environmental temperature similar to that of the room wherein the animals were housed and free from disturbances likely to excite them. Withhold food from the rabbits for several hours before the first record of the temperature and throughout the testing period. The test animals are usually restrained with loosely fitting neck stocks that allow the rabbits to assume a natural resting posture. Determine the temperature of each rabbit by inserting the thermometer or temperature-measuring probe into the rectum of the test animal to a constant depth within the range of 60 mm to 90 mm. The “control temperature” of each rabbit is the mean of two temperature readings recorded for that rabbit at an interval of 30 min in the 40 min immediately preceding the injection of the sample to be examined. Rabbits showing a temperature variation greater than 0.2°C between the two successive temperature readings or rabbits having an initial temperature higher than 39.8°C are withdrawn from the test.

Warm the test solution to a temperature of 37 ± 2°C before injection, and inject the solution slowly into the marginal vein of the ear of each rabbit over a period not exceeding 10 min. Hypotonic test sample may be made isotonic by the addition of pyrogen-free sodium chloride. Record the temperature of each rabbit during a period of 3 hours after the injection, taking the measurements at intervals of not more than 30 min. The difference between the control temperature and the maximum temperature of each rabbit is taken to be the rise in body temperature. Consider any temperature decreases as zero rise.

4. Interpretation of results

The test is carried out on a group of three rabbits and the result is judged on the basis of the sum of the three temperature rises. Repeat if necessary on further groups of three rabbits to a total of three groups, depending on the results obtained. If the summed response of the first group does not exceed 1.3°C, the sample is judged to be pyrogen-negative. If the summed response exceeds 2.5°C, the sample is judged to be pyrogen-positive. If the summed response exceeds 1.3°C but does not exceed 2.5°C, repeat the test on another group of three rabbits. If the summed response of the first and second group does not exceed 3.0°C, the sample is judged to be pyrogen-negative. If the summed response of the 6 rabbits exceeds 4.2°C, the sample is judged to be pyrogen-positive. If the summed response exceeds 3.0°C but does not exceed 4.2°C, repeat the test on one more group of three rabbits. If the summed response of the 9 rabbits does not exceed 5.0°C, the sample is judged to be pyrogen-negative. If the summed response exceeds 5.0°C, the sample is judged to be pyrogen-positive.

When the test sample is judged to be pyrogen-negative, the sample passes the pyrogen test.

4.05 Microbial Limit Test

This test is harmonized with the European Pharmacopoeia and the U.S. Pharmacopoeia.

This chapter includes microbial enumeration tests and tests for specified micro-organisms. For the test, use a mixture of several portions selected at random from the bulk or from the contents of a sufficient number of containers. If test specimens are diluted with fluid medium, the test should be performed quickly. In performing the test, precautions must be taken to prevent biohazard.

1. Microbiological Examination of Non-sterile Products: Total viable aerobic count

These tests are harmonized with the European Pharmacopoeia and the U.S. Pharmacopoeia. The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi which may grow under aerobic conditions.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes follow the instructions given below, including the number of samples to be taken and interpret the results as stated below.

The methods are not applicable to products containing viable micro-organisms as active ingredients.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeial method has been demonstrated.

1. General Procedures

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the product to be examined. The precautions taken to avoid contamination
must be such that they do not affect any micro-organisms which are to be revealed in the test. If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralized. If inactivators are used for this purpose their efficacy and their absence of toxicity for micro-organisms must be demonstrated.

2. Enumeration Methods

Use the membrane filtration method, or the plate-count methods, as prescribed. The most probable number (MPN) method is generally the least accurate method for microbial counts, however, for certain product groups with very low bioburden, it may be the most appropriate method.

The choice of a method is based on factors such as the nature of the product and the required limit of micro-organisms. The method chosen must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the chosen method must be established.

3. Growth Promotion Test, Suitability of the Counting Method and Negative Controls

The ability of the test to detect micro-organisms in the presence of product to be tested must be established.

Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

3.1. Preparation of test strains

Use standardised stable suspensions of test strains or prepare as stated below.

Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in Table 4.05-I-1.

Use Buffered Sodium Chloride-Peptone Solution (pH 7.0), or Phosphate Buffer (pH 7.2) to make test suspensions; to suspend *Aspergillus brasiliensis* spores, 0.05 per cent of polysorbate 80 may be added to the buffer. Use the suspensions within 2 h or within 24 h if stored at 2 – 8°C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *Aspergillus brasiliensis* or *Bacillus subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2 – 8°C for a validated period of time.

3.2. Negative control

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described under 4. Testing of Products. A failed negative control requires an investigation.

3.3. Growth promotion of the media

Test each batch of ready-prepared medium and each batch of medium, prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of Fluid Soybean-Casein Digest Medium and Soybean-Casein Digest Agar Medium with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 4.05-I-1, using a separate portion/plate of medium for each. Inoculate plates of Sabouraud Glucose Agar Medium with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 4.05-I-1, using a separate plate of medium for each. Incubate in the conditions described in Table 4.05-I-1.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardized inoculum. For a freshly prepared inoculum, growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Liquid media are suitable if clearly visible growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

3.4. Suitability of the counting method in the presence of product

3.4.1. Preparation of the sample

The method for sample preparation depends on the physical characteristics of the product to be tested. If none of the procedures described below can be demonstrated to be satisfactory, an alternative procedure must be developed.

(i) Water-soluble products: Dissolve or dilute (usually a 1 in 10 dilution is prepared) the product to be examined in Buffered Sodium Chloride-Peptone Solution (pH 7.0), Phosphate Buffer (pH 7.2) or Fluid Soybean-Casein Digest Medium. If necessary adjust to pH 6 – 8. Further dilutions, where necessary, are prepared with the same diluent.

(ii) Non-fatty products insoluble in water: Suspend the product to be examined (usually a 1 in 10 dilution is prepared) in Buffered Sodium Chloride-Peptone Solution (pH 7.0), Phosphate Buffer (pH 7.2) or Fluid Soybean-Casein Digest Medium. A surface-active agent such as 1 g/L of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary adjust to pH 6 – 8. Further dilutions, where necessary, are prepared with the same diluent.

(iii) Fatty products: Dissolve in isopropyl myristate, sterilised by filtration or mix the product to be examined with the minimum necessary quantity of sterile polysorbate 80 or another non-inhibitory sterile surface-active reagent, heated if necessary to not more than 40°C, or in exceptional cases to not more than 45°C. Mix carefully and if necessary maintain the temperature in a water-bath. Add sufficient of the pre-warmed chosen diluent to make a 1 in 10 dilution of the original product. Mix carefully whilst maintaining the temperature for the shortest time necessary for the formation of an emulsion. Further serial tenfold dilutions may be prepared using the chosen diluent containing a suitable concentration of sterile polysorbate 80 or another non-inhibitory sterile surface-active reagent.

(iv) Fluids or solids in aerosol form: Aseptically transfer the product into a membrane filter apparatus or a sterile container for further sampling. Use either the total contents or a defined number of metered doses from each of the containers tested.

(v) Transdermal patches: Remove the protective cover sheets ("release liner") of the transdermal patches and place them, adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with sterile porous material, for example sterile gauze, to prevent the patches from sticking together, and transfer the patches to a suitable volume of the chosen diluent containing inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least

3.4.2. Inoculation and dilution

Add to the sample prepared as described above (3.4.1.) and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than 100 CFU. The volume of the suspension of the inoculum should not exceed 1 per cent of the volume of diluted product.

To demonstrate acceptable microbial recovery from the product, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to antimicrobial activity or poor solubility, further appropriate protocols must be developed.

If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the microbial suspension may be added after neutralization, dilution or filtration.

3.4.3. Neutralization/removal of antimicrobial activity

The number of micro-organisms recovered from the prepared sample diluted as described in 3.4.2. and incubated following the procedure described in 3.4.4., is compared to
the number of micro-organisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), then modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example, (1) an increase in the volume of the diluent or culture medium, (2) incorporation of a specific or general neutralizing agents into the diluent, (3) membrane filtration or (4) a combination of the above measures. Neutralizing agents—Neutralizing agents may be used to neutralize the activity of antimicrobial agents (Table 4.05-I-2). They may be added to the chosen diluent or the medium preferably before sterilization. If used, their efficacy and their absence of toxicity for micro-organisms must be demonstrated by carrying out a blank with neutralizing agents, without product.

If no suitable neutralizing method can be found, it can be assumed that the failure to isolate the inoculated organism is attributable to the microbicidal activity of the product. This information serves to indicate that the article is not likely to be contaminated with the given species of the micro-organism. However, it is possible that the product only inhibits some of the micro-organisms specified herein, but does not inhibit others not included amongst the test strains or for which the latter are not representative. Then, perform the test with the highest dilution factor compatible with micro-organisms, or less if large numbers of CFU are expected.

to the membrane filter, filter immediately and rinse the membrane filter with an appropriate volume of diluent.

For the determination of total aerobic microbial count (TAMC), transfer the membrane filter to the surface of Soybean-Casein Digest Agar Medium. For the determination of total combined yeasts/moulds count (TYMC) transfer the membrane to the surface of Sabouraud Glucose Agar Medium. Incubate the plates as indicated in Table 4.05-I-1. Perform the counting.

### 3.4.4.2. Plate-count methods

Perform plate-count methods at least in duplicate for each medium and use the mean count of the result.

(i) Pour-plate method: For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under 3.4.1. to 3.4.3. and 15 – 20 mL of Soybean-Casein Digest Agar Medium or Sabouraud Glucose Agar Medium, both media being at not more than 45°C. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the micro-organisms listed in Table 4.05-I-1, at least 2 Petri dishes are used.

Incubate the plates as indicated in Table 4.05-I-1. Take the arithmetic mean of the counts per medium and calculate the number of CFU in the original inoculum.

(ii) Surface-spread method: For Petri dishes 9 cm in diameter, add 15 – 20 mL of Soybean-Casein Digest Agar Medium or Sabouraud Glucose Agar Medium at about 45°C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or in an incubator. For each of the micro-organisms listed in Table 4.05-I-1, at least 2 Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample prepared as described under 3.4.1. to 3.4.3. over the surface of the medium. Incubate and count as prescribed under 3.4.4.2. (i).

### 3.4.4.3. Most-probable-number (MPN) method

The precision and accuracy of the MPN method is less than that of the membrane filtration method or the plate-count method. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of TAMC in situations where no other method is available. If the use of the method is justified, proceed as follows.

</tbody>
</table>

Prepare a series of at least 3 serial tenfold dilutions of the product as described under 3.4.1. to 3.4.3. From each level of dilution, 3 aliquots of 1 g or 1 mL are used to inoculate 3 tubes with 9 – 10 mL of Fluid Soybean-Casein Digest Medium. If necessary a surface-active agent such as polysorbate 80, or an inactivator of antimicrobial agents may be added.
to the medium. Thus, if 3 levels of dilution are prepared 9 tubes are inoculated.

Incubate all tubes at 30 – 35°C for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth, or Soybean-Casein Digest Agar Medium, for 1 – 2 days at the same temperature and use these results. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 4.05-1.3.

3.5. Results and interpretation

When verifying the suitability of the membrane filtration method or the plate-count method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in 3.4.2. in the absence of the product must be obtained. When verifying the suitability of the MPN method the calculated value from the inoculum must be within 95 per cent confidence limits of the results obtained with the control.

If the above criteria cannot be met for one or more of the organisms tested with any of the described methods, the method and test conditions that come closest to the criteria are used to test the product.

4. Testing of Products

4.1. Amount used for the test

Unless otherwise prescribed, use 10 g or 10 mL of the product to be examined taken with the precautions referred to above. For fluids or solids in aerosol form, sample 10 containers. For transdermal patches, sample 10 patches.

The amount to be tested may be reduced for Active Pharmaceutical Ingredients that will be formulated in the follow-

4.2. Examination of the product

4.2.1. Membrane filtration method

Use a filtration apparatus designed to allow the transfer of the filter to the medium. Prepare the sample using a method that has been shown suitable as described in section 3 and transfer the appropriate amount to each of 2 membrane filters and filter immediately. Wash each filter following the procedure shown to be suitable.

For the determination of TAMC, transfer one of the membrane filters to the surface of Sabouraud Glucose Agar Medium. For the determination of TYMC, transfer the other membrane to the surface of Sabouraud Glucose Agar Medium. Incubate the plate of Soybean-Casein Digest Agar Medium at 30 – 35°C for 3 – 5 days and the plate of Sabouraud Glucose Agar Medium at 20 – 25°C for 5 – 7 days. Calculate the number of CFU per gram or per millilitre of product.

When examining transdermal patches, filter 10 per cent of the volume of the preparation described under 3.4.1. separately through each of 2 sterile filter membranes. Transfer one membrane to Soybean-Casein Digest Agar Medium for TAMC and the other membrane to Sabouraud Glucose Agar Medium for TYMC.

4.2.2. Plate-count methods

(i) Pour-plate method: Prepare the sample using a method that has been shown to be suitable as described in section 3. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates of Soybean-Casein Digest Agar Medium at 30 – 35°C for 3 – 5 days and the plates of Sabouraud Glucose Agar Medium at 20 – 25°C for 5 – 7 days. Select the plates corresponding to a given dilution and showing the highest number of colonies less than 250 for TAMC and 50 for TYMC. Take the arithmetic mean per culture medium of the counts and calculate the number of CFU per gram or per millilitre of product.

(ii) Surface-spread method: Prepare the sample using a method that has been shown to be suitable as described in section 3. Prepare at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of CFU proceed as described for the pour-plate method.

4.2.3. Most-probable-number method

Prepare and dilute the sample using a method that has been shown to be suitable as described in section 1.3. Incubate all tubes for 3 – 5 days at 30 – 35°C. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 4.05-1.3.

4.3. Interpretation of the results

The total aerobic microbial count (TAMC) is considered to be equal to the number of CFU found using Soybean-Casein Digest Agar Medium; if colonies of fungi are detected on this medium, they are counted as part of TAMC. The total combined yeasts/mould count (TYMC) is considered to be equal to the number of CFU found using Sabouraud Glucose Agar Medium; if colonies of bacteria are detected on this medium, they are counted as part of TYMC. When the TYMC is expected to exceed the acceptance criterion due to the bacterial growth, Sabouraud Glucose Agar Medium containing antibiotics may be used. If the count is carried out by the MPN method the calculated value is the TAMC.

When an acceptance criterion for microbiological quality is prescribed it is interpreted as follows:

- $10^3$ CFU: maximum acceptable count = 20,
- $10^4$ CFU: maximum acceptable count = 200,
- $10^5$ CFU: maximum acceptable count = 2000, and so forth.

The recommended solutions and media are described in Tests for specified micro-organisms.

II. Microbiological Examination of Non-sterile Products: Tests for Specified Micro-organisms

These tests are harmonized with the European Phar-
Macropoënia and the U.S. Pharmacopoeia.

The tests described hereafter will allow determination of the absence of, or limited occurrence of specified microorganisms which may be detected under the conditions described.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes follow the instructions given below, including the number of samples to be taken and interpret the results as stated below.

Alternative microbiological procedures, including automated methods may be used, provided that their equivalence to the Pharmacopoeial method has been demonstrated.

1. General Procedures

The preparation of samples is carried out as described in I. Total viable aerobic count.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralized as described in I. Total viable aerobic count.

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated as described in I. Total viable aerobic count.

2. Growth Promoting and Inhibitory Properties of the Media, Suitability of the Test and Negative Controls

The ability of the test to detect micro-organisms in the presence of the product to be tested must be established. Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

2.1. Preparation of test strains

Use standardised stable suspensions of test strains or prepare as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages previously obtained with a previously tested and approved batch.

2.1.1. Aerobic micro-organisms

Grow each of the bacterial test strains separately in containers containing Fluid Soybean-Casein Digest Medium or on Soybean-Casein Digest Agar Medium at 30 – 35°C for 18 – 24 hours. Grow the test strain for Candida albicans separately on Sabouraud Glucose Agar Medium or in Fluid Sabouraud Glucose Medium at 20 – 25°C for 2–3 days.

Staphylococcus aureus such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276,

Pseudomonas aeruginosa such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275,

Escherichia coli such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972,

Salmonella enterica subsp. enterica serovar Typhimurium such as ATCC 14028

or, as an alternative, Salmonella enterica subsp. enterica serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39, Candida albicans such as ATCC 10231, NCPF 3179, IP 48.72 or NBRC 1594.

Use Buffered Sodium Chloride-Peptone Solution (pH 7.0) or Phosphate Buffer (pH 7.2) to make test suspensions. Use the suspensions within 2 hours or within 24 hours if stored at 2 – 8°C.

2.1.2. Clostridia

Use Clostridium sporogenes such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.3). Grow the clostridial test strain under anaerobic conditions in Reinforced Clostridial Medium at 30 – 35°C for 24 – 48 hours. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of Cl. sporogenes, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2 – 8°C for a validated period.

2.2. Negative control

To verify testing conditions a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described under 3. A failed negative control required an investigation.

2.3. Growth promotion and inhibitory properties of the media

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients.

Verify suitable properties of relevant media as described in Table 4.05-II-1.

(i) Test for growth promoting properties, liquid media: inoculate a portion of the appropriate medium with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

(ii) Test for growth promoting properties, solid media: perform surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

(iii) Test for inhibitory properties, liquid or solid media: inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. Growth of the micro-organism occurs.

(iv) Test for indicative properties: perform surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

2.4. Suitability of the test method

For each product to be tested perform sample preparation as described in the relevant paragraph in section 3. Add each test strain at the time of mixing, in the prescribed growth medium. Inoculate the test strains individually. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation.

Perform the test as described in the relevant paragraph in section 3 using the shortest incubation period prescribed.

</table>

The specified micro-organisms must be detected with the indication reactions as described in section 3.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see I. of Total viable aerobic count).

If for a given product the antimicrobial activity with respect to a micro-organism for which testing is prescribed cannot be neutralised, then it is to be assumed that the inhibited micro-organism will not be present in the product.
3. Testing of Products

3.1. Bile-tolerant gram-negative bacteria

3.1.1. Sample preparation and pre-incubation
Preparation a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in I. Total viable aerobic count, but using Fluid Soybean-Casein Digest Medium as the chosen diluent, mix and incubate at 20 – 25°C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 hours but not more than 5 hours).

3.1.2. Test for absence
Unless otherwise prescribed use the volume corresponding to 1 g of the product, as prepared in 3.1.1. to inoculate Fluid Enterobacteria Enrichment Broth Mossel Medium. Incubate at 30 – 35°C for 24 – 48 hours. Subculture on plates of VRB (Violet/Red/Bile) Agar with glucose. Incubate at 30 – 35°C for 18 – 24 hours.

The product complies with the test if there is no growth of colonies.

3.1.3. Quantitative test

3.1.3.1. Selection and subculture
Inoculate suitable quantities of Fluid Enterobacteria Enrichment Broth Mossel Medium with the preparation as described under 3.1.1. and/or dilutions of it containing respectively 0.1 g, 0.01 g and 0.001 g (or 0.1 mL, 0.01 mL and 0.001 mL) of the product to be examined. Incubate at 30 – 35°C for 24 – 48 hours. Subculture each of the cultures on a plate of VRB (Violet/Red/Bile) Agar with glucose. Incubate at 30 – 35°C for 18 – 24 hours.

3.1.3.2. Interpretation
Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from Table 4.05-II-2 the probable number of bacteria.

3.2. Escherichia coli

3.2.1. Sample preparation and pre-incubation
Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in I. Microbial Enumeration Tests and use 10 mL of the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 2.4.) of Fluid Soybean-Casein Digest Medium, mix and incubate at 30 – 35°C for 18 – 24 hours.

3.2.2. Selection and subculture
Shake the container, transfer 1 mL of Fluid Soybean-Casein Digest Medium to 100 mL of Fluid MacConkey Broth Medium and incubate at 42 – 44°C for 24 – 48 hours. Subculture on a plate of MacConkey Agar Medium at 30 – 35°C for 18 – 72 hours.

3.2.3. Interpretation
Growth of colonies indicates the possible presence of E. coli. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

3.3. Salmonella

3.3.1. Sample preparation and pre-incubation
Prepare the product to be examined as described in I. Total viable aerobic count and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under 2.4.) of Fluid Soybean-Casein Digest Medium, mix and incubate at 30 – 35°C for 18 – 24 hours.

3.3.2. Selection and subculture
Transfer 0.1 mL of Fluid Soybean-Casein Digest Medium to 10 mL of Fluid Rappaport Vassiliadis Salmonella Enrichment Broth Medium and incubate at 30 – 35°C for 18 – 24 hours. Subculture on plates of XLD (Xylose-Lysine-Desoxycholate) Agar Medium. Incubate at 30 – 35°C for 18 – 48 hours.

3.3.3. Interpretation
The possible presence of Salmonella is indicated by the growth of well-developed, red colonies, with or without black centres. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

3.4. Pseudomonas aeruginosa

3.4.1. Sample preparation and pre-incubation
Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in I. Total viable aerobic count and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 2.4.) of Fluid Soybean-Casein Digest Medium and mix. When testing transdermal patches, filter the volume of sample corresponding to 1 patch of the preparation described in I. Total viable aerobic count (3.4.1.) through a sterile filter membrane and place in 100 mL of Fluid Soybean-Casein Digest Medium. Incubate at 30 – 35°C for 18 – 24 hours.

3.4.2. Selection and subculture
Subculture on a plate of Cetrimide Agar Medium and incubate at 30 – 35°C for 18 – 72 hours.

3.4.3. Interpretation
Growth of colonies indicates the possible presence of P. aeruginosa. This is confirmed by identification tests.

The product complies with the test if colonies are not present or if the confirmatory identification tests are negative.

3.5.  *Staphylococcus aureus*

3.5.1. Sample preparation and pre-incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in I. Microbial Enumeration Tests and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 2.4.) of Fluid Soybean-Casein Digest Medium and homogenise. When testing transdermal patches, filter the volume of sample corresponding to 1 patch of the preparation described in I. Total viable aerobic count (3.4.1.) through a sterile filter membrane and place in 100 mL of Fluid Soybean-Casein Digest Medium. Incubate at 30 – 35°C for 18 – 24 hours.

3.5.2. Selection and subculture

Subculture on a plate of Mannitol Salt Agar Medium and incubate at 30 – 35°C for 18 – 72 hours.

3.5.3. Interpretation

The possible presence of *S. aureus* is indicated by the growth of yellow/white colonies surrounded by a yellow zone. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

3.6.  *Clostridia*

3.6.1. Sample preparation and heat treatment

Prepare a sample using a 1 in 10 dilution (with a minimum total volume of 20 mL) of not less than 2 g or 2 mL of the product to be examined as described in I. Total viable aerobic count.

Divide the sample into two portions of at least 10 mL. Heat 1 portion at 80°C for 10 min and cool rapidly. Do not heat the other portion.

3.6.2. Selection and subculture

Use 10 mL or the quantity corresponding to 1 g or 1 mL of the product to be examined of both portions to inoculate suitable amounts (determined as described under 2.4.) of Reinforced Clostridial Medium. Incubate under anaerobic conditions at 30 – 35°C for 48 hours. After incubation, make subcultures from each tube on Columbia Agar Medium and incubate under anaerobic conditions at 30 – 35°C for 48 – 72 hours.

3.6.3. Interpretation

The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction indicates the presence of *Clostridia*.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

3.7.  *Candida albicans*

3.7.1. Sample preparation and pre-incubation

Prepare the product to be examined as described in I. Microbial Enumeration Tests and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL to inoculate 100 mL of Fluid Sabouraud Glucose Medium and mix. Incubate at 30 – 35°C for 3-5 days.

3.7.2. Selection and subculture

Subculture on a plate of Sabouraud Glucose Agar Medium and incubate at 30 – 35°C for 24 – 48 hours.

3.7.3. Interpretation

Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The product complies with the test if such colonies are not present or if the confirmatory identification tests are negative.

The following section is given for information.

4.  Recommended Solutions and Culture Media

The following solutions and culture media have been found satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopoeia. Other media may be used provided that their suitability can be demonstrated.

(i)  Phosphate Buffer (pH 7.2)

Prepare a mixture of water and stock buffer solution (800:1 V/V) and sterilize.

Stock buffer solution. Transfer 34 g of potassium dihydrogen phosphate to a 1000 mL volumetric flask, dissolve in 500 mL of purified water, adjust to pH 7.1 to 7.3 with sodium hydroxide, add purified water to volume and mix. Dispense in containers and sterilize. Store at a temperature of 2 – 8°C.

(ii) Buffered Sodium Chloride-Peptone Solution (pH 7.0)

Potassium dihydrogen phosphate 3.6 g

Disodium hydrogen phosphate dihydrate 7.2 g

(equivalent to 0.067 mol phosphate)

Sodium chloride 4.3 g

Peptone (meat or casein) 1.0 g

Water 1000 mL

Sterilize in an autoclave using a validated cycle.

(iii) Fluid Soybean-Casein Digest Medium

Casein peptone 17.0 g

Soybean peptone 3.0 g

Sodium chloride 5.0 g

Dipotassium hydrogen phosphate 2.5 g

Glucose 2.5 g

Water 1000 mL

Adjust the pH so that after sterilization it is 7.1 – 7.5 at 25°C. Sterilize in an autoclave using a validated cycle.

(iv) Soybean-Casein Digest Agar Medium

Casein peptone 15.0 g

Soybean peptone 5.0 g

Sodium chloride 5.0 g

Agar 15.0 g

Water 1000 mL

Adjust the pH so that after sterilization it is 7.1 – 7.5 at 25°C. Sterilize in an autoclave using a validated cycle.

(v) Sabouraud Glucose Agar Medium

Glucose 40.0 g

Peptones (animal tissue and casein 1:1) 10.0 g

Agar 15.0 g

Water 1000 mL

Adjust the pH so that after sterilization it is 5.4 – 5.8 at 25°C. Sterilize in an autoclave using a validated cycle.

(vi) Potato Dextrose Agar Medium

Infusion from potatoes 200 g

Glucose 20.0 g

Agar 15.0 g

Water 1000 mL

Adjust the pH so that after sterilization it is 5.4 – 5.8 at 25°C. Sterilize in an autoclave using a validated cycle.
### Fluid Sabouraud Glucose Medium
- **Glucose**: 20.0 g
- **Peptones (animal tissue and casein 1:1)**: 10.0 g
- **Water**: 1000 mL

Adjust the pH so that after sterilization it is 5.4 – 5.8 at 25°C. Sterilize in an autoclave using a validated cycle.

### Fluid Enterobacteria Enrichment Broth Mossel Medium
- **Gelatin peptone**: 10.0 g
- **Glucose**: 5.0 g
- **Bile salts**: 20.0 g
- **Potassium dihydrogen phosphate**: 2.0 g
- **Disodium hydrogen phosphate dihydrate**: 8.0 g
- **Brilliant green**: 15 mg
- **Water**: 1000 mL

Adjust the pH so that after heating it is 7.0 – 7.4 at 25°C. Heat at 100°C for 30 min and cool immediately.

### VRB (Violet/Red/Bile) Agar with glucose
- **Yeast extract**: 3.0 g
- **Gelatin peptone**: 7.0 g
- **Bile salts**: 1.5 g
- **Sodium chloride**: 5.0 g
- **Neutral red**: 30 mg
- **Crystal violet**: 2 mg
- **Water**: 1000 mL

Adjust the pH so that after heating it is 7.2 – 7.6 at 25°C. Heat to boiling; do not heat in an autoclave.

### Fluid MacConkey Broth Medium
- **Gelatin peptone**: 20.0 g
- **Lactose monohydrate**: 10.0 g
- **Dehydrated ox bile**: 5.0 g
- **Bromocresol purple**: 10 mg
- **Water**: 1000 mL

Adjust the pH so that after sterilization it is 7.1 – 7.5 at 25°C. Sterilize in an autoclave using a validated cycle.

### MacConkey Agar Medium
- **Gelatin peptone**: 17.0 g
- **Peptones (meat and casein)**: 3.0 g
- **Lactose monohydrate**: 10.0 g
- **Sodium chloride**: 5.0 g
- **Bile salts**: 1.5 g
- **Agar**: 13.5 g
- **Neutral red**: 30 mg
- **Crystal violet**: 1 mg
- **Water**: 1000 mL

Adjust the pH so that after sterilization it is 7.1 – 7.5 at 25°C. Boil for 1 min with constant shaking then sterilize in an autoclave using a validated cycle.

### Fluid Rappaport Vassiliadis Salmonella Enrichment Medium
- **Soya peptone**: 4.5 g
- **Magnesium chloride hexahydrate**: 29.0 g
- **Sodium chloride**: 8.0 g
- **Potassium dihydrogen phosphate**: 0.4 g
- **Malachite green**: 36 mg
- **Water**: 1000 mL

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilization it is about 6.6 – 7.0 at 25°C. Sterilize in an autoclave using a validated cycle.
4.06 Sterility Test

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopoeia. The parts of the text that are not harmonized are marked with symbols (ⅩⅦ). The test is applied to active pharmaceutical ingredients, preparations or articles which, according to the Pharmacopoeia, are required to be sterile. However, a satisfactory result only indicates that no contaminating micro-organisms has been found in the sample examined in the conditions of the test.

1. Precautions against microbial contamination

The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any micro-organisms which are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls.

2. Culture media and incubation temperatures

Media for the test may be prepared as described below, or equivalent commercial media may be used provided that they comply with the growth promotion test. The following culture media have been found to be suitable for the test for sterility. Fluid thioglycollate medium is primarily intended for the culture of anaerobic bacteria; however, it will also detect aerobic bacteria. Soybean casein digest medium is suitable for the culture of both fungi and aerobic bacteria.

(i) Fluid thioglycollate medium

Mix the l-cystine, agar, sodium chloride, glucose, watersoluble yeast extract and pancreatic digest of casein with water, and heat until solution is effectuated. Dissolve the sodium thioglycollate or thioglycolic acid in the solution and, if necessary, add sodium hydroxide TS so that, after sterilization, the solution will have a pH of 7.1 ± 0.2. If filtration is necessary, heat the solution again without boiling and filter while hot through moistened filter paper. Add the resazurin sodium solution (1 in 1000), mix and place the medium in suitable vessels which provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a color change indicative of oxygen uptake at the end of the incubation period. Sterilize using a validated process. If the medium is stored, store at a temperature between 2°C and 25°C in a sterile, tight container. If more than the upper one-third of the medium has acquired a pink color, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink color disappears and cooling quickly, taking care to prevent the introduction of non-sterile air into the container. Do not use the medium for a longer storage period than has been validated.

Fluid thioglycollate medium is to be incubated at 30–35°C. For products containing a mercurial preservative that cannot be tested by the membrane-filtration method, fluid thioglycollate medium incubated at 20–25°C may be used instead of soya-bean casein digest medium provided that it has been validated as described in growth promotion test.

Where prescribed or justified and authorized, the following alternative thioglycollate medium might be used. Prepare a mixture having the same composition as that of the fluid thioglycollate medium, but omitting the agar and the resazurin sodium solution (1 in 1000), sterilize as directed above. The pH after sterilization is 7.1 ± 0.2. Heat in a water bath prior to use and incubate at 30–35°C under anaerobic conditions.

(ii) Soybean casein digest medium

Mix the l-cystine, agar, sodium chloride, glucose, watersoluble yeast extract and pancreatic digest of casein with water, and heat until solution is effectuated. Dissolve the sodium thioglycollate or thioglycolic acid in the solution and, if necessary, add sodium hydroxide TS so that, after sterilization, the solution will have a pH of 7.3 ± 0.2. If filtration is necessary, heat the solution again without boiling and filter while hot through moistened filter paper. Add the resazurin sodium solution (1 in 1000), mix and place the medium in suitable vessels which provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a color change indicative of oxygen uptake at the end of the incubation period. Sterilize using a validated process. If the medium is stored, store at a temperature between 2°C and 25°C in a sterile, tight container. If more than the upper one-third of the medium has acquired a pink color, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink color disappears and cooling quickly, taking care to prevent the introduction of non-sterile air into the container. Do not use the medium for a longer storage period than has been validated.

Fluid thioglycollate medium is to be incubated at 30–35°C. For products containing a mercurial preservative that cannot be tested by the membrane-filtration method, fluid thioglycollate medium incubated at 20–25°C may be used instead of soya-bean casein digest medium provided that it has been validated as described in growth promotion test.

Where prescribed or justified and authorized, the following alternative thioglycollate medium might be used. Prepare a mixture having the same composition as that of the fluid thioglycollate medium, but omitting the agar and the resazurin sodium solution (1 in 1000), sterilize as directed above. The pH after sterilization is 7.1 ± 0.2. Heat in a water bath prior to use and incubate at 30–35°C under anaerobic conditions.

3. Suitability of the culture medium

The media used comply with the following tests, carried out before or in parallel with the test on the product to be examined.

3.1 Sterility

Incubate portions of the media for 14 days. No growth of micro-organisms occurs.
Table 4.06-1. Strains of the test micro-organisms suitable for use in the Growth Promotion Test and the Method suitability Test

3.2. Growth promotion test of aerobes, anaerobes and fungi

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients. Suitable strains of micro-organisms are indicated in Table 4.06-1.

Inoculate portions of fluid thioglycollate medium with a small number (not more than 100 CFU) of the following microorganisms, using a separate portion of medium for each of the following species of micro-organism:

- *Aspergillus brasiliensis*, *Staphylococcus aureus*, *Bacillus subtilis*, *Clostridium sporogenes*, *Pseudomonas aeruginosa*, *Candida albicans*.

Inoculate portions of soya-bean casein digest medium with a small number (not more than 100 CFU) of the following microorganisms, using a separate portion of medium for each of the following species of micro-organism:

- *Aspergillus brasiliensis*, *Staphylococcus aureus*.

Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi.

Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than five passages removed from the original master seed-lot.

The media are suitable if a clearly visible growth of the micro-organisms occurs.

4. Method suitability test

Carry out a test as described below under 5. Test for sterility of the product to be examined using exactly the same methods except for the following modifications.

(i) Membrane filtration: After transferring the content of the container or containers to be tested to the membrane add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the final portion of sterile diluent used to rinse the filter.

(ii) Direct inoculation: After transferring the contents of the container or containers to be tested to the culture medium add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the medium.

In both cases use the same micro-organisms as those described above under 3.2. Growth promotion test of aerobes, anaerobes and fungi. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of micro-organisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity and repeat the method suitability test.

This method suitability is performed:

a) when the test for sterility has to be carried out on a new product;

b) whenever there is a change in the experimental conditions of the test.

The method suitability may be performed simultaneously with the Test for sterility of the product to be examined.

5. Test for sterility of the product to be examined

The test may be carried out using the technique of membrane filtration or by direct inoculation of the culture media with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits, that is, for filterable aqueous preparations, for alcoholic or oily preparations and for preparations miscible with or soluble in aqueous or oily solvents provided these solvents do not have an antimicrobial effect in the conditions of the test.

5.1. Membrane filtration

Use membrane filters having a nominal pore size not greater than 0.45 μm whose effectiveness to retain microorganisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily and weakly alcoholic solutions and cellulose acetate filters, for example, for strongly alcoholic solutions. Specially adapted filters may be needed for certain products, e.g. for antibiotics.

The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilized by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions; it permits the aseptic removal of the membrane for transfer to the medium or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

(i) Aqueous solutions: If appropriate, transfer a small quantity of a suitable, sterile diluent such as a 1 g/L neutral solution of meat or casein peptone pH 7.1 ± 0.2 onto the membrane in the apparatus and filter. The diluent may contain suitable neutralizing substances and/or appropriate inactivating substances for example in the case of antibiotics.

Transfer the contents of the container or containers to be
tested to the membrane or membranes, if necessary after diluting to the volume used in the method suitability test with the chosen sterile diluent but in any case using not less than the quantities of the product to be examined prescribed in Table 4.06-2. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than three times by filtering through it each time the volume of the chosen sterile diluent used in the method suitability test. Do not exceed a washing cycle of 5 times 100 mL per filter, even if during method suitability it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into two equal parts and transfer one half to each of two suitable media. Use the same volume of each medium as in the method suitability test. Alternatively, transfer the membrane onto the membrane in the apparatus. Incubate the media for not less than 14 days. If no evidence of microbial growth is found, the product complies with the test for sterility. If evidence of microbial growth is found examine the media for macroscopic evidence of microbial growth. If the material being tested renders the detection of anaerobic micro-organisms keep shaking or mixing to a minimum in order to maintain anaerobic conditions. Incubate the media for not less than 14 days.

(ii) Soluble solids: Use for each medium not less than the quantity prescribed in Table 4.06-2 of the product dissolved in a suitable solvent such as the solvent provided with the preparation, water for injection, saline or a 1 g/L neutral solution of meat or casein peptone and proceed with the test as described above for aqueous solutions using a membrane appropriate to the chosen solvent.

(iii) Oils and oily solutions: Use for each medium not less than the quantity of the product prescribed in Table 4.06-2. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as isopropyl myristate shown not to have antimicrobial activity in the conditions of the test. Allow the oil to penetrate the membrane by its own weight then filter, applying the pressure or suction gradually. Wash the membrane at least three times by filtering through it each time about 100 mL of a suitable sterile solution such as 1 g/L neutral meat or casein peptone containing a suitable emulsifying agent at a concentration shown to be appropriate in the method suitability of the test, for example polysorbate 80 at a concentration of 10 g/L. Transfer the membrane or membranes to the culture medium or media or vice versa as described above for aqueous solutions, and incubate at the same temperatures and for the same times.

(iv) Ointments and creams: Use for each medium not less than the quantities of the product prescribed in Table 4.06-2. Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1 per cent in isopropyl myristate as described above, by heating, if necessary, to not more than 40°C. In exceptional cases it may be necessary to heat to not more than 44°C. Filter as rapidly as possible and proceed as described above for oils and oily solutions.

5.2. Direct inoculation of the culture medium
Transfer the quantity of the preparation to be examined prescribed in Table 4.06-2 directly into the culture medium so that the volume of the product is not more than 10 per cent of the volume of the medium, unless otherwise prescribed. If the product to be examined has antimicrobial activity, carry out the test after neutralizing this with a suitable neutralizing substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product it may be preferable to use a concentrated culture medium prepared in such a way that it takes account of the subsequent dilution. Where appropriate the concentrated medium may be added directly to the product in its container.

(i) Oily liquids: Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the method suitability of the test, for example polysorbate 80 at a concentration of 10 g/L.

(ii) Ointments and creams: Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as a 1 g/L neutral solution of meat or casein peptone. Transfer the diluted product to a medium not containing an emulsifying agent. Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However when fluid thioglycollate medium is used for the detection of anaerobic micro-organisms keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

6. Observation and interpretation of results
At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 mL) of the medium to fresh vessels of the same medium and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found the product to be exa-

* If the batch size is not known, use the maximum number of items prescribed

** If the contents of one container are enough to inoculate the two media, this column gives the number of containers needed for both the media together.

examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

(i) the data of the microbiological monitoring of the sterility testing facility show a fault;
(ii) a review of the testing procedure used during the test in question reveals a fault;
(iii) microbial growth is found in the negative controls;
(iv) after determination of the identity of the microorganisms isolated from the test, the growth of this species or these species may be ascribed unequivocally to faults with respect to the material and/or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid it is repeated with the same number of units as in the original test. If no evidence of microbial growth is found in the repeat test the product examined complies with the test for sterility. If microbial growth is found in the repeat test the product examined does not comply with the test for sterility.

7. Application of the test to parenteral preparations, ophthalmic and other non-injectable preparations required to comply with the test for sterility

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in Table 4.06-2, diluting where necessary to about 100 mL with a suitable sterile solution, such as 1 g/L neutral meat or casein peptone.

When using the technique of direct inoculation of media, use the quantities shown in Table 4.06-2, unless otherwise justified and authorized. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of two or more containers are used to inoculate the different media.

8. Minimum number of items to be tested

The minimum number of items to be tested in relation to the size of the batch is given in Table 4.06-3.

5. Tests for Crude Drugs

5.01 Crude Drugs Test

Crude Drugs Test is applied to the crude drugs mentioned in the General Rules for Crude Drugs.

1. Sampling

Unless otherwise specified, sample should be taken by the following methods. If necessary, preserve the samples in tight containers.

(i) When crude drugs to be sampled are small-sized, cut or powdered, 50 to 250 g of sample should be taken after mixing thoroughly.
(ii) When crude drugs to be sampled are large-sized, 250 to 500 g of sample should be taken after mixing thoroughly.
(iii) When the mass of each single piece of the crude drugs is not less than 100 g, not less than 5 pieces should be taken for a sample, or not less than 500 g of the sample should be taken after cutting to a suitable size and mixing thoroughly.

2. Preparation of the test sample for analysis

Preparations are to be made by mixing the sample well. Powdered drugs should be used as they are, and in the case of unpowdered drugs, unless otherwise specified, grind the sample into powder. If the sample cannot be ground into powder, reduce it as finely as possible, spread it out in a thin layer, and withdraw a typical portion for analysis. If necessary, preserve the test sample in a tight container.

3. Micropic examination

3.1. Apparatus

Use an optical microscope with objectives of 10 and 40 magnifications, and an ocular of 10 magnifications.

3.2. Preparation for microscopic examination

(i) Section: To a section on a slide glass add 1 to 2 drops
of a mounting agent, and put a cover glass on it, taking precaution against inclusion of bubbles. Usually use a section 10 to 20 μm in thickness.

(ii) Powder: Place about 1 mg of powdered sample on a slide glass, add 1 to 2 drops of a swelling agent, stir well with a small rod preventing inclusion of bubbles, and allow to stand for a while to swell the sample. Add 1 drop of the mounting agent, and put a cover glass on it so that the tissue sections spread evenly without overlapping each other, taking precaution against inclusion of bubbles. In the case where the tissue sections are opaque, place about 1 mg of powdered sample on a slide glass, add 1 to 2 drops of chloral hydrate TS, heat to make the tissues clear while stirring with a small glass rod to prevent boiling. After cooling, add 1 drop of mounting agent, and put a cover glass on it in the same manner as above.

Unless otherwise specified, use a mixture of glycerin and water (1:1) or a mixture of water, ethanol (95) and glycerin (1:1:1) as the mounting agent and swelling agent.

3.3. Observation of components in the Description

In each monograph, description is usually given of the outer portion and the inner portion of a section in this order, followed by a specification of cell contents. Observation should be made in the same order. In the case of a powdered sample, description is given of a characteristic component or a matter present in large amount, rarely existing matter, and cell contents in this order. Observation should be made in the same order.

4. Purity

4.1. Foreign matter

Unless otherwise specified, weigh 25 to 500 g of the sample, spread out in a thin layer, and separate the foreign matter by inspecting with the naked eye or with the use of a magnifying glass of 10 magnifications. Weigh, and determine the percentage of foreign matter.

4.2. Total BHC’s and total DDT’s

Sodium chloride, anhydrous sodium sulfate and synthetic magnesium silicate for column chromatography used in this procedure are used after drying by heating at about 130°C for more than 12 hours and cooling in a desiccator (silica gel). Chromatographic column is prepared as follows: Place 20 g of synthetic magnesium silicate for column chromatography in a 200-mL flask, add 50 mL of hexane for Purity of crude drug, shake vigorously, and immediately pour the mixture into a chromatographic tube about 2 cm in inside diameter and about 30 cm in length. Drip until the depth of hexane layer at the upper part is about 5 cm, introduce 8 g of anhydrous sodium sulfate from the top, and further drip until a small quantity of hexane is left at the upper part.

Weigh accurately about 5 g of pulverized sample, place in a glass-stoppered centrifuge tube, add 30 mL of a mixture of acetone for Purity of crude drug and water (5:2), stopper tightly, shake for 15 minutes, centrifuge, and separate the supernatant liquid. Repeat the same procedure twice with the residue using two 30-mL portions of the mixture of acetone for Purity of crude drug and water (5:2). Combine all the supernatant liquids, and concentrate under reduced pressure at a temperature not higher than 40°C until the order of acetone is faint. Transfer the concentrated solution to a separator containing 50 mL of sodium chloride TS, and shake twice with two 50-mL portions of hexane for Purity of crude drug for 5 minutes each. Combine the hexane layers, transfer to a separator containing 50 mL of sodium chloride TS, and shake for 5 minutes. Take the hexane layer, dry with 30 g of anhydrous sodium sulfate, and filter. Wash the residue on the filter paper with 20 mL of hexane for Purity of crude drug. Combine the filtrate and the washings, and concentrate under reduced pressure at a temperature not higher than 40°C to about 5 mL. Transfer this solution to the chromatographic column and allow to pass with 300 mL of a mixture of hexane for Purity of crude drug and diethyl ether for Purity of crude drug (17:3) at a rate of not more than 5 mL per minute. After concentrating the eluate under reduced pressure at a temperature not higher than 40°C, add hexane for Purity of crude drug to make exactly 5 mL. Transfer this solution to a glass-stoppered test tube, add 1 mL of sulfuric acid, and shake carefully. Take 4 mL of the upper layer, transfer to a separate glass-stoppered test tube, add 2 mL of water, and shake gently. Usually take 3 mL of the upper layer so obtained, transfer to a glass-stoppered centrifuge tube, dry with 1 g of anhydrous sodium sulfate, centrifuge, and use the supernatant liquid as the sample solution. Separately, weigh accurately about 10 mg each of α-BHC, β-BHC, γ-BHC, δ-BHC, o,p′-DDT, p,p′-DDT, p,p′-DDE and p,p′-DDE, dissolve in 5 mL of acetone for Purity of crude drug, and add hexane for Purity of crude drug to make exactly 100 mL. Pipet 10 mL of this solution, and add hexane for Purity of crude drug to make exactly 100 mL. Pipet 1 mL of this solution, add hexane for Purity of crude drug to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 1 μL each of the sample solution and the standard solution as directed under Gas Chromatography. Calculate the content of each of α-BHC, β-BHC, γ-BHC, δ-BHC, o,p′-DDT, p,p′-DDT, p,p′-DDE and p,p′-DDE by means of the following equations.

Content (ppm) of α-BHC

\[
\text{Content (ppm) of} \ \alpha-BHC = \frac{\text{amount (g) of } \alpha-BHC}{M} \times \frac{A_{\text{TA}}}{A_{\text{SA}}} \times 50
\]

Content (ppm) of β-BHC

\[
\text{Content (ppm) of} \ \beta-BHC = \frac{\text{amount (g) of } \beta-BHC}{M} \times \frac{A_{\text{TB}}}{A_{\text{SB}}} \times 50
\]

Content (ppm) of γ-BHC

\[
\text{Content (ppm) of} \ \gamma-BHC = \frac{\text{amount (g) of } \gamma-BHC}{M} \times \frac{A_{\text{TC}}}{A_{\text{SC}}} \times 50
\]

Content (ppm) of δ-BHC

\[
\text{Content (ppm) of} \ \delta-BHC = \frac{\text{amount (g) of } \delta-BHC}{M} \times \frac{A_{\text{TD}}}{A_{\text{SD}}} \times 50
\]

Content (ppm) of o,p′-DDT

\[
\text{Content (ppm) of} \ o,p′-DDT = \frac{\text{amount (g) of } o,p′-DDT}{M} \times \frac{A_{\text{TE}}}{A_{\text{SE}}} \times 50
\]

Content (ppm) of p,p′-DDT

\[
\text{Content (ppm) of} \ p,p′-DDT = \frac{\text{amount (g) of } p,p′-DDT}{M} \times \frac{A_{\text{TF}}}{A_{\text{SF}}} \times 50
\]
6. Total ash

Ignite previously a crucible of platinum, quartz or porcelain between 500°C and 550°C for 1 hour. Cool, and weigh accurately the crucible. Unless otherwise specified, weigh accurately 2 to 4 g of the test sample for analysis in this crucible, take off the lid or keep it open a little if necessary, heat the crucible at a low temperature at first, then gradually heat to a temperature between 500°C and 550°C, ignite to incinerate the residue for more than 4 hours until no carbonized substance remains in the ash, cool, and weigh accurately the ash. Incinerate repeatedly to constant mass, cool, weigh accurately, and determine the amount (%) of total ash. If a carbonized substance remains and a constant mass cannot be obtained in the above-mentioned method, extract the charred mass with hot water, collect the insoluble residue on filter paper for assay, and incinerate the residue and filter paper until no carbonized substance remains in the ash. Then add the filtrate, evaporate it to dryness, and incinerate. Cool, weigh accurately, and determine the mass (%) of the total ash. If a carbon-free ash cannot be obtained even in this way, moisten the ash with a small amount of ethanol (95), break up the ash with a glass rod, wash the rod with a small amount of ethanol (95), evaporate carefully, and determine the mass of the total ash as described above. A desiccator (silica gel) is used for cooling.

7. Acid-insoluble ash

Add carefully 25 mL of dilute hydrochloric acid to the total ash, boil gently for 5 minutes, collect the insoluble matter on filter paper for assay, and wash thoroughly with hot water. Dry the residue together with the filter paper, and ignite to incinerate in a tared crucible of platinum, quartz or porcelain for 3 hours. Cool in a desiccator (silica gel), weigh, and determine the amount (%) of acid-insoluble ash. When the amount determined exceeds the limit specified, incinerate repeatedly to a constant mass.

8. Extract content

The test for the extract content in crude drugs is performed as directed in the following methods:

8.1. Dilute ethanol-soluble extract

Unless otherwise specified, weigh accurately about 2.3 g of the sample for analysis, extract with 70 mL of dilute ethanol in a suitable flask with occasional shaking for 5 hours, and allow to stand for 16 to 20 hours. Filter, and wash the flask and residue with small portions of dilute ethanol until the filtrate measures 100 mL. Evaporate a 50 mL aliquot of the filtrate to dryness, dry at 105°C for 4 hours, and cool in a desiccator (silica gel). Weigh accurately the amount, multiply it by 2, and determine the amount of dilute ethanol-soluble extract. Calculate the extract content (%) with respect to the amount of the sample on the dried basis, obtained under the loss on drying.

8.2. Water-soluble extract

Proceed as directed in 8.1., using water instead of dilute ethanol, weigh accurately the amount, multiply by 2, and determine the amount of water-soluble extract. Calculate the extract content (%) with respect to the amount of the sample on the dried basis, obtained under the loss on drying.

8.3. Diethyl ether-soluble extract

Unless otherwise specified, dry the test sample for analysis in a desiccator (silica gel) for 48 hours, weigh accurately about 2 g of it, and place in a suitable flask. Add 70 mL of diethyl ether, attach a reflux condenser to the flask, and boil
gently on a water bath for 4 hours. Cool, filter, and wash the flask and the residue with small portions of diethyl ether until the filtrate measures 100 mL. Evaporate a 50 mL aliquot of the filtrate to dryness on a water bath, dry in a desiccator (silica gel) for 24 hours, weigh accurately the amount, multiply it by 2, determine the amount of diethyl ether-soluble extract, and calculate the extract content (\(z\)).

9. Essential oil content

The test of essential oil content in crude drugs is performed as directed in the following method.

9.1. Essential oil determination

Weigh the quantity of the test sample for analysis directed in the monograph in a 1-L hard glass-stoppered flask, and add from 5 to 10 times as much water as the drug. Set up an apparatus for essential oil determination (Fig. 5.01-1), inserting a reflux condenser (Fig. 5.01-2) in the upper mouth of it, and heat the content of the flask in an oil bath between 130°C and 150°C to boiling. The graduated tube of the apparatus is to be previously filled with water to the standard line, and 2.0 mL of xylene is added to the graduated tube. Unless otherwise specified, continue boiling for 5 hours, allow to stand for some time, and open the stopper of the apparatus. Draw off the water slowly until the surface of the oil layer corresponds to the preparation line, and allow it to stand for more than 1 hour at ordinary temperature. Then lower the surface of the oil layer to the zero line, and read the volume (mL) of the oil at ordinary temperature. Subtract the volume (mL) of xylene from the volume of the total oil.

5.02 Microbial Limit Test for Crude Drugs

This chapter provides tests for the qualitative and quantitative estimation of viable microorganisms present in crude drugs. It includes tests for total viable count (aerobic bacteria and fungi) and specified microbial species (Enterobacteria and other gram-negative bacteria, Escherichia coli, Salmonella, and Staphylococcus aureus). Microbial limit test must be carried out under conditions designed to avoid accidental microbial contamination of the preparation during the test. When test specimens have antimicrobial activity, or contain antimicrobial substances, any such antimicrobial properties must be eliminated by means of procedures such as dilution, filtration, neutralization or inactivation. For the test, use a mixture of several portions selected at random from the bulk or from the contents of a sufficient number of containers. If test specimens are diluted with fluid medium, the test should be performed quickly. In performing the test, precautions must be taken to prevent biohazard.

1. Total viable aerobic count

This test determines mesophilic aerobic bacteria and fungi (molds and yeasts) which grow under aerobic conditions. Psychrophilic, thermophilic, basophilic, and anaerobic bacteria, and microorganisms which require specific ingredients for growth, may give a negative result, even if a significant number exists in the test specimens. The test may be carried out using one of the following 4 methods, i.e., pour plate method, spread plate method, serial dilution method (most probable number method) or membrane filtration method. Use an appropriate method depending on the purpose. An automated method may be used for the test presented here, provided it has been properly validated as giving equivalent or better results. Different culture media and temperature are required for the growth of bacteria and fungi (molds and yeasts). The serial dilution method is applicable only to the enumeration of bacteria.

1.1. Sampling and Preparation of the test specimens

Unless otherwise specified, samples should be taken by the following methods.

(i) When crude drugs to be sampled are small-sized, cut or powdered, 50 to 250 g of sample should be taken after mixing thoroughly.

(ii) When crude drugs to be sampled are large-sized, 250 to 500 g of sample should be taken after mixing thoroughly and cutting.

(iii) When the mass of each single piece of the crude drug is not less than 100 g, not less than 5 pieces should be taken for a sample, or not less than 500 g of the sample should be taken after cutting to a suitable size and mixing thoroughly. If necessary, cut more for use.

(iv) When crude drugs to be sampled are in the form of a solution or a preparation, the sample should be taken after mixing thoroughly.

(v) An insoluble solid should be taken after reducing the substance to a moderately fine powder.

1.2. Preparation of the test fluid

Phosphate Buffer, pH 7.2, Buffered Sodium Chloride-Peptone Solution, pH 7.0 or fluid medium used for the test is used to suspend or dilute the test specimen. Unless other-
wised specified, usually take 10 g or 10 mL of the test specimen, and suspend or dissolve it in 90 mL of the buffer or fluid medium specified. A test specimen as a suspension must be shaken for 10 minutes. If necessary, for crude drugs to which microorganisms might adhere, repeat the same method and use this as the test fluid. A different quantity or volume may be used if the nature of the test specimen requires it. The pH of the test fluid is adjusted to between 6 and 8. The test fluid must be used within an hour after preparation.

(i) Fluid specimen: Take 10 mL of the test specimen, and suspend or dissolve it in 90 mL of the buffer or fluid medium specified. A different quantity or volume may be used if the nature of the test specimen requires it.

(ii) Insoluble solids: Pulverize the substance to a moderately fine powder, take 10 g of the test specimen, and suspend it in 90 mL of the buffer or fluid medium specified. A different quantity or a larger volume of buffer and fluid medium than indicated may be used for the suspension, if the nature of the test specimen requires it. The suspension may be dispersed well using, if necessary, a mechanical blender. A suitable surface active agent (such as 0.1 w/v % Polysorbate 80) may be added to aid dissolution.

1.3. Test procedures

1.3.1. Pour Plate Method

Use petri dishes 9 to 10 cm in diameter. Use at least two petri dishes for each dilution. Pipet 1 mL of the test fluid or its diluted solution onto each petri dish aseptically. Promptly add to each dish 15 to 20 mL of sterilized agar medium that has previously been melted and kept below 45°C, and mix. Primarily for the detection of aerobic microbes, use Casein Soya Bean Digest Agar Medium. For specimens that consist of fragments of crude drugs, or to control the growth of fungi, TTC TS for aerobic bacterial strains and amphotericin B TS as an antimycotic may be added to the agar. Just prior to use, add 2.5–5 mL of TTC TS or 2 mL of amphotericin B TS per liter of sterile medium and mix. Primarily for the detection of fungi, use one of Sabouraud-Dextrose Agar Medium with Antibiotics, Potato Dextrose Agar Medium with Antibiotics, and GP Agar Medium with Antibiotics. For an agar medium that is suffused with fungi, Rose Bengal TS may be added to the agar. Add 5 mL of Rose Bengal TS per liter of agar medium, mix and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. After the agar solidifies, incubate the plates for at least 5 days at between 30°C and 35°C for aerobic bacteria, and between 20°C and 25°C for fungi. If too many colonies are observed, dilute the fluid as described above so that a colony count of not more than 300 per plate may be expected in the case of aerobic bacteria, and not more than 100 per plate in the case of fungi. If a reliable count is obtained in a shorter incubation time than 5 days, this may be adopted.

1.3.2. Spread Plate Method

On the solidified and dried surface of the agar medium, pipet 0.05 to 0.2 mL of the test fluid and spread it on the surface with a spreader. The diameter of petri dishes, the kind and volume of the medium to be used, TS to be added, temperature and time of incubation, and the method for calculation of total viable count are the same as described in the Pour Plate Method section.

1.3.3. Serial Dilution Method (Most Probable Number Method)

Prepare tubes each containing 9 to 10 mL of Fluid Casein Soya Bean Digest Medium. To each of the first three tubes add 1 mL of the test fluid (containing 0.1 g or 0.1 mL of specimen), resulting in 1 in 10 dilution. To the next three tubes add 1 mL of a 1 in 10 dilution of the fluid, resulting in 1 in 100 dilution. To the next three tubes add 1 mL of a 1 in 100 dilution of the fluid, resulting in 1 in 1000 dilution. If necessary, dilute further. To the last three tubes add 1 mL of the diluent as a control. Incubate the tubes between 30°C and 35°C for not less than 5 days. The control tubes should show no microbial growth. If the reading of the results is difficult or uncertain, transfer about 0.1 mL to a liquid or solid medium and read the results after a further period of incubation between 30°C and 35°C for 24 to 72 hours. Determine the most probable number of microorganisms per g or per mL of the specimen from Table 5.02-1.

If, for the first column (0.1 g or 0.1 mL of specimen), the number of tubes showing microbial growth is two or less, the most probable number of microorganisms per g or per mL is likely to be less than 100.

1.3.4. Membrane Filtration Method

This method employs membrane filters of appropriate materials, having a normal pore size not greater than 0.45 μm. Filter discs about 50 mm in diameter are recommended, but filters of a different diameter may also be used. Filters, the filtration apparatus, media, etc., should be well sterilized. Usually, take 20 mL of the test fluid (containing 2 g of test specimen), transfer 10 mL of the solution to each of two membrane filters, and filter. If necessary, dilute the pretreated preparation so that a colony count of 10 to 100 may be expected. After the filtration of the test fluid, wash each membrane by filtering through it three or more times with a suitable liquid such as Buffered Sodium Chloride-Peptone Solution, pH 7.0, Phosphate Buffer, pH 7.2, or the fluid medium to be used. The volume of the washing to be used is approximately 100 mL each time, but if the filter disc is not about 50 mm in diameter, the volume may be adjusted according to the size of the filter. For fatty substances, the

washings may contain a suitable surface-active agent such as Polysorbate 80. Put one of the membrane filters, intended primarily for the enumeration of aerobic bacteria, on the surface of a plate of Casein Soya Bean Digest Agar Medium and the other, intended primarily for the enumeration of fungi, on the surface of a plate of one of Sabouraud-Dextrose Agar Medium with Antibiotics, Potato Dextrose Agar Medium with Antibiotics, and GP Agar Medium with Antibiotics. After incubation of the plates for at least 5 days, at between 30°C and 35°C in the test for the detection of aerobic bacteria and between 20°C and 25°C in the test for fungi, count the number of colonies that are formed. If a reliable count is obtained in a shorter incubation time than 5 days, this may be adopted.

1.4. Effectiveness of culture media and confirmation of antimicrobial substances

Use microorganisms of the following strains or their equivalent. Grow them in Casein Soya Bean Digest Agar Medium between 30°C and 35°C for aerobic bacteria and between 20°C and 25°C for Candida albicans.

Escherichia coli, NBRC 3972, ATCC 8739, NCIMB 8545, etc.

Bacillus subtilis, NBRC 3134, ATCC 6633, NCIMB 8054, etc.

Staphylococcus aureus, NBRC 13276, ATCC 6538, NCIMB 9518, etc.

Candida albicans, NBRC 1393, NBRC 1594, ATCC 2091, ATCC 10231, etc.

Dilute portions of each of the cultures using Buffered Sodium Chloride-Peptone Solution, pH 7.0, or Phosphate Buffer, pH 7.2 to prepare test suspensions containing 50 to 200 cfu per mL. Growth-promoting qualities are tested by inoculating 1 mL of each microorganism into each medium. The test media are satisfactory if clear evidence of growth appears in all inoculated media after incubation at the indicated temperature for 5 days. When a count of test organisms with a test specimen is less than 1/5 of that without the test specimen, any such effect must be eliminated by dilution, filtration, neutralization or inactivation. To confirm the sterility of the medium and of the diluent and the aseptic performance of the test, carry out the total viable count method using sterile Buffered Sodium Chloride-Peptone Solution, pH 7.0 or Phosphate Buffer, pH 7.2 as the control.

2. Test for the detection of specified microorganisms

Enterobacteria and certain other gram-negative bacteria, Escherichia coli, Salmonella and Staphylococcus aureus, are included as target strains of the test.

2.1. Sampling and Preparation of the test specimens

Refer to the paragraph on 1.1. Sampling and Preparation of the test specimens.

2.2. Preparation of the test fluid

If necessary, refer to the paragraph on 1.2. Preparation of the test fluid. When test specimens are prepared, use the medium designated in each test, unless otherwise specified. If necessary, eliminate antimicrobial substances so as to permit growth of the inocula, and adjust the quantity of test specimen or increase the volume of medium to suitable values.

2.3. Test Procedure

2.3.1. Enterobacteria and certain other gram-negative bacteria

2.3.1.1. Detection of bacteria

To 10 g or 10 mL of the test specimen add 90 mL of Fluid Lactose Medium to form a suspension or solution. Transfer 10 mL to 90 mL of Fluid Enterobacteria Enrichment Broth-Mossel Medium and incubate at between 35°C and 37°C for 18 to 24 hours. Mix by gently shaking the container, take a portion by means of an inoculating loop, and streak it on the surface of Violet Red Bile Glucose Agar. Incubate at between 35°C and 37°C for 18 to 24 hours. If red or reddish colonies are found, the specimen may contain Enterobacteria and certain other gram-negative bacteria.

2.3.1.2. Quantitative evaluation

If Enterobacteria and certain other gram-negative bacteria are found, to 10 g or 10 mL of the test specimen add 90 mL of Fluid Lactose Medium to form a suspension or solution. Transfer 1 mL of the test fluid (containing 0.1 g or 0.1 mL of specimen) to a tube containing 9 mL of Fluid Enterobacteria Enrichment Broth-Mossel Medium, and mix. Next, transfer 1 mL of the test fluid (containing 0.01 g or 0.01 mL of specimen) to a tube containing 9 mL of Fluid Enterobacteria Enrichment Broth-Mossel Medium, and mix. Furthermore, transfer 1 mL of the test fluid (containing 1 mg or 1 μL of specimen) to a tube containing 9 mL of Fluid Enterobacteria Enrichment Broth-Mossel Medium, and mix. Incubate the tubes at between 35°C and 37°C for 18 to 24 hours, take a portion by means of an inoculating loop, and streak it on the surface of Violet Red Bile Glucose Agar. Incubate at between 35°C and 37°C for 18 to 24 hours. If red or reddish colonies are found, this constitutes a positive result. Note the smallest quantity of the product which gives a positive result and the largest quantity that gives a negative result. Determine from Table 5.02-2 the probable number of microorganisms.

2.3.2. Escherichia coli

2.3.2.1. Detection of bacteria

To 10 g or 10 mL of the test specimen add 90 mL of Fluid Lactose Medium to make a suspension or solution. Transfer 1 mL to a fermentation tube containing 9 to 10 mL of Fluid EC Medium and incubate the tube at 44.5 ± 0.2°C for 24 ± 2 hours in a water bath. If gas bubbles are not found, the specimen meets the requirements of the test for absence of Escherichia coli. If gas bubbles are found, take a portion by means of an inoculating loop, and streak it on the surface of EMB Agar Medium. Incubate at between 30°C and 35°C for 18 to 24 hours. Upon examination, if none of the colonies exhibits both a characteristic metallic sheen and a blue-black appearance under transmitted light, the specimen meets the requirements of the test for absence of Escherichia coli. Confirm any suspect colonies on the plate by means of the IMViC test. (Indole production test, Methyl red reaction test, Voges-Proskauer test, and Citrate utilization test); colonies which exhibit the pattern of either [+ + + −] or [− + + −] are judged as Escherichia coli. Rapid detection kits for Escherichia coli may also be used.

2.3.2.2. Quantitative evaluation

If Escherichia coli is found, prepare tubes each containing 9 to 10 mL of Fluid EC Medium. Use three tubes for each dilution. To 10 g or 10 mL of the test specimen add 90 mL of Fluid Lactose Medium and suspend or dissolve. To each of the first three fermentation tubes add 1 mL of the test fluid (containing 0.1 g or 0.1 mL of specimen), resulting in 1 in 10 dilution. To the next three fermentation tubes add 1 mL of 1 in 10 dilution of the fluid, resulting in 1 in 100 dilution. To the next three fermentation tubes add 1 mL of a 1 in 100 dilution of the fluid, resulting in 1 in 1000 dilution. To the last
three fermentation tubes add 1 mL of the diluent as a control. Incubate the tubes at 44.5 ± 0.2°C for 24 ± 2 hours in a water bath. If gas bubbles are found, take a portion by means of an inoculating loop, and streak it on the surface of EMB Agar Medium. Incubate at between 30°C to 35°C for 18 to 24 hours. Upon examination, colonies of Gram-negative organisms show both a characteristic metallic sheen and a blue-black appearance under transmitted light. Determine the most probable number of microorganisms per g or per mL of the specimen from Table 5.02-1.

2.3.3. Salmonella

As in the case of the detection of *Escherichia coli*, to 10 g or 10 mL of the test specimen add 90 mL of Fluid Lactose Medium to form a suspension or solution. Incubate at between 30°C to 35°C for 24 to 72 hours. Examine the medium for growth, and if growth is apparent, mix by gentle shaking, then pipet 1 mL portions, respectively, into 10 mL of Fluid Selenite-Cystine Medium and Fluid Tetrathionate Medium, and incubate for 12 to 24 hours. 10 mL of Fluid Selenite-Cystine Medium may be replaced by the same volume of Fluid Rappaport Medium. After the incubation, streak portions from both the fluid media on the surface of at least two of Brilliant Green Agar Medium, XLD Agar Medium, and Bismuth Sulfite Agar Medium, and incubate at between 30°C and 35°C for 24 to 48 hours. Upon examination, if none of the colonies conforms to the description given in Table 5.02-3, the specimen meets the requirements of the test for the absence of the genus *Salmonella*. If colonies of Gram-negative rods matching the description in Table 5.02-3 are found, transfer suspect colonies individually, by means of an inoculating wire, to a slant of TSI Agar Medium using both surface and deep inoculation. Incubate at between 35°C and 37°C for 18 to 24 hours. The presence of genus *Salmonella* is confirmed if, in the deep culture but not in the surface culture, there is a change of color from red to yellow and usually formation of gas with or without production of hydrogen sulfide. Precise identification and typing of genus *Salmonella* may be carried out by using appropriate biochemical and serological tests additionally, including an identification kit.

2.3.4. *Staphylococcus aureus*

To 10 g or 10 mL of the test specimen add 90 mL of Fluid Casein Soya Bean Digest Medium, or another suitable fluid medium without antimicrobial activity, to form a suspension or solution. Incubate the fluid containing the specimen at between 30°C and 35°C for 24 to 48 hours, and pipet 1 mL into 9 mL of Fluid Casein Soya Bean Digest Medium with 7.5% sodium chloride. If, upon examination, growth is apparent, use an inoculating loop to streak a portion of the medium on the surface of one of Vogel-Johnson Agar Medium, Baird-Parker Agar Medium, or Mannitol-Salt Agar Medium, and incubate at between 30°C and 35°C for 24 to 48 hours. Upon examination, if no colonies of Gram-positive rods having the characteristics listed in Table 5.02-4 are found, the specimen meets the requirements of the test for the absence of *Staphylococcus aureus*. Confirm any suspect colonies as *Staphylococcus aureus* by means of the coagulate test. With the aid of an inoculating loop, transfer suspect colonies to individual tubes, each containing 0.5 mL of mammalian, preferably rabbit or horse, plasma with or without suitable additives. Incubate in a thermostat at 37 ± 1°C. Examine the coagulation after 3 hours and subsequently at suitable intervals up to 24 hours. Test positive and negative controls simultaneously. If no coagulation is observed, the specimen meets the requirements of the test for the absence of *Staphylococcus aureus*.

2.4. Effectiveness of culture media and confirmation of antimicrobial substances

Grow the test strains listed in Table 5.02-5 in the media indicated at between 30°C and 35°C for 18 to 24 hours. Dilute portions of each of the cultures using Buffered Sodium

*Salmonella* strains of weak or no pathogenicity may be used. *Salmonella* typhi may not be used.
Chloride-Peptone Solution, pH 7.0, Phosphate Buffer, pH 7.2, or medium indicated for each bacterial strain to make
test suspensions containing about 1000 CFU per mL. As occa-
sion demands, using a mixture of 0.1 mL of each suspen-
sion of Escherichia coli, Salmonella and Staphylococcus aureus
containing about 1000 CFU, test the validity of the medium
and the presence of antimicrobial substances in the
presence or absence of the specimen.

2.5. Retest
For the purpose of confirming a doubtful result, a retest is
conducted using a test specimen 2.5 times the first test speci-
men. Proceed as directed under Test procedure, but make
allowance for the larger specimen size, for example by ad-
justing the volume of the medium.

3. Buffer solution, media and test solution (TS)
Buffer solution, media and TS used for the microbial limit
test are described below. Other media may be used if they
have similar nutritive ingredients, and selective and growth-
promoting properties for the microorganisms to be tested.

3.1. Buffer solution
(i) Phosphate Buffer, pH 7.2
For use, dilute the Stock Solution with water in the ratio
of 1 to 800, and sterilize at 121°C for 15 to 20 minutes.
Stock Solution: Dissolve 34 g of potassium dihydrogen
phosphate in about 500 mL of water. Adjust to pH 7.1 to 7.3
by the addition of 175 mL of sodium hydroxide TS, add
water to make 1000 mL, and use this solution as the stock
solution. After sterilization by heating in an autoclave, store
under refrigeration.

(ii) Buffered Sodium Chloride-Peptone Solution, pH 7.0
Potassium dihydrogen phosphate 3.6 g
Disodium hydrogen phosphate dihy-
drate (equivalent to 0.067 mol
phosphate) 7.2 g
Sodium chloride 4.3 g
Peptone (animal tissue
or casein) 1.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
6.9 – 7.1. Polysorbate 20 or 80 (0.1 to 1.0 w/v%)
may be added.

3.2. Media
(i) Casein Soya Bean Digest Agar Medium
Pancreatic digest of casein 15.0 g
Soybean peptone 5.0 g
Sodium chloride 5.0 g
Agar 15.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
7.1 – 7.5.

(ii) Fluid Casein Soya Bean Digest Medium
Pancreatic digest of casein 17.0 g
Soybean peptone 3.0 g
Sodium chloride 5.0 g
Dipotassium hydrogen phosphate 2.5 g
Glucose monohydrate 2.5 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
7.1 – 7.5.

(iii) Sabouraud-Dextrose Agar Medium with Antibiotics
Glucose 40.0 g
Peptone (animal tissue and casein, 1:1) 10.0 g
Agar 15.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes, pH after sterilization:
5.4 – 5.8. Just prior to use, add 0.10 g of benzylpenicillin
potassium and 0.10 g of tetracycline per liter of medium as
sterile solutions or, alternatively, add 50 mg of chloram-
phenicol per liter of medium.

(iv) Potato Dextrose Agar Medium with Antibiotics
Potato extract 4.0 g
Glucose 20.0 g
Agar 15.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
5.4 – 5.8. Just prior to use, add 0.10 g of benzylpenicillin
potassium and 0.10 g of tetracycline per liter of medium as
sterile solutions or, alternatively, add 50 mg of chloram-
phenicol per liter of medium.

(v) GP (Glucose-peptone) Agar Medium with Antibio-
tics
Glucose 20.0 g
Yeast extract 2.0 g
Magnesium sulfate heptahydrate 0.5 g
Peptone 5.0 g
Potassium dihydrogen phosphate 1.0 g
Agar 15.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
5.6 – 5.8. Just prior to use, add 0.10 g of benzylpenicillin
potassium and 0.10 g of tetracycline per liter of medium as
sterile solutions or, alternatively, add 50 mg of chloram-
phenicol per liter of medium.

(vi) Fluid Lactose Medium
Meat extract 3.0 g
Gelatin peptone 5.0 g
Lactose monohydrate 5.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
6.7 – 7.1. After sterilization, cool immediately.

(vii) Fluid EC Medium
Peptone 20.0 g
Lactose monohydrate 5.0 g
Bile salts 1.5 g
Dipotassium hydrogen phosphate 4.0 g
Potassium dihydrogen phosphate 1.5 g
Sodium chloride 5.0 g
Water 1000 mL
Mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization:
6.8 – 7.0. After sterilization cool immediately. If gas remains
in durham tube after cool, do not use the tube.

(viii) EMB (Eosin-Methylene Blue) Agar Medium
Gelatin peptone 10.0 g
Dipotassium hydrogen phosphate 2.0 g
Lactose monohydrate 10.0 g
Agar 15.0 g
(x) Fluid Enterobacteria Enrichment Broth-Mossel Medium

- Gelatin peptone: 10.0 g
- Glucose monohydrate: 5.0 g
- Bile salts: 20.0 g
- Potassium dihydrogen phosphate: 2.0 g
- Disodium hydrogen phosphate dihydrate: 8.0 g
- Brilliant green: 15 mg
- Water: 1000 mL

Mix all the components, boil at 100°C for 30 minutes, and cool immediately. pH after boiling: 7.0 – 7.4. Do not sterilize in an autoclave.

(xi) Fluid Selenite-Cystine Medium

- Gelatin peptone: 5.0 g
- Lactose monohydrate: 4.0 g
- Trisodium phosphate dodecahydrate: 10.0 g
- Sodium selenite: 4.0 g
- L-Cystine: 10 mg
- Water: 1000 mL

Mix all the components, heat to dissolve. Final pH: 6.8 – 7.2. Do not sterilize.

(xii) Fluid Tetrathionate Medium

- Pancreatic digest of casein: 2.5 g
- Animal tissue peptone: 2.5 g
- Sodium deoxycholate: 1.0 g
- Calcium carbonate: 10.0 g
- Sodium thiosulfate pentahydrate: 30.0 g
- Water: 1000 mL

Heat the solution of solids to boiling. On the day of use, add a solution prepared by dissolving 5 g of potassium iodide and 6 g of iodine in 20 mL of water. Then add 10 mL of a solution of brilliant green (1 in 1000), and mix. Do not heat the medium after adding the brilliant green solution.

(xiii) Fluid Rappaport Medium

- Soybean peptone: 5.0 g
- Sodium chloride: 8.0 g
- Potassium dihydrogen phosphate: 1.6 g
- Malachite green oxalate: 0.12 g
- Magnesium chloride hexahydrate: 40.0 g
- Water: 1000 mL

Dissolve malachite green oxalate and magnesium chloride hexahydrate, and the remaining solids separately in the water, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. For the use, mix the both solutions after sterilization. Final pH: 5.4 – 5.8.
nium iron (II) sulfate hexahydrate may be used.

(xviii) Fluid Casein Soya Bean Digest Medium with 7.5% Sodium Chloride

- Pancreatic digest of casein: 17.0 g
- Soybean peptone: 3.0 g
- Sodium chloride: 75.0 g
- Dipotassium hydrogen phosphate: 2.5 g
- Glucose monohydrate: 2.5 g
- Water: 1000 mL

Add the sodium chloride 70.0 g for (ii) Fluid Casein Soya Bean Digest Medium (containing 5 g of sodium chloride), mix all the components, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization: 7.1 – 7.5.

(xix) Vogel-Johnson Agar Medium

- Pancreatic digest of casein: 10.0 g
- Yeast extract: 5.0 g
- D-Mannitol: 10.0 g
- Dipotassium hydrogen phosphate: 5.0 g
- Lithium chloride: 5.0 g
- Glycine: 10.0 g
- Phenol red: 25 mg
- Agar: 16.0 g
- Water: 1000 mL

Mix all the components, and boil for 1 minute to make solution. Sterilize by heating in an autoclave at 121°C for 15 to 20 minutes, and cool to between 45°C and 50°C. pH after sterilization: 7.0 – 7.4. To this solution add 20 mL of sterile potassium tellurite solution (1 in 100), and mix.

(xx) Baird-Parker Agar Medium

- Pancreatic digest of casein: 10.0 g
- Meat extract: 5.0 g
- Yeast extract: 1.0 g
- Lithium chloride: 5.0 g
- Glycine: 12.0 g
- Sodium pyruvate: 10.0 g
- Agar: 20.0 g
- Water: 950 mL

Mix all the components. Heat the mixture with frequent agitation, and boil for 1 minute. Sterilize by heating in an autoclave at 121°C for 15 to 20 minutes, and cool to between 45°C and 50°C. pH after sterilization: 6.6 – 7.0. To this solution add 10 mL of sterile potassium tellurite solution (1 in 100) and 50 mL of egg-yolk emulsion. Mix gently, and pour into petri dishes. Prepare the egg-yolk emulsion by mixing egg-yolk and sterile saline with the ratio of about 30% to 70%.

(xxi) Mannitol-Salt Agar Medium

- Pancreatic digest of casein: 5.0 g
- Animal tissue peptone: 5.0 g
- Bovine meat extract: 1.0 g
- D-Mannitol: 10.0 g
- Sodium chloride: 75.0 g
- Phenol red: 25 mg
- Agar: 15.0 g
- Water: 1000 mL

Mix all the components. Heat with frequent agitation, and boil for 1 minute. Sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. pH after sterilization: 7.2 – 7.6.

3.3. Reagents/Testing solutions

(i) Amphotericin B powder: Amphotericin B added sodium deoxycholic acid, sterilized by γ-ray. Amphotericin B TS Dissolve 22.5 mg of amphotericin B powder in 9 mL of sterile purified water.

(ii) Bile salts: Yellow-brown powder made from dried bile of animal, consist of sodium taurocholic acid and sodium glycocholic acid, and containing not less than 45% of cholic acid. pH of 5% solution: 5.5 – 7.5.

(iii) Rose Bengal TS: Dissolve 1 g of rose bengal in water to make 100 mL. Rose bengal C₂₅H₃₈Cl₂I₄Na₂O₅. [Special class] Red-brown powder, purple-red solution in water.

(iv) TTC TS: Dissolve 0.8 g of 2,3,5-triphenyl-2H-tetrazolium chloride in water to make 100 mL, distribute in small tubes, and sterilize by heating in an autoclave at 121°C for 15 to 20 minutes. Store in light-resistant containers.

6. Tests for Preparations

6.01 Test for Metal Particles in Ophthalmic Ointments

Test of Metal Particles in Ophthalmic Ointments is a method to test the existence of foreign metal particles in the ophthalmic ointments described in General Rules for Preparations.

1. Preparation of Test Sample

The test should be carried out in a clean place. Take 10 ophthalmic ointments to be tested, and extrude 5 g each of their contents into separate flat-bottomed petri dishes 60 mm in diameter. Cover the dishes, and heat between 85°C and 110°C for 2 hours to dissolve bases completely. Allow the samples to cool to room temperature without agitation to solidify the contents. When the amount of the content is less than 5 g, extrude the contents as completely as practicable, and proceed in the same manner as described above.

2. Procedure

Invert each dish on the stage of a suitable microscope previously adjusted to provide not less than 40 times magnifications and equipped with an eyepiece micrometer disk. Each dish is illuminated from above 45° relative to the plane of the dish. Examine the entire bottom of each dish for metal particles, and record the total number of particles, measuring 50 μm or more in any dimension.

Note: Use petri dishes with a clean bottom and free from foams and scratches, and if possible, the walls are at right angles with the bottom.

3. Evaluation

The preparation complies with the test if the total number...
of metal particles of a size equal to or greater than 50 μm found in 10 units tested, is not more than 50, and also the number of dishes containing more than 8 particles is not more than 1. If this requirement is not met, repeat the test with a further 20 units in the same manner, and if the total number of the particles found in the total of 30 units is not more than 150, and also the number of dishes containing more than 8 particles is not more than 3, the preparation complies with the test.

6.02 Uniformity of Dosage Units

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia. The parts of the text that are not harmonized are marked with symbols (••). The term “Uniformity of dosage unit” is defined as the degree of uniformity in the amount of the drug substance among dosage units. Therefore, the requirements of this chapter apply to each drug substance being comprised in dosage units containing one or more drug substances, unless otherwise specified elsewhere in this Pharmacopoeia.

To ensure the consistency of dosage units, each unit in a batch should have a drug substance content within a narrow range around the label claim. Dosage units are defined as dosage forms containing a single dose or a part of a dose of a drug substance in each dosage unit. The Uniformity of Dosage Units specification is not intended to apply to suspensions, emulsions, or gels in unit-dose containers intended for external, cutaneous administration.

The uniformity of dosage units can be demonstrated by either of two methods, Content Uniformity or Mass variation (see Table 6.02-1.). The test for Content Uniformity of preparations presented in dosage units is based on the assay of the individual contents of drug substance(s) of a number of dosage units to determine whether the individual contents are within the limits set. The Content Uniformity method may be applied in all cases.

The test for Mass Variation is applicable for the following dosage forms:

(i) solutions enclosed in unit-dose containers and into soft capsules •in which all components are perfectly dissolved•;

(ii) solids (including powders, granules and sterile solids) that are packaged in single-unit containers and contain no active or inactive added substances;

(iii) solids (including sterile solids) that are packaged in single-unit containers, with or without active or inactive added substances, that have been prepared from true solutions •in which all components are perfectly dissolved•, and freeze-dried in the final containers and are labeled to indicate this method of preparation; and

(iv) hard capsules, uncoated tablets, or film-coated tablets, containing 25 mg or more of a drug substance comprising 25% or more, by weight, of the dosage unit or, in the case of hard capsules, the capsule contents, •or in the case of film-coated tablets, the pre-coated tablets•, except that uniformity of other drug substances present in lesser proportions is demonstrated by meeting Content Uniformity requirements.

The test for Content Uniformity is required for all dosage forms not meeting the above conditions for the Mass Variation test. Alternatively, products listed in item (4) above that do not meet the 25 mg/25% threshold limit may be tested for uniformity of dosage units by Mass Variation instead of the Content Uniformity test if the concentration relative standard deviation (RSD) of the drug substance in the final dosage units is not more than 2%, based on process validation data and development data, and if there has been regulatory approval of such a change. The concentration RSD is the RSD of the concentration per dosage unit (w/w

or w/v), where concentration per dosage unit equals the assay result per dosage unit divided by the individual dosage unit weight. See the RSD formula in Table 6.02-2.

1. Content Uniformity

Select not less than 30 units, and proceed as follows for the dosage form designated.

Where different procedures are used for assay of the preparation and for the content uniformity test, it may be necessary to establish a correction factor to be applied to the results of the latter.

(i) Solid dosage forms: Assay 10 units individually using an appropriate analytical method. Calculate the acceptance value (see Table 6.02-2).
(ii) Liquid dosage forms: Assay 10 units individually using an appropriate analytical method. Carry out the assay on the amount of well-mixed material that is removed from an individual container in conditions of normal use and express the results as delivered dose. Calculate the acceptance value (see Table 6.02-2).

1.1. Calculation of Acceptance Value

Calculate the acceptance value by the formula:

\[ |M - X| + ks \]

in which the terms are as defined in Table 6.02-2.

2. Mass Variation

Mass Variation is carried out based on the assumption that the concentration (mass of drug substance per mass of dosage unit) is uniform in a lot.

Carry out an assay for the drug substance(s) on a representative sample of the batch using an appropriate analytical method. This value is result A, expressed as % of label claim (see Calculation of the Acceptance Value). Select not less than 30 dosage units, and proceed as follows for the dosage form designated.

(i) Uncoated or film-coated Tablets: Accurately weigh 10 tablets individually. Calculate the content, expressed as % of label claim, of each tablet from the individual masses of the dosage units tested, and the result of the assay. Calculate the acceptance value.
(ii) Hard Capsules: Accurately weigh 10 capsules individually, taking care to preserve the identity of each capsule. Remove the contents of each capsule by suitable means. Accurately weigh the emptied shells individually, and calculate for each capsule the net mass of its contents by subtracting the mass of the shell from the respective gross mass. Calculate the drug substance content of each capsule from the mass of the individual capsules and the result of the assay. Calculate the acceptance value.
(iii) Soft Capsules: Accurately weigh the 10 intact capsules individually to obtain their gross masses, taking care to preserve the identity of each capsule. Then cut open the capsules by means of a suitable clean, dry cutting instrument such as scissors or a sharp open blade, and remove the contents by washing with a suitable solvent. Allow the occluded solvent to evaporate from the shells at room temperature over a period of about 30 min, taking precautions to avoid uptake or loss of moisture. Weigh the individual shells, and calculate the net contents. Calculate the drug substance content in each capsule from the mass of product removed from the individual capsules and the result of the assay. Calculate the acceptance value.
(iv) Solid dosage forms other than tablets and capsules: Proceed as directed for Hard Capsules, treating each dosage unit as described therein. Calculate the acceptance value.
(v) Liquid dosage forms: Accurately weigh the amount of liquid that is removed from each of 10 individual containers in conditions of normal use. Calculate the drug substance content in each container from the mass of product removed from the individual containers and the result of the assay. Calculate the acceptance value.

2.1. Calculation of Acceptance Value

Calculate the acceptance value as shown in Content Uniformity, except that \( X \) is replaced with \( A \), and that the individual contents of the dosage units are replaced with the individual estimated contents defined below.

\[ x_1, x_2, \ldots, x_n \] individual estimated contents of the dosage units tested, where

\[ x_i = w_i \times \frac{A}{W} \]

\( w_1, w_2, \ldots, w_n \) individual masses of the dosage units tested, \( A \) = content of drug substance (% of label claim) obtained using an appropriate analytical method.
\( W \) = mean of individual masses (\( w_1, w_2, \ldots, w_n \)).

3. Criteria

Apply the following criteria, unless otherwise specified.
(i) Solid and Liquid dosage forms: The requirements for dosage uniformity are met if the acceptance value of the first 10 dosage units is less than or equal to 1%, and that the individual contents of the dosage units are replaced with the individual estimated contents defined below.
(ii) Solid and Liquid dosage forms: The requirements are met if the final acceptance value of the 30 dosage units is less than or equal to 1% and no individual content of the dosage unit is less than \((1 - L_2 \times 0.01)M\) nor more than 
\((1 + L_2 \times 0.01)M\) in Calculation of Acceptance Value under Content Uniformity or under Mass Variation. Unless otherwise specified, \( L_1 \) is 15.0 and \( L_2 \) is 25.0.

### 6.03 Particle Size Distribution

#### Test for Preparations

Particle Size Distribution Test for Preparations is a method to determine the particle size distribution of preparations described in General Rules for Preparations.

1. Procedure

The test is performed employing No. 18 (850 μm) and No. 30 (500 μm) sieves with the inside diameter of 75 mm.

Weigh accurately 10.0 g of sample to be tested, and place on the uppermost sieve which is placed on the other sieves described above and a close-fitting receiving pan and is covered with a lid. Shake the sieves in a horizontal direction for 3 minutes, and tap slightly at intervals. Weigh the amount remaining on each sieve and in the receiving pan.

### 6.04 Test for Acid-neutralizing Capacity of Gastrointestinal Medicines

Test for Acid-neutralizing Capacity of Gastrointestinal Medicines is a test to determine the acid-neutralizing capaci-
ty of a medicine, as a crude material or preparation, which reacts with the stomach acid and exercises an acid control action in the stomach. When performing the test according to the following procedure, the acid-neutralizing capacity of a crude material is expressed in terms of the amount (mL) of 0.1 mol/L hydrochloric acid VS consumed per g of the material, and that of a preparation is expressed by the amount (mL) of 0.1 mol/L hydrochloric acid VS consumed per dose per day (when the daily dose varies, the minimum dose is used).

1. Preparation of sample
   A crude material and a solid preparation which conforms to Powders in the General Rules for Preparations: may be used, without any treatment, as the sample. Preparations in dose-unit packages: weigh accurately the content of not less than 20 packages, calculate the average mass of the content for a daily dose, mix uniformly, and use the mixture as the sample. Granules in dose-unit packages and other solid preparations which do not conform to Powders in the General Rules for Preparations: weigh accurately the content of not less than 20 packages, calculate the average mass of the content for a daily dose, powder it, and use as the sample. Granules not in dose-unit packages and other solid preparations which do not conform to Powders in the General Rules for Preparations: take not less than 20 doses, powder it, and use as the sample. Capsules and tablets: take not less than 20 doses, weigh accurately, calculate the average mass for a daily dose, powder it, and use as the sample. Liquid preparations: shake well, and use as the sample.

2. Procedure
   Take an amount of the sample so that \( a \) in the equation falls between 20 mL and 30 mL, and perform the test.

   Accurately weigh the sample of the crude material or preparation, and place it in a glass-stoppered, 200-mL flask. Add exactly 100 mL of 0.1 mol/L hydrochloric acid VS, stopper tightly, shake at 37 ± 9°C for 1 hour, and filter. Take precaution against gas to be generated on the addition of 0.1 mol/L hydrochloric acid VS, and stopper tightly. After cooling, filter the solution again, if necessary. Pipet 50 mL of the filtrate, and titrate \( \Delta \) the excess hydrochloric acid with 0.1 mol/L sodium hydroxide VS (pH Determination \( \Delta \), end point: pH 3.5). Perform a blank determination.

   For liquid preparations, pipet the sample in a 100-mL volumetric flask, add water to make 45 mL, then add exactly 50 mL of 0.1 mol/L hydrochloric acid VS while shaking. Add water again to make the solution 100 mL. Transfer the solution to a glass-stoppered, 200-mL flask, wash the residue with 20.0 mL of water, stopper tightly, shake at 37 ± 2°C for 1 hour, and filter. Pipet 60 mL of the filtrate, and titrate \( \Delta \) the excess hydrochloric acid with 0.1 mol/L sodium hydroxide VS (pH Determination \( \Delta \), end point: pH 3.5). Perform a blank determination.

   Acid-neutralizing capacity (amount of 0.1 mol/L hydrochloric acid VS consumed per g or daily dose) (mL)
   \[
   t = (b - a) / f \times 2 \times (l/s)
   \]
   \( a \): Amount (mL) of 0.1 mol/L sodium hydroxide VS consumed
   \( b \): Amount (mL) of 0.1 mol/L sodium hydroxide VS consumed in the blank determination
   \( f \): The molarity coefficient of 0.1 mol/L sodium hydroxide VS

6.05 Test for Extractable Volume of Parenteral Preparations

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia. The parts of the text that are not harmonized are marked with symbols (*, **).

*Test for Extractable Volume of Parenteral Preparations is performed to confirm that a slightly excess volume is filled for the nominal volume to be withdrawn. Injections may be supplied in single-dose containers such as ampoules or plastic bags, or in multi-dose containers filled with a volume of injection which is sufficient to permit administration of the nominal volume declared on the label. The excess volume is determined by the characteristics of the product.

Suspensions and emulsions must be shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20–25°C before measuring the volume.

1. Single-dose containers
   Select one container if the volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding three times the volume to be measured, and fitted with a 21-gauge needle not less than 2.5 cm in length. Expel any air bubbles from the syringe and needle, then discharge the contents of the syringe without reinserting the needle into a standardized dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40% of its graduated volume. Alternatively, the volume of the contents in milliliters may be calculated as the mass in grams divided by the density.

   For containers with a nominal volume of 2 mL or less the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 mL or more may be determined by opening them and emptying the contents directly into the graduated cylinder or tared beaker.

   The volume is not less than the nominal volume in case of containers examined individually, or, in case of containers with a nominal volume of 2 mL or less, is not less than the sum of the nominal volumes of the containers taken collectively.

2. Multi-dose containers
   For injections in multidose containers labeled to yield a specific number of doses of a stated volume, select one container and proceed as directed for single-dose containers using the same number of separate syringe assemblies as the
number of doses specified. The volume is such that each syringe delivers not less than the stated dose.

3. Cartridges and pre-filled syringes
   Select one container if the volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in milliliters calculated as the mass in grams divided by the density. The volume measured for each of the containers is not less than the nominal volume.

4. Parenteral infusions
   Select one container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40% of the nominal volume of the cylinder. Measure the volume transferred. The volume is not less than the nominal volume.

6.06 Foreign Insoluble Matter Test for Injections

Foreign Insoluble Matter Test for Injections is a test method to examine foreign insoluble matters in injections.

1. Method 1.
   This method is applied to either injections in solutions, or vehicles for solid injections to be dissolved before use.
   Clean the exterior of containers, and inspect with the unaided eyes at a position of light intensity of approximately 1000 lx under an incandescent lamp. Injections or vehicles must be clear and free from readily detectable foreign insoluble matters. As to Injections in plastic containers for aqueous injections, the inspection should be performed with the unaided eyes at a position of light intensity of approximately 8000 to 10,000 lx, with an incandescent lamp at appropriate distances above and below the container.

   This method is applied to solid injections to be dissolved before use.
   Clean the exterior of containers, and dissolve the contents with vehicles or with Water for Injection carefully, avoiding any contamination with extraneous foreign substances. The solution thus constituted must be clear and free from foreign insoluble matters that is clearly detectable when inspected with the unaided eyes at a position of light intensity of approximately 1000 lx, right under an incandescent lamp.

6.07 Insoluble Particulate Matter Test for Injections

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopoeia. The parts of the text that are not harmonized are marked with symbols ( *  •).

Insoluble particulate matters in injections and parenteral infusions consist of extraneous, mobile undissolved particles, other than gas bubbles, that are unintentionally present in the solutions.

For the determination of particulate contamination, 2 procedures, Method 1 (Light Obscuration Particle Count Test) and Method 2 (Microscopic Particle Count Test), are specified hereinafter. When examining injections and parenteral infusions for sub-visible particles, Method 1 is preferably applied. However, it may be necessary to test some preparations by Method 1 followed by Method 2 to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for sub-visible particles by one or both of these methods. When Method 1 is not applicable, e.g. in case of preparations having reduced clarity or increased viscosity, the test should be carried out according to Method 2. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate contamination cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if valid inferences are to be drawn from observed data to characterise the level of particulate contamination in a large group of units.

1. Method 1. Light Obscuration Particle Count Test

1.1. Apparatus
   Use a suitable apparatus based on the principle of light blockage which allows an automatic determination of the size of particles and the number of particles according to size. *It is necessary to perform calibration, as well as to demonstrate the sample volume accuracy, sample flow rate, particle size response curve, sensor resolution, and counting accuracy, at least once a year. •

   *1.1.1. Calibration
   Particles to be used for calibration should be subject to particle size sensitivity measurement, using spherical polystyrene particles having at least 5, 10 and 25 μm in diameter (PSL particles) in mono-dispersed suspension. The PSL particles should have either a domestic or international traceability in terms of length, with a level of uncertainty at not greater than 3%. The particles to be used for calibration should be dispersed in particle-free water.

   1.1.1.1. Manual method
   The particle size response of the system to be applied should be determined using at least 3 channels for threshold-voltage setting, according to the half counting method of window moving type. The threshold-voltage window should be ±20% of the measuring particle size. After measuring the sensitivity of response for the designated particle size, the size response curve is prepared by the method indicated by the manufacturer from particle-response measuring point, and threshold-voltage of 5, 10 and 25 μm of the apparatus is obtained.

   1.1.1.2. Electronic method
   In the use of multichannel peak height analyzer, the parti-
The particle size response curve of the apparatus may be obtained by using the software developed by the user or supplied by the instrument manufacturer, whereas the manufacturer or the user should validate the obtainability of the same result as that of the manual method.

1.1.3. Automated method

The particle size resolution of curve obtained should be 763 to 1155 particles per 1 mL.

1.1.2. Sample volume accuracy

Sample volume accuracy should fall within 5% of the measuring value in case the decrease of test solution is measured by the mass method after measuring the test solution of 10 mL.

1.1.3. Sample flow rate

The flow rate of the sample indicated into the sensor should be the observed sample volume and time, and should be confirmed within the range of the manufacturer’s specification for sensor used.

1.1.4. Sensor

There is a possibility of changes of particle size resolution and counting rate of particle-detecting sensor in each sensor by assembling accuracy and parts accuracy even in the same type sensor. The threshold accuracy also needs to be confirmed. Testing should accordingly be performed for each of the particle size resolution, accuracy in counting and threshold setting, using Particle Count Reference Standard Suspension (PSL spheres having mean diameter of approximately 10 μm, of a concentration at 1000 particles/mL ± 10%, not more than 5% of CV value).

During measurement, stirring should be made for assuring the uniformity in sample concentration.

1.1.4.1. Sensor resolution (Particle size resolution of apparatus)

Measurement should be made by either one of the following methods. The difference between the threshold of particle size counting 16% and 84% of the total counts and the test-particle size should be within 10%, whereas, electronic method and automated method should be both validated for obtaining the same result as that of the manual method.

(i) Manual method to obtain the spread of histogram prepared from the counting value of the apparatus.

(ii) Electronic method to obtain the spread of histogram of the classification of system-responding signal by using the multichannel peak height analyzer.

(iii) Automated method to obtain the spread of histogram of responsive signal of the test-particle by using the software prepared by the manufacturer or the user.

1.1.4.2. Particle counting accuracy

Data obtained by counting particles of 5 μm and greater should be 763 to 1155 particles per 1 mL.

1.1.4.3. Threshold accuracy

Particle size calculated from a threshold corresponding to 50% counts for particles of 5 μm and greater should fall within ±5% of the mean diameter of the test particles.

1.2. General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with particle-free water.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of 5 samples of particle-free water, each of 5 mL, according to the method described below. If the number of particles of 10 μm or greater size exceeds 25 for the combined 25 mL, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware and water are suitable for the test.

1.3. Method

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of particle-free water and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing to stand for 2 minutes or sonicating.

For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container to obtain a volume of not less than 25 mL; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with particle-free water or with an appropriate solvent without contamination of particles when particle-free water is not suitable.

Powders for parenteral use are reconstituted with particle-free water or with an appropriate solvent without contamination of particles when particle-free water is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Remove 4 portions, each of not less than 5 mL, and count the number of particles equal to or greater than 10 μm and 25 μm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

1.4. Evaluation

If the average number of particles exceeds the limits, test the preparation by Method 2 (Microscopic Particle Count Test).

Test 1.A—Solutions for injection supplied in containers with a nominal content of equal to or more than 100 mL.

The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per milliliter equal to or greater than 10 μm and does not exceed 3 per milliliter equal to or greater than 25 μm.

Test 1.B—Solutions for injection supplied in containers with a nominal content of less than 100 mL.
The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10 \( \mu m \) and does not exceed 600 per container equal to or greater than 25 \( \mu m \).

2. Method 2. Microscopic Particle Count Test

2.1. Apparatus
Use a suitable binocular microscope, filter assembly for retaining particulate contamination and membrane filter for examination.

The microscope is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, two suitable illuminators to provide episcopic illumination in addition to oblique illumination, and is adjusted to 100 ± 10 magnifications. The ocular micrometer is a circular diameter graticule (see Fig. 6.07-1) and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10 \( \mu m \) and 25 \( \mu m \) in diameter at 100 magnifications, and a linear scale graduated in 10 \( \mu m \) increments. It is calibrated using a stage micrometer that is certified by either a domestic or international standard institution. A relative error of the linear scale of the graticule within ± 2 per cent is acceptable. The large circle is designated the graticule field of view (GFOV).

Two illuminators are required. One is an episcopic bright-field illuminator internal to the microscope, the other is an external, focussable auxiliary illuminator adjustable to give reflected oblique illumination at an angle of 10° to 20°.

The filter assembly for retaining particulate contamination consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark gray in color, non-gridded or gridded, and 1.0 \( \mu m \) or finer in nominal pore size.

2.2. General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with particle-free water.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of a 50 mL volume of particle-free water according to the method described below. If more than 20 particles 10 \( \mu m \) or larger in size or if more than 5 particles 25 \( \mu m \) or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter and water are suitable for the test.

2.3. Method

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of particle-free water and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units is combined in a cleaned container; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with particle-free water or with an appropriate solvent without contamination of particles when particle-free water is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral use are constituted with particle-free water or with an appropriate solvent without contamination of particles when particle-free water is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several milliliters of particle-free water. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If needed add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of particle-free water. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the filter in a petri dish and allow the filter to air-dry with the cover slightly ajar. After the filter has been dried, place the petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10 \( \mu m \) and the number of particles that are equal to or greater than 25 \( \mu m \). Alternatively, partial filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by transforming mentally the image of each particle into a circle and then comparing it to the 10 \( \mu m \) and 25 \( \mu m \) graticule reference circles. Thereby the
particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.

In performing the microscopic particle count test (Method 2) do not attempt to size or enumerate amorphous, semiliquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane filter. These materials show little or no surface relief and present a gelatinous or film-like appearance. In such cases the interpretation of enumeration may be aided by testing a sample of the solution by Method 1.

2.4. Evaluation
Test 2.4.1—Solutions for injection supplied in containers with a nominal content of *equal to or* more than 100 mL
The preparation complies with the test if the average number of particles present in the units tested does not exceed 12 per milliliter equal to or greater than 10 μm and does not exceed 2 per milliliter equal to or greater than 25 μm.
Test 2.4.2—Solutions for injection supplied in containers with a nominal content of less than 100 mL
The preparation complies with the test if the average number of particles present in the units tested does not exceed 3000 per container equal to or greater than 10 μm and does not exceed 300 per container equal to or greater than 25 μm.

3. Reagents
Particle-free water: The filtered water through a membrane filter with a pore size not exceeding 0.45 μm, containing not more than 5 particles of 10 μm or greater size, and not more than 2 particles of 25 μm or greater size in 10 mL of the insoluble particle number measured by the light obscuration particle counter.

6.08 Insoluble Particulate Matter Test for Ophthalmic Solutions

Insoluble Particulate Matter Test for Ophthalmic Solutions is to examine for the size and the number of insoluble particulate matter in Ophthalmic Solutions.

1. Apparatus
Use a microscope, filter assembly for retaining insoluble particulate matter and membrane filter for determination.
(i) Microscope: The microscope is equipped with a micrometer system, a mobile stage and an illuminator, and is adjusted to 100 magnifications.
(ii) Filter assembly for retaining insoluble particulate matter: The filter assembly for retaining insoluble particulate matter consists of a filter holder made of glass or a proper material incapable of causing any trouble in testing, and a clip. The unit is capable of fitting with a membrane filter 25 mm or 13 mm in diameter and can be used under reduced pressure.
(iii) Membrane filter for testing: The membrane filter is white in color, 25 mm or 13 mm in diameter, not more than 10 μm in nominal pore size and is imprinted with about 3 mm grid marks. Upon preliminary testing, the insoluble particulate matter equal to or greater than 25 μm in size should not be found on the filter. When necessary, wash the filter with water for particulate matter test.

2. Reagents
(i) Water for particulate matter test: Water prepared before use by filtering through a membrane filter with a pore size not exceeding 0.45 μm. It contains not more than 10 particles of 10 μm or grater size in 100 mL.

3. Procedure

3.1. Aqueous ophthalmic solutions
Carry out all operations carefully in clean equipment and facilities which are low in dust. Fit the membrane filter onto the membrane filter holder, and fix them with the clip. Thoroughly rinse the holder inside with water for particulate matter test, and filter under reduced pressure with 200 mL of water for particulate matter test at a rate of 20 to 30 mL per minute. Apply the vacuum until the surface of the membrane filter is free from water, and remove the membrane filter. Place the filter in a flat-bottomed petri dish with the cover slightly ajar, and dry the filter fully at a temperature not exceeding 50°C. After the filter has been dried, place the petri dish on the stage of the microscope. Under a downlight from an illuminating device, adjust the grid of the membrane filter to the coordinate axes of the microscope, adjust the microscope so as to get the best view of the insoluble particulate matter, then count the number of particles that are equal to or greater than 150 μm within the effective filtering area of the filter, moving the mobile stage, and ascertain that the number is not more than 1. In this case the particle is sized on the longest axis.

Fit another membrane filter to the filtration device, and fix them with the clip, then wet the inside of the filter holder with several mL of water for particulate matter test. Clean the outer surface of the container, and mix the sample solution gently by inverting the container several times. Remove the cap, clean the outer surface of the nozzle, and pour the sample solution into a measuring cylinder which has been rinsed well with water for particulate matter test. Repeat the process to prepare 25 mL of the test solution. Pour the test solution into the filter holder along the inner wall of the holder. Apply the vacuum and filter mildly so as to keep the solution always on the filter. As for viscous sample solution, dilute suitably with water for particulate matter test or suitable diluent and then filter as described above. When the amount of the solution on the filter becomes small, add 30 mL of water for particulate matter test or suitable diluent in such manner as to wash the inner wall of the filter holder. Repeat the process 3 times with 30 mL of the water. Apply the vacuum gently until the surface of the membrane filter is free from water. Place the filter in a petri dish, and dry the filter at a temperature below 50°C with the cover slightly ajar. After the filter has been dried, place the petri dish on the stage of the microscope, and count the number of particles which are equal to or larger than 300 μm within the effective filtering area of the filter according to the same procedure of the microscope as described above. In this case the particle is sized on the longest axis.

3.2. Ophthalmic solutions which are dissolved before use
Proceed as directed in Aqueous Ophthalmic Solutions after dissolving the sample with the constituted solution.

3.3. Suspension type ophthalmic solutions
Proceed as directed in Aqueous Ophthalmic Solutions.
Take 25 mL of the sample in a vessel, which has been rinsed well with water for particulate matter test, add a suitable amount of a suspension-solubilizing solvent or an adequate solvent, shake to dissolve the suspending particles, and use this solution as the sample solution. Use a membrane filter which is not affected by the solvent to be used.

3.4. Ophthalmic solutions contained in a single-dose container

Proceed as directed in Aqueous Ophthalmic Solutions, using 10 samples for the test. A 13-mm diameter membrane filter and a 4-mm diameter filter holder for retaining insoluble particulate matter are used.

4. Evaluation

The preparation complies with the test if the calculated number per mL of insoluble particles of a size equal to or greater than 300 μm is not more than 1.

6.09 Disintegration Test

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopeia. The parts of the text that are not harmonized are marked with symbols (* •).

Disintegration Test is provided to determine whether tablets, capsules, granules, dry syrups or pills, disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below.

For the purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent.

1. Apparatus

The apparatus consists of a basket-rack assembly, a 1000-mL, low-form beaker, 138 to 160 mm in height and having an inside diameter of 97 to 115 mm for the immersion fluid, a thermostatic arrangement for heating the fluid between 35° and 39°, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per minute through a distance of not less than 53 mm and not more than 57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid and descends to not less than 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition, rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

(i) Basket-rack assembly: The basket-rack assembly consists of six open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 20.7 ± 2.8 mm and a wall 1.0 ± 2.8 mm thick; the tubes are held in a vertical position by two plates, each 88 ± 2.6 mm in diameter and 5 to 8.5 mm in thickness, with six holes, each 22.5 to 26 mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the under surface of the lower plate is a woven stainless steel wire cloth, which has a plain square weave with 1.8- to 2.2-mm apertures and with a wire diameter of 0.57 to 0.66 mm. The parts of the apparatus are assembled and rigidly held by means of three bolts passing through the two plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device using a point on its axis. The basket-rack assembly conforms to the dimensions found in Fig. 6.09-1. The design of the basket-rack assembly may be varied somewhat provided the specifications for the glass tubes and the screen mesh size are maintained: * for example, in order to secure the glass tubes and the upper and the lower plastic plates in position at the top or the bottom, an acid-resistant metal plate, 88 – 92 mm in diameter and 0.5 – 1 mm in thickness, having 6 perforations, each about 22 to 26 mm in diameter, may be used which coincide with those of the upper plastic plate and upper open ends of the glass tubes. •

(ii) Disks: The use of disks is permitted only where specified or allowed. Each tube is provided with a cylindrical disk 9.5 ± 0.15 mm thick and 20.7 ± 0.15 mm in diameter. The disk is made of a suitable, transparent plastic material having a specific gravity of between 1.18 and 1.20. Five parallel 2 ± 0.1 mm holes extend between the ends of the cylinder. One of the holes is centered on the cylindrical axis. The other holes are centered 6 ± 0.2 mm from the axis on imaginary lines perpendicular to the axis and parallel to each other. Four identical trapezoidal-shaped planes are cut into the wall of the cylinder, nearly perpendicular to the ends of the cylinder. The trapezoidal shape is symmetrical; its parallel sides coincide with the ends of the cylinder and are parallel to an imaginary line connecting the centers of two adjacent holes 6 mm from the cylindrical axis. The parallel side of the trapezoid on the bottom of the cylinder has a length of 1.6 ± 0.1 mm, and its bottom edges lie at a depth of 1.5 – 1.8 mm from the cylinder’s circumference. The parallel side of the trapezoid on the top of the cylinder has a length of 9.4 ± 0.2 mm, and its center lies at a depth of 2.6 ± 0.1 mm from the cylinder’s circumference. All surfaces of the disk are smooth. If the use of disks is specified, add a disk to each tube, and operate the apparatus as directed under Proce-
dure. The disks conform to dimensions found in Fig. 6.09-1. The use of automatic detection employing modified disks is permitted where the use of disks is specified or allowed. Such disks must comply with the requirements for density and dimension given in this chapter.

* (iii) Auxiliary tube: The auxiliary tube, as illustrated in Fig. 6.09-2, consists of a plastic tube D, 12 ± 0.2 mm in inside diameter, 17 ± 0.2 mm in outside diameter, 20 ± 1 mm in length, having both outside ends screw-cut, and two plastic rings A, each 12 ± 0.2 mm in inside diameter, 17 ± 0.2 mm in outside diameter, 2.5 - 4.5 mm in length, having one inside end screw-cut. Acid-resistant woven wire gauze having 0.42-mm openings and 0.29-mm wire diameter is placed in each plastic ring and the rings are attached by screws to each end of the plastic tube. The distance between two wire gauses is 20 ± 1 mm. A handle of an acid-resistant wire, 1 mm in diameter and 80 ± 5 mm in length, is attached to the mid portion of the plastic tube. The auxiliary tube is used for the test of granules and capsules containing enteric coated granules.

2. Procedure

2.1. Immediate-release preparations

In case of tablets, capsules * and pills (except for pills containing crude drugs), place 1 dosage unit in each of the six tubes of the basket, and if prescribed add a disk. * Unless otherwise specified, operate the apparatus, using water as the immersion fluid, maintained at 37 ± 2°C as the immersion fluid. * Unless otherwise specified, carry out the test for 20 minutes for capsules, 30 minutes for plain tablets, and 60 minutes for coated tablets and pills. * Lift the basket from the fluid, and observe the dosage units. * Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disks, if used, is a soft mass having no palpably firm core. * The test is met if all of the dosage units have disintegrated completely. If 1 or 2 dosage units fail to disintegrate, repeat the test on 12 additional dosage units. The test is met if not less than 16 of the total of 18 samples tested are disintegrated.

* For pills containing crude drugs, carry out the test for 60 minutes in the same manner, using 1st fluid for disintegration test as the immersion fluid. When any residue of the unit is observed, carry out the test successively for 60 minutes, using 2nd fluid for disintegration test.

* In case of granules and dry syrups, shake preparations on a No. 30 (500 µm) sieve as directed in Particle Size Distribution Test for Preparations <6.03>, transfer 0.10 g of the residue on the sieve to each of the 6 auxiliary tubes, secure the 6 tubes to the bottom of the basket tightly, and operate the apparatus, using water as the immersion fluid, maintained at 37 ± 2°C as the immersion fluid, unless otherwise specified. Observe the samples after 30 minutes of operation for plain granules and after 60 minutes for coated granules, unless otherwise specified. Complete disintegration is defined as that state in which any residue of the granules, except fragments of insoluble coating in the auxiliary tube, is a soft mass having no palpably firm core. The test is met if all of 6 samples in the auxiliary tubes have disintegrated completely. If 1 or 2 samples fail to disintegrate, repeat the test on 12 additional samples. The test is met if not less than 16 of the total of 18 samples tested are disintegrated.

2.2. Enteric coated preparations

Unless otherwise specified, perform the following two tests, (a) the test with 1st fluid for disintegration test and (b) the test with the 2nd fluid for disintegration test, separately.

2.2.1. Enteric coated tablets and capsules

(i) The test with 1st fluid for disintegration test: Carry out the test for 120 minutes, using 1st fluid for disintegration test according to the procedure described in immediate release preparations. Disintegration is defined as that state in which the tablet or capsule is broken or the enteric coating film is ruptured or broken. The test is met if none of six dosage units is disintegrated. If 1 or 2 dosage units are disintegrated, repeat the test on additional 12 dosage units. The test is met if not less than 16 of the total of 18 dosage units tested are not disintegrated.

(ii) The test with 2nd fluid for disintegration test: According to the procedure described in immediate-release preparations, carry out the test with new dosage units for 60 minutes, using 2nd fluid for disintegration test and determine if the test is met or not.

2.2.2. Enteric coated granules and capsules containing the enteric coated granules

Shake granules or contents taken out from capsules on a No. 30 (500 µm) sieve as directed in Particle Size Distribution Test for Preparations <6.03>, transfer 0.10 g of the residue on the sieve to each of the 6 auxiliary tubes, secure the 6 tubes to the bottom of the basket tightly, and operate the apparatus, using the 1st and 2nd fluids for disintegration test.

(i) The test with 1st fluid for disintegration test: According to the procedure described in immediate-release preparations, carry out the test for 60 minutes, using 1st fluid for disintegration test. The test is met if particles fallen from the openings of the wire gauze number not more than 15.

(ii) The test with 2nd fluid for disintegration test: According to the procedure described in immediate-release preparations, carry out the test with new samples for 30 minutes, using 2nd fluid for disintegration test and determine if test is met or not.
6.10 Dissolution Test

This test is harmonized with the European Pharmacopoeia and the U. S. Pharmacopoeia. The parts of the text that are not harmonized are marked with symbols (*) •.

Dissolution Test is provided to determine compliance with the dissolution requirements for dosage forms administered orally. *This test also aims at preventing significant bioinequivalence. • In this test, a dosage unit is defined as 1 tablet or 1 capsule or the amount specified equivalent to minimum dose.

1. Apparatus

1.1. Apparatus for Basket Method (Apparatus 1)

The assembly consists of the following: a vessel, which may be covered, made of glass or other inert, transparent material*; a motor; a drive shaft; and a cylindrical basket. The vessel is partially immersed in a suitable water bath of any convenient size or heated by a suitable device such as a heating jacket. The water bath or heating device permits holding the temperature inside the vessel at $37 \pm 0.5^\circ C$ during the test and keeping the bath fluid in constant, smooth motion. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smoothly rotating stirring element. Make the apparatus to permit observation of the specimen and stirring element during the test. The vessel is cylindrical, with a hemispherical bottom and a capacity of 1 liter. Its height is 160 mm to 210 mm and its inside diameter is 98 mm to 106 mm. Its sides are flanged at the top. Use a fitted cover to prevent escape of undissolved particles from the top of the vessel and rotates smoothly and without significant wobble that could affect the results. Adjust a speed-regulating device to maintain the shaft rotation speed at a specified rate, within $\pm 4\%$.

Shaft and basket components of the stirring element shown in Fig. 6.10-1 are fabricated of stainless steel (SUS316) or other inert material. A basket having a gold coating of about $0.0001$ inch (2.5 µm) thick may be used. The dosage unit is placed in a dry basket at the beginning of each test. The distance between the inside bottom of the vessel and the bottom of the basket is maintained at $25 \pm 2$ mm during the test.

1.2. Apparatus for Paddle Method (Apparatus 2)

Use the assembly from Apparatus 1, except that a paddle formed from a blade and a shaft is used as the stirring element. The paddle blade and shaft component of the stirring element is not more than 2 mm from the vertical axis of the vessel, at any point, and rotates smoothly without significant wobble that could affect the results. The vertical center line of the blade passes through the axis of the shaft so that the bottom of the blade is flush with the bottom of the shaft. The paddle conforms to the specifications shown in Fig. 6.10-2. The distance of $25 \pm 2$ mm between the bottom of the blade and the inside bottom of the vessel is maintained during the test. The metallic or suitably inert, rigid blade and shaft comprise a single entity. A suitable two-part detachable design may be used provided the assembly remains firmly engaged during the test. The paddle blade and shaft may be coated with a suitable coating so as to make them inert. The dosage unit is usually allowed to sink to the bottom of the vessel before rotation of the blade is started. A small, loose piece of non-reactive material, such as not more than a few turns of wire helix or such one shown in Fig. 6.10-2a, may be attached to the dosage unit that would otherwise float. Other validated sinker devices may also be used. •If the use of sinker is specified, unless otherwise specified, use the sinker device shown in Fig. 6.10-2a.

1.3. Apparatus for Flow-Through Cell Method (Apparatus 3)

The assembly consists of a reservoir and a pump for the dissolution medium; a flow-through cell; a water bath that maintains the dissolution medium at $37 \pm 0.5^\circ C$. Use the cell size specified in the individual monograph.

The pump forces the dissolution medium upwards through the flow-through cell. The pump has a delivery range between 4 and 16 mL per minute, with standard flow rates of 4, 8, and 16 mL per minute. It must deliver a constant flow ($\pm 5$ per cent of the nominal flow rate); the flow profile should be sinusoidal with a pulsation of 120 $\pm 10$ pulses per minute. A pump without the pulsation may also be used. Dissolution test procedure using the flow-through cell must be characterized with respect to flow rate and any pulsation.

Fig. 6.10-1 Apparatus 1, Basket stirring element
cone is usually filled with small glass beads of about 1-mm diameter with one bead of about 5-mm positioned at the apex to protect the fluid entry tube; a tablet holder (see Figures 6.10-3 and 6.10-4) is available for positioning of special dosage forms. The cell is immersed in a water bath, and the temperature is maintained at 37 ± 0.5°C.

The apparatus uses a clamp mechanism of two O-rings to assemble the cell. The pump is separated from the dissolution unit in order to shield the latter against any vibrations originating from the pump. The position of the pump should not be on a level higher than the reservoir flasks. Tube connections are as short as possible. Use suitably inert tubing, such as polytet, with about 1.6-mm inner diameter and inert flanged-end connections.

Notes:
(1) A and B dimensions are not to vary more than 0.5 mm when part is rotated on centering axis.
(2) Tolerances are ±1.0 mm unless otherwise stated.

Fig. 6.10-2 Apparatus 2, Paddle stirring element

Fig. 6.10-2a Alternative sinker

Fig. 6.10-3 Apparatus 3
Large cell for tablets and capsules (top); tablet holder for the large cell (bottom)
(All dimensions are expressed in mm unless otherwise noted.)

2. Apparatus Suitability
The determination of suitability of a test assembly to perform dissolution testing must include conformance to the dimensions and tolerances of the apparatus as given above. In addition, critical test parameters that have to be monitored periodically during use include volume and temperature of the dissolution medium, rotation speed (Basket Method and Paddle Method), and flow rate of medium (Flow-Through Cell Method).

Determine the acceptable performance of the dissolution test assembly periodically.

3. Procedure
3.1. Basket Method or Paddle Method
3.1.1. Immediate-release Dosage Forms
(i) Procedure: Place the stated volume of the dissolution medium (±1%) in the vessel of the specified apparatus, assemble the apparatus, equilibrate the dissolution medium to
JP XVI

General Tests / 6.10 Dissolution Test

37 ± 0.5°C, and remove the thermometer. Place 1 dosage unit in the apparatus, taking care to exclude air bubbles from the surface of the dosage unit, and immediately operate the apparatus at the specified rate. Within the time interval specified, or at each of the times stated, withdraw a specimen from a zone midway between the surface of the Dissolution Medium and the top of the rotating basket or blade, not less than 10 mm from the vessel wall.

[NOTE—Where multiple sampling times are specified, replace the aliquots withdrawn for analysis with equal volumes of fresh Dissolution Medium at 37°C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test, and verify the temperature of the mixture under test at suitable times.] Perform the analysis using an indicated assay method.*3 Repeat the test with additional dosage units.

If automated equipment is used for sampling or the apparatus is otherwise modified, verification that the modified apparatus will produce results equivalent to those obtained with the standard apparatus described in this chapter, is necessary.

(iii) Time: Where a single time specification is given, the test may be concluded in a shorter period if the requirement for minimum amount dissolved is met. Specimens are to be withdrawn only at the stated times, within a tolerance of ±2%.

3.1.2. Extended-release Dosage Forms

(i) Procedure: Proceed as described for Immediate-Release Dosage Forms.

(ii) Dissolution Medium: Proceed as directed under Immediate-Release Dosage Forms.

(iii) Time: The test-time points, generally three, are expressed in hours.

3.1.3. Delayed-release Dosage Forms

(i) Procedure: Unless otherwise specified, proceed the acid stage test and buffer stage test separately as described for Immediate-Release Dosage Forms.

(ii) Dissolution Medium: Acid stage: Unless 1st fluid for dissolution test is used, proceed as directed under Immediate-Release Dosage Forms. Buffer stage: Unless 2nd fluid for dissolution test is used, proceed as directed under Immediate-Release Dosage Forms.

(iii) Time: Acid stage: Generally, test time is 2 hours for tablets and capsules, and 1 hour for granules. Buffer stage: The same as directed under Immediate-Release Dosage Forms. All test times stated are to be observed within a tolerance of ±2%, unless otherwise specified.

3.2. Flow-Through Cell Method

3.2.1. Immediate-release Dosage Forms

(i) Procedure: Place the glass beads into the cell specified in the individual monograph. Place 1 dosage unit on top of the beads or, if specified, on a wire carrier. Assemble the filter head and fix the parts together by means of a suitable clamping device. Introduce by the pump the dissolution medium warmed to 37 ± 0.5°C through the bottom of the cell to obtain the flow rate specified and measured with an accuracy of 5%. Collect the eluate by fractions at each of the times stated. Perform the analysis as directed. Repeat the test with additional dosage units.

(ii) Dissolution Medium: Proceed as directed under Immediate-Release Dosage Forms under Basket Method and Paddle Method.

(iii) Time: Proceed as directed under Immediate-Release Dosage Forms under Basket Method and Paddle Method.

3.2.2. Extended-release Dosage Forms

(i) Procedure: Proceed as described for Immediate-Release Dosage Forms under Flow-Through Cell Method.

(ii) Dissolution Medium: Proceed as described for Immediate-Release under Flow-Through Cell Method.

(iii) Time: The test-time points, generally three, are expressed in hours.

4. Interpretation

4.1. Immediate-release Dosage Forms

*Follow Interpretation 1 when the value Q is specified in
the individual monograph, otherwise follow Interpretation 2.

4.1.1. Interpretation 1

Unless otherwise specified, the requirements are met if the quantities of active ingredient dissolved from the dosage units tested conform to Acceptance Table 6.10-1. Continue testing through the three stages unless the results conform at either S1 or S2. The quantity, expressed as a percentage of the labeled content, of active ingredient dissolved from the units tested conform to Acceptance Table 6.10-1. Continue testing through the three stages unless the results conform at A2.

4.1.2. Interpretation 2

Unless otherwise specified, perform the test on 6 dosage forms: if the individual dissolution rate meet the requirements specified in the individual monograph, the dosage forms conform to the test. When individual dissolution rates of 1 or 2 dosage forms fail to meet the requirements, repeat the test on another 6 dosage forms: if individual dissolution rates of not less than 10 dosage forms out of 12 meet the requirements, the dosage forms conform to the test.

4.2. Extended-release Dosage Forms

4.2.1. Interpretation 1

Unless otherwise specified, the requirements are met if the quantities of active ingredient dissolved from the dosage units tested conform to Acceptance Table 6.10-2. Continue testing through the three stages unless the results conform at either L1 or L2. Limits on the amounts of active ingredient dissolved are expressed in terms of the percentage of labeled content. The limits embrace each value of 

\[ Q \\]

\[ z \]

\[ 15 \]

\[ Q \]

\[ -15 \]

\[ z \]

\[ 25 \]

\[ z \]

\[ Q \]

\[ -25 \]

4.2.2. Interpretation 2

Unless otherwise specified, perform the test on 6 dosage forms: if the individual dissolution rate meet the requirements specified in the individual monograph, the dosage forms conform to the test. When individual dissolution rates of 1 or 2 dosage forms fail to meet the requirements, repeat the test on another 6 dosage forms: if individual dissolution rates of not less than 10 dosage forms out of 12 meet the requirements, the dosage forms conform to the test. Where more than one range is specified, the acceptance criteria apply individually to each range.

4.3. Delayed-release Dosage Forms

4.3.1. Interpretation 1

(i) Test using 1st fluid for dissolution test: Unless otherwise specified, the requirements of this portion of the test are met if the quantities, based on the percentage of the labeled content, of active ingredient dissolved from the units tested conform to Acceptance Table 6.10-3. Continue testing through the three levels unless the results conform at A2.

(ii) Test using 2nd fluid for dissolution test: Unless otherwise specified, the requirements are met if the quantities of active ingredient dissolved from the units tested con-
form to Acceptance Table 6.10-4. Continue testing through the three levels unless the results of both stages conform at an earlier level. The value of $Q$ in Acceptance Table 6.10-4 is the amount $^\ast$specified in monograph $^\ast$ of active ingredient dissolved, expressed as a percentage of the labeled content. The 5% and 15% and 25% values in Acceptance Table 6.10-4 are percentages of the labeled contest so that these values and $Q$ are in the same terms.

4.3.2. $^\ast$Interpretation 2

Unless otherwise specified, both the tests using 1st fluid for dissolution test and 2nd fluid for dissolution test in acid and buffer stages, perform the test on 6 dosage forms: if the individual dissolution rate meet the requirements specified in the individual monograph, the dosage forms conform to the test. When individual dissolution rates of 1 or 2 dosage forms fail to meet the requirements, repeat the test on another 6 dosage forms: if individual dissolution rates of not less than 10 dosage forms out of 12 meet the requirements, the dosage forms conform to the test.

$^\ast$The materials should not sorb, react, or interfere with the specimen being tested.

$^\ast$If a cover is used, it provides sufficient openings to allow ready insertion of the thermometer and withdrawal of specimens.

$^\ast$Test specimens are filtered immediately upon sampling unless filtration is demonstrated to be unnecessary. Use an inert filter that does not cause adsorption of the ingredient or contain extractable substances that would interfere with the analysis.

$^\ast$One method of deaeration is as follows: Heat the medium, while stirring gently, to about 41°C, immediately filter under vacuum using a filter having a porosity of 0.45 $\mu$m or less, with vigorous stirring, and continue stirring under vacuum for about 5 minutes. Other validated deaeration techniques for removal of dissolved gases may be used.

6.11 Foreign Insoluble Matter Test for Ophthalmic Solutions

Foreign Insoluble Matter Test for Ophthalmic Solutions is a test method to examine foreign insoluble matters in ophthalmic solutions.

When inspect with the unaided eyes at a position of luminous intensity of 3000 – 5000 lx under an incandescent lamp after cleaning the exterior of containers, Ophthalmic Solutions must be clear and free from readily detectable foreign insoluble matters.

7. Tests for Containers and Packing Materials

7.01 Test for Glass Containers for Injections

The glass containers for injections do not interact physically or chemically with the contained medicament to alter any property or quality, can protect the contained medicament from the invasion of microbes by means of perfect sealing or other suitable process, and meet the following requirements. The surface-treated container for aqueous infusion is made from glass which meets the requirements for the soluble alkali test for a container not to be fused under method 1.

(1) The containers are colorless or light brown and transparent, and have no bubbles which interfere the test of the Foreign Insoluble Matter Test for Injections $<6.06>$.

(2) Multiple-dose containers are closed by rubber stoppers or any other suitable stoppers. The stoppers permit penetration of an injection needle without detachment of fragments, and upon withdrawal of the needle, they reclose the containers immediately to prevent external contamination, and also do not interact physically or chemically with the contained medicaments.

Containers intended for aqueous infusions are closed by rubber stoppers meeting the requirements of the test for Rubber Closure for Aqueous Infusions $<7.07>$.

(3) Soluble alkali test—The testing methods may be divided into the following two methods according to the type of container or the dosage form of the medicament.

(i) Method 1: This method is applied to containers to be fused, or containers not to be fused except containers for aqueous infusions with a capacity exceeding 100 mL.

Rinse thoroughly the inside and outside of the containers to be tested with water, dry, and roughly crush, if necessary. Transfer 30 to 40 g of the glass to a steel mortar, and crush. Sieve the crushed glass through a No. 12 (1400 $\mu$m) sieve. Transfer the portion retained on the sieve to the steel mortar, and repeat this crushing procedure until 2/3 of the amount of powdered glass has passed through a No. 12 (1400 $\mu$m) sieve. Combine all portions of the glass powder passed through a No. 12 (1400 $\mu$m) sieve, shake the sieve in a horizontal direction for 5 minutes with slight tapping at intervals using No. 18 (850 $\mu$m) and No. 50 (300 $\mu$m) sieves. Transfer 7 g of the powder, which has passed through a No. 18 (850 $\mu$m) sieve but not through a No. 50 (300 $\mu$m) sieve to a No. 50 (300 $\mu$m) sieve, immerse it in a suitable container filled with water, and wash the contents with gentle shaking for 1 minute. Rinse again with ethanol (95%) for 1 minute, dry the washed glass powder at 100°C for 30 minutes, and allow to cool in a desiccator (silica gel). Transfer exactly 5.0 g of the powder thus prepared to a 200-mL conical flask of hard glass, add 50 mL of water, and gently shake the flask so that the powder disperses on the bottom of the flask evenly. Cover the flask with a small beaker of hard glass or a watch glass of hard glass, then heat it in boiling water for 2 hours, and immediately cool to room temperature. Decant the water from the flask into a 250-mL conical flask of hard glass, wash well the residual powdered glass with three 20-mL portions of water, and add the washings to the decanted water. Add 5 drops of bromocresol green-methyl red TS and titrate $<2.30>$ with 0.01 mol/L sulfuric acid VS until the color of the solution changes from green through slightly grayish blue to slightly grayish red-purple. Perform a blank determination in the same manner, and make any necessary correction.

The quantity of 0.01 mol/L sulfuric acid VS consumed does not exceed the following quantity, according to the type of containers.

Containers to be fused 0.30 mL
Containers not to be fused (including injection
(ii) Method 2: This method is applied to containers not to be fused for aqueous infusions with a capacity exceeding 100 mL.

Rinse thoroughly the inside and outside of the containers to be tested with water, and dry. Add a volume of water equivalent to 90% of the overflow capacity of the container, cover it with a small beaker of hard glass or close tightly with a suitable stopper, heat in an autoclave at 121°C for 1 hour, and allow to stand until the temperature falls to room temperature, measure exactly 100 mL of the this solution, and transfer to a 250-mL conical flask of hard glass. Add 5 drops of bromocresol green-methyl red TS, and titrate ≤2.50 mL with 0.01 mol/L sulfuric acid VS until the color of the solution changes from green through slightly grayish blue to slightly grayish red-purple. Measure accurately 100 mL of water, transfer to a 250-mL conical flask of hard glass, perform a blank determination in the same manner, and make any necessary correction. The quantity of 0.01 mol/L sulfuric acid VS consumed does not exceed 0.10 mL.

(4) Soluble iron test for light-resistant containers—Rinse thoroughly five or more light-resistant containers to be tested with water, and dry at 105°C for 30 minutes. Pour a volume of 0.01 mol/L hydrochloric acid VS corresponding to the labeled volume of the container into individual containers, and fuse them. In the case of containers not to be fused, cover them with small beakers of hard glass or watch glasses of hard glass. Heat them at 105°C for 1 hour. After cooling, prepare the test solution with 40 mL of this solution according to Method 1 of the Iron Limit Test <1.10>, and perform the test according to Method B. Prepare the control solution with 2.0 mL of the Standard Iron Solution.

(5) Light transmission test for light-resistant containers—Cut five light-resistant containers to be tested, prepare test pieces with surfaces as flat as possible, and clean the surfaces. Fix a test piece in a cell-holder of a spectrophotometer to allow the light pass through the center of the test piece perpendicularly to its surface. Measure the light transmittance of the test piece with reference to air between 290 nm and 610 nm at intervals of 20 nm each. The percent transmissions obtained between 590 nm and 610 nm are not less than 45%, and that between 290 nm and 450 nm are not more than 50%.

7.02 Test Methods for Plastic Containers

Test methods for plastic containers may be used for designing and assuring quality of plastic containers. Not all tests described here will be necessary in any phases for any containers. On the other hand, the set does not include sufficient numbers and kinds of tests needed for any design verification and quality assurance of any containers. Additional tests may be considered if necessary.

It is not allowable for plastic containers for the aqueous injections to interact with the pharmaceutical contained therein resulting in the deterioration of its efficacy, safety or stability, and to contaminate with microorganisms. They should meet the requirements prescribed in 2. Requirements for Plastic Containers for Aqueous Injections.

1. Test methods

1.1. Combustion tests

1.1.1. Residue on ignition

Weigh accurately about 5 g of cut pieces of the container and perform the test according to Residue on Ignition <2.44>.

1.1.2. Heavy metals

Place an appropriate amount of cut pieces of the container in a porcelain crucible, and perform the test according to Method 2 of Heavy Metals Limit Test <1.07>. Prepare the control solution with 2.0 mL of Standard Lead Solution.

1.1.3. Lead

1.1.3.1. Method 1

Place 2.0 g of cut pieces of a container in a crucible of platinum or quartz, moisten with 2 mL of sulfuric acid, heat slowly to dryness, then heat to combustion at between 450°C and 500°C. Repeat this procedure, if necessary. After cooling, moisten the residue with water, add 2 to 4 mL of hydrochloric acid, evaporate to dryness on a water bath, then add 1 to 5 mL of hydrochloric acid, and warm to dissolve. Then add 0.5 to 1 mL of a mixture of a solution of citric acid monohydrate (1 in 2) and hydrosulphuric acid (1:1), and add 0.5 to 1 mL of a warmed solution of ammonium acetate (2 in 5). Filter through a glass filter (G3) if insoluble matter remains. To the obtained filtrate add 10 mL of a solution of diammonium hydrogen citrate (1 in 4), 2 drops of bromothymol blue TS and ammonia TS until the color of the solution changes from yellow to green. Then add 10 mL of a solution of ammonium sulfate (2 in 5) and water to make 100 mL. Add 20 mL of a solution of sodium N,N-diethyl-dithiocarbamate trihydrate (1 in 20) to this solution, mix, allow to stand for a few minutes, then add 20.0 mL of 4-methyl-2-pentanone, and shake vigorously. Allow to stand to separate the 4-methyl-2-pentanone layer, filter if necessary, and use the layer as the sample solution. Separately, to 2.0 mL of Standard Lead Solution add water to make exactly 10 mL. To 1.0 mL of this solution add 10 mL of a solution of diammonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, then proceed in the same manner as for the sample solution, and use the solution so obtained as the standard solution. Perform the test with the sample solution and standard solution according to Atomic Absorption Spectrophotometry <2.23> under the following conditions, and determine the concentration of lead in the sample solution.

Gas: Combustible gas—Acetylene or hydrogen.
Supporting gas—Air.
Lamp: Lead hollow-cathode lamp.
Wavelength: 283.3 nm.

1.1.3.2. Method 2

Cut a container into pieces smaller than 5-mm square, take 2.0 g of the pieces into a glass beaker, add 50 mL of 2-butanol and 0.1 mL of nitric acid, and warm to dissolve. To this solution add 96 mL of methanol gradually to precipitate a resinous substance, and filter by suction. Wash the beaker and the resinous substance with 12 mL of methanol followed by 12 mL of water, combine the washings and the filtrate, and concentrate to about 10 mL under reduced pressure. Transfer into a separator, add 10 mL of ethyl acetate
and 10 mL of water, shake vigorously, and allow to stand to separate the water layer. Evaporate the water layer to dryness, add 5 mL of hydrochloric acid to the residue, and warm to dissolve. Then add 1 mL of a mixture of a solution of citric acid monohydrate (1 in 2) and hydrochloric acid (1:1), and add 1 mL of a warmed solution of ammonium acetate gently heating in a 500 mL beaker (3). Filter through a glass filter (G3) if insoluble matter remains. To the solution so obtained add 10 mL of a solution of diaminonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, and then add ammonia TS until the color of the solution changes from yellow to green. Further add 10 mL of a solution of ammonium sulfate (2 in 5) and water to make 100 mL. Add 20 mL of a solution of sodium N,N-diethylthiophosphate trihydrate (1 in 20) to this solution, mix, allow to stand for a few minutes, then add 20.0 mL of 4-methyl-2-pentanone, and shake vigorously. Allow to stand to separate the 4-methyl-2-pentanone layer, filter the layer if necessary, and use the layer as the sample solution. Separately, pipet 5 mL of Standard Lead Solution, add water to make exactly 50 mL, and add 2.0 mL of this solution add 10 mL of a solution of diaminonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, then proceed in the same manner as for the sample solution, and use the solution so obtained as the standard solution. Perform the test with the sample solution and standard solution according to Atomic Adsorption Spectrophotometry \( \text{C2.2.25} \) under the conditions described in Method 1, and determine the concentration of lead in the sample solution.

### 1.1.4. Cadmium

#### 1.1.4.1. Method 1

To 2.0 mL of Standard Cadmium Solution add 10 mL of a solution of diaminonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, and proceed in the same manner as for the sample solution in “1.1.3.1. Method 1”, and use the solution so obtained as the standard solution. Perform the test with the sample solution obtained in “1.1.3.1. Method 1” and the standard solution according to Atomic Adsorption Spectrophotometry \( \text{C2.2.25} \) under the following conditions, and determine the concentration of cadmium in the sample solution.

Gas: Combustible gas—Acetylene or hydrogen.

Supporting gas—Air.

Lamp: Cadmium hollow-cathode lamp.

Wavelength: 228.8 nm.

#### 1.1.4.2. Method 2

To 2.0 mL of Standard Cadmium Solution add 10 mL of a solution of diaminonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, and proceed in the same manner as for the sample solution in “1.1.3.2. Method 2”, and use the solution so obtained as the standard solution. Perform the test with the sample solution obtained in “1.1.3.2. Method 2” and the standard solution according to Atomic Adsorption Spectrophotometry \( \text{C2.2.25} \) under the conditions described in “1.1.4.1. Method 1”, and determine the concentration of cadmium in the sample solution.

### 1.1.5. Tin

Cut a container into pieces smaller than 5-mm square, place 5.0 g of pieces in a Kjeldahl flask, add 30 mL of a mixture of sulfuric acid and nitric acid (1:1), and decompose by gentle heating in a muffle furnace, occasionally adding dropwise a mixture of sulfuric acid and nitric acid (1:1) until the content changes to a clear, light brown solution. Then heat until the color of the solution changes to a clear, light yellow, and heat to slowly concentrate to practical dryness. After cooling, dissolve the residue in 5 mL of hydrochloric acid by warming, and after cooling, add water to make exactly 10 mL. Pipet 5 mL of this solution into a 25-mL volumetric flask (A). Transfer the remaining solution to a 25-mL beaker (B) by washing out with 10 mL of water, add 2 drops of bromocresol green TS, neutralize with diluted ammonia solution (28) (1 in 2), and measure the volume consumed for neutralization as a mL. To the volumetric flask, A, add potassium permanganate TS dropwise until a slight pale red color develops, and add a small amount of l-ascorbic acid to decolorize. Add 1.5 mL of 1 mol/L hydrochloric acid TS, 5 mL of a solution of citric acid monohydrate (1 in 10), a mL of diluted ammonia solution (28) (1 in 2), 2.5 mL of polyvinyl alcohol TS, 5.0 mL of phenylfluorone-ethanol TS and water to make 25 mL. Shake well, then allow to stand for about 20 minutes, and use this solution as the sample solution. Separately, pipet 1.0 mL of Standard Tin Solution, add 5 mL of water, add potassium permanganate TS dropwise until a slight pale red color develops, proceed in the same manner as for the sample solution, and use this solution as the standard solution. Determine the absorbances of the sample solution and the standard solution according to Ultraviolet-visible Spectrophotometry \( \text{C2.2.4} \) at 510 nm, using water as the blank.

### 1.2. Extractable substances

Cut the container at homogeneous regions of low curvature and preferably the same thickness, gather pieces to make a total surface area of about 1200 cm² when the thickness is 0.5 mm or less, or about 600 cm² when the thickness is greater than 0.5 mm, and subdivide in general into strips approximately 0.5 cm in width and 5 cm in length. Wash them with water, and dry at room temperature. Place these strips in a 300-mL hard glass vessel, add exactly 200 mL of water, and seal the opening with a suitable stopper. After heating the vessel in an autoclave at 121°C for 1 hour, take out the vessel, allow to stand until the temperature falls to room temperature, and use the content as the test solution.

For containers made of composite plastics, the extraction may be performed by filling a labeled volume of water in the container. In this case, it is necessary to record the volume of water used and the inside area of the container.

When containers are deformed at 121°C, the extraction may be performed at the highest temperature which does not cause deformation among the following conditions: at 100 ± 2°C for 2 ± 0.2 hours, at 70 ± 2°C for 24 ± 2 hours, at 50 ± 2°C for 72 ± 2 hours or at 37 ± 1°C for 72 ± 2 hours.

Prepare the blank solution with water in the same manner. For containers made of composite plastics, water is used as the blank solution.

Perform the following tests with the test solution and the blank solution:

(i) Foaming test: Place 5 mL of the test solution in a glass-stoppered test tube about 15 mm in inside diameter and about 200 mm in length, shake vigorously for 3 minutes, and measure the time needed for almost complete disappearance of the foam thus generated.

(ii) pH \( \text{C2.5.4} \): To 20 mL each of the test solution and the blank solution add 1.0 mL of a solution of potassium chloride (1 in 1000), and obtain the difference in the reading of pH between these solutions.

(iii) Potassium permanganate-reducing substances: Place
20.0 mL of the test solution in a glass-stoppered, conical flask, add 20.0 mL of 0.002 mol/L potassium permanganate VS and 1 mL of dilute sulfuric acid, and boil for 3 minutes. After cooling, add 0.10 g of potassium iodide, stopper tightly, shake, then allow to stand for 10 minutes, and titrate \(<?50\)` with 0.01 mol/L sodium thiosulfate VS (indicator: 5 drops of starch TS). Perform the test in the same manner, using 20.0 mL of the blank solution, and obtain the difference of the consumption of 0.002 mol/L potassium permanganate VS between these solutions.

(iv) UV spectrum: Read the maximum absorbances between 220 nm and 240 nm and between 241 nm and 350 nm of the test solution against the blank solution as directed under Ultraviolet-visible Spectrophotometry \(<?2.24\).

(v) Residue on evaporation: Evaporate 20 mL of the test solution on a water bath to dryness, and weigh the residue after drying at 105°C for 1 hour.

1.3. Test for fine particles
1.3.1. Test procedure
Rinse thoroughly the inside and outside of containers to be tested with water for particle matter test, fill the container with the labeled volume of water for particulate matter test or 0.9 w/v% sodium chloride solution, adjust the amount of air in the container to about 50 mL per 500 mL of the labeled volume, put tight stopper to the container, and heat it at 121°C for 25 minutes in an autoclave. After allowing to cool for 2 hours, take out the container from the autoclave, and then allow to stand at ordinary temperature for about 24 hours. If the containers are deformed at 121°C, employ a suitable temperature-time combination as directed under 1.2. Extractable substances. Clean the outside of the container, mix by turning upside-down 5 or 6 times, insert immediately a clean needle of filterless infusion set into the container through the rubber closure of the container, take the effluent from the container while mixing gently in a clean container for measurement, and use it as the test solution.

Counting of the fine particles must be performed in dustless, clean facilities or apparatus, using a light-shielded automatic fine particle counter. The sensor of the counter to be used must be able to count fine particles of 1.5 μm or more in diameter. The volume to be measured is 10 mL. Adjust the counter before measurement. For calibration of the diameter and number of particles, the standard particles for calibration of the light-shielded automatic fine particle counter should be used in suspension in water for particulate matter test or 0.9 w/v% sodium chloride solution.

Count five times the numbers of particles with diameters of 5 – 10 μm, 10 – 25 μm and more than 25 μm while stirring the test solution, and calculate the average particle numbers of four counts, excluding the first, as the number of particles in 1.0 mL of the test solution.

1.3.2. Reagent
Water for particulate matter test and 0.9 w/v% sodium chloride solution to be used for the tests should not contain more than 0.5 particles of 5 – 10 μm in size per 1.0 mL.

1.4. Transparency test
1.4.1. Method 1
This method can only be applied to containers which have a smooth and not embossed surface and rather low curvature. Cut the container at homogeneous regions of low curvature and preferably the same thickness to make 5 pieces of about 0.9 × 4 cm in size, immerse each piece in water filled in a cell for determination of the ultraviolet spectrum, and determine the transmittance at 450 nm as directed under Ultraviolet-visible Spectrophotometry \(<?2.24\) using a cell filled with water as a blank.

1.4.2. Method 2
Sensory test—This method can be applied to containers which have a rough or embossed surface. It can also be applied to testing of the transparency of containers in case where the turbidity of their pharmaceutical contents must be checked.

1.4.2.1. Test solutions
(i) Formadin standard suspension: To 15 mL of the formadin stock suspension add water to make 1000 mL. Use within 24 hours of preparation. Shake thoroughly before use.

(ii) Reference suspension: To 50 mL of Formadin standard suspension add water to make 100 mL.

1.4.2.2. Test procedures
(i) Method 2A (with control): Take two of containers to be tested, and fill one of them with the labeled volume of the reference suspension and the other with the same volume of water. Show these two containers to five subjects, separately, ask which one seems to be more turbid, and calculate the rate of correct answers.

(ii) Method 2B (without control): Take six of containers to be tested, put number to each of them, and fill three of them with the labeled volume of the reference suspension and the others with the same volume of water. Show each one of these containers at random order to five subjects, separately, ask if it is turbid or not, and calculate the percentage of the answer judged as “turbid” (100 X/15, X: number of containers judged as “turbid”) for reference suspension-filled containers group and water-filled containers group, respectively.

1.5. Water vapor permeability test
1.5.1. Method 1
This test method is applicable to containers for aqueous injection. Fill the container with the labeled volume of water. After closing it hermetically, accurately weigh the container and record the value. Store the container at 65 ± 5% relative humidity and a temperature of 20 ± 2°C for 14 days, and then accurately weigh the container again and record the value. Calculate the mass loss during storage.

1.5.2. Method 2
This test method is provided for evaluating moisture permeability of containers for hygroscopic drugs. Unless otherwise specified, perform the test according to the following procedure.

1.5.2.1. Desiccant
Place a quantity of calcium chloride for water determination in a shallow container, taking care to exclude any fine powder, then dry at 110°C for 1 hour, and cool in a desiccator.

1.5.2.2. Procedure
Select 12 containers, clean their surfaces with a dry cloth, and close and open each container 30 times in the same manner. Ten among the 12 containers are used as “test containers” and the remaining two, as “control containers”. A torque for closing screw-capped containers is specified in Table 7.02-1. Add desiccant to 10 of the containers, designated test containers, filling each to within 13 mm of the closure if the container volume is 20 mL or more, or filling each to two-thirds of capacity if the container volume is less than 20 mL. If the interior of the container is more than 63

mm in depth, an inert filler or spacer may be placed in the bottom to minimize the total mass of the container and desiccant; the layer of desiccant in such a container shall be not less than 5 cm in depth. Close each container immediately after adding desiccant, applying the torque designated in the table. To each of the control containers, add a sufficient number of glass beads to attain a mass approximately equal to that of each of the test containers, and close, applying the torque designated in the table. Record the mass of the individual containers so prepared to the nearest 0.1 mg if the container volume is less than 20 mL, to the nearest 1 mg if the container volume is 20 mL or more but less than 200 mL, or to the nearest 10 mg if the container volume is 200 mL or more, and store the containers at 75 ± 3% relative humidity and a temperature of 20 ± 2°C. After 14 days, record the mass of the individual containers in the same manner. Completely fill 5 empty containers with water or a non-compressible, free-flowing solid such as fine glass beads, to the level indicated by the closure surface when in place. Transfer the contents of each to a graduated cylinder, and determine the average container volume, in mL. Calculate the rate of moisture permeability, in mg per day per liter, by use of the formula:

\[
\frac{(1000/14 \cdot V) \cdot (T_i - T_f) - (C_i - C_f)}{C_i - C_f}
\]

\(V\): average volume (mL)

\(T_i - T_f\): difference between the final and initial masses of each test container (mg)

\(C_i - C_f\): average of the differences between the final and initial masses of the two controls (mg)

### 1.6. Leakage test

Fill a container with a solution of fluorescein sodium (1 in 1000), stopper tightly, place filter papers on and under the container, and apply a pressure of 6.9 N (0.7 kg)/cm² at 20°C for 10 minutes. Judge the leakiness by observing the color of the paper.

### 1.7. Cytotoxicity test

The following test methods are designed to detect cytotoxic substances in plastic materials by evaluating the cytotoxicity of the culture medium extracts from plastic containers for pharmaceutical products. Other appropriate standard methods of cytotoxicity testing may be used for the evaluation, if appropriate. However, the final decision shall be made based upon the test methods given here, if the test results obtained according to the other methods are questionable.

#### 1.7.1. Cell lines

The recommended cell lines are L929 (American Type Culture Collection-ATCC CCL1) and V79 (Health Science Research Resources Bank-JCRB0603). In addition, other established cell lines may be used when it is confirmed that they form well-defined colonies reproducibly, with characteristics comparable to those of L929 and V79 cells.

#### 1.7.2. Culture medium

Eagle’s minimum essential medium prepared as follows shall be used. Dissolve the chemicals listed below in 1000 mL of water. Sterilize the solution by autoclaving at 121°C for 20 minutes. Cool the solution to room temperature, and add 22 mL of sterilized sodium hydrogen carbonate TS and 10 mL of sterilized glutamine TS. To the resultant solution add fetal calf serum (FCS) to make 10 vol% FCS in the medium.

- sodium chloride 6.80 g
- potassium chloride 400 mg
- sodium dihydrogen phosphate (anhydrous) 115 mg
- magnesium sulfate (anhydrous) 93.5 mg
- calcium chloride (anhydrous) 200 mg
- glucose 1.00 g
- L-arginine hydrochloride 126 mg
- L-cysteine hydrochloride monohydrate 31.4 mg
- L-tyrosine 36.0 mg
- L-histidine hydrochloride monohydrate 42.0 mg
- L-isoleucine 52.0 mg
- L-leucine 52.0 mg
- L-lysine hydrochloride 73.0 mg
- L-methionine 15.0 mg
- L-phenylalanine 32.0 mg
- L-threonine 48.0 mg
- L-tryptophan 10.0 mg
- L-valine 46.0 mg
- succinic acid 75.0 mg
- succinic acid hexahydrate 100 mg
- choline bitartrate 1.8 mg
- folic acid 1.0 mg
- myo-inositol 2.0 mg
- nicotinamide 1.0 mg
- calcium D-pantothenate 1.0 mg
- pyridoxal hydrochloride 1.0 mg
- riboflavin 0.1 mg
- thiamine hydrochloride 1.0 mg
- biotin 0.02 mg
- phenol red 6.0 mg

#### 1.7.3. Reagents

1. Sodium hydroxide carbonate TS: Dissolve 10 g of sodium hydroxide carbonate in water to make 100 mL. Sterilize the solution either by autoclaving in a well-sealed container at 121°C for 20 minutes or by filtration through a membrane filter with a nominal pore diameter of 0.22 μm or less.
1.7.5. Control materials and substances

(i) Glutamine TS: Dissolve 2.92 g of L-glutamine in water to make 100 mL. Sterilize the solution by passing it through a membrane filter of pore size equal to or less than 0.22 μm.

(ii) Phosphate buffer solution (PBS): Dissolve 0.20 g of potassium chloride, 0.20 g of potassium dihydrogenphosphate, 8.00 g of sodium chloride, and 1.15 g of disodium hydrogenphosphate (anhydrous) in water to make 1000 mL. Sterilize the solution by autoclaving at 121°C for 20 minutes.

(iii) Trypsin TS: Dissolve 0.5 g of trypsin and 0.2 g of disodium dihydrogen ethylenediamine tetraacetate dihydrate in phosphate buffer solution to make 100 mL. Sterilize the solution by passing it through a membrane filter of pore size equal to or less than 0.22 μm.

(iv) Formaldehyde solution: Dilute formaldehyde solution with water by a factor of ten.

(v) Giemsa’s stain solution: Dilute a commercially available Giemsa’s test solution with the diluent by a factor of fifty. Prepare before use.

(vi) Diluent: Dissolve 4.54 g of potassium dihydrogenphosphate and 4.75 g of disodium hydrogen phosphate (anhydrous) in water to make 1000 mL.

1.7.4. Devices and instruments

(i) Pipets: Pasteur pipet, pipet for partial delivery, measuring pipet for partial delivery, and dispenser with micropipet.

(ii) Screw-capped glass bottles: 50 – 1000 mL volume.

(iii) Sterile disposable centrifuge tubes: 15 and 50 mL volume.

(iv) Sterile disposable tissue culture flasks with a flat bottom surface of the well. Discard the supernatant, resuspend the cells in an appropriate volume of fresh culture medium and gently pipet the cells completely out of the flask by using a Pasteur pipet. Transfer the pipetted cell suspension into a sterile disposable centrifuge tube and centrifuge the tube at 800 – 1000 revolutions per minute for 2 – 5 minutes. Discard the supernatant, resuspend the cells in an appropriate volume of fresh culture medium to the flask. Resuspend the cells by pipetting and make a single cell suspension. Determine the cell concentration using a hemocytometer.

(v) Cytotoxicity testing: Dilute the cell suspension prepared according to procedure (iii) with culture medium to 100 cells/mL. Place a 0.5 mL aliquot of the diluted cell suspension on each well of a sterile disposable multiple well plate. Incubate the plate in the humidified incubator for 4 – 6 hours to attach the cells to the bottom surface of the well. Discard the medium from each well, and add a 0.5 mL aliquot of the test solution or fresh medium to quadruplicate wells. Place the plate immediately in the humidified incubator and incubate the plate for the appropriate period: 7 – 9 days for L929 cells; 6 – 7 days for V79 cells. After the incubation, discard the medium from the plate, and add an appropriate volume of dilute formaldehyde TS to each well and allow the plate to stand for 30 minutes to fix the cells. Discard the dilute formaldehyde TS from each well and add an appropriate volume of dilute Giemsa’s TS to each well. After ensuring good staining of the colonies, discard the stain solution from the wells and count the number of colonies in each well. Calculate a mean number of colonies for each concentration of the test solution, and divide the mean by the mean number of colonies for the fresh medium to obtain the colony formation rate (%) for each extract concentration of the test solution. Plot the extract concentration (%) of the test solution on a logarithmic scale and the colony formation rate on an ordinary scale on semilogarithmic graph paper to obtain a colony formation inhibition curve of the container. Read the % extract concentration which inhibits colony formation to 50%, IC50 (%), from the inhibition curve. It is recommended to check the sensitivity and the reproducibility of the test system by the use of suitable control materials or substances in the test system, if necessary.
2. Requirements for Plastic Containers for Aqueous Injections

2.1. Polyethylene or polypropylene containers for aqueous injections

The containers are made of polyethylene or polypropylene and free from any adhesive.

(1) Transparency—The containers have a transmittance of not less than 55%, when tested as directed in “1.4.1. Method 1”. When “1.4.1. Method 1” can not be applied, test according to “1.4.2.2. (ii) Method 2B”. In this case, the rate that the water-containing container is judged as “being turbid” is not more than 20%, and the rate that the reference suspension-containing container is judged as “being turbid” is not less than 80%.

(2) Appearance—The containers do not have strips, cracks, bubbles, or other faults which cause difficulties in practical use.

(3) Water vapor permeability—Proceed as directed in “1.5.1. Method 1”. The loss of mass is not more than 0.20%.

(4) Heavy metals $\langle 0.07 \rangle$—The turbidity of the test solution is not greater than that of the control solution when the amount of the sample taken is 1.0 g.

(5) Lead—Perform the test as directed in “1.1.3.1. Method 1”. The absorbance of the sample solution is not more than that of the standard solution.

(6) Cadmium—Perform the test as directed in “1.1.4.1. Method 1”. The absorbance of the sample solution is not more than that of the standard solution.

(7) Residue on ignition $\langle 2.40 \rangle$—Not more than 0.1% (5 g).

(8) Extractable substances—
   (i) Foaming test: the foam formed almost disappears within 3 minutes.
   (ii) pH: the difference in the reading of pH between the test solution and the blank solution is not more than 1.5.
   (iii) Potassium permanganate-reducing substances: The difference in the consumption of 0.002 mol/L potassium permanganate VS between the test solution and the blank solution is not more than 1.0 mL.
   (iv) UV spectrum: The maximum absorbance between 220 nm and 240 nm is not more than 0.08, and that between 241 nm and 350 nm is not more than 0.05.
   (v) Residue on evaporation: Not more than 1.0 mg.

(9) Cytotoxicity—IC$_{50}$ (%) is not less than 90%. The result obtained by the other standard methods is negative.

2.2. Polyvinyl chloride containers for aqueous injections

The containers are composed of homopolymer of vinyl chloride, free from any adhesive, and the plasticizer added to the material should be di(2-ethylhexyl)phthalate. The containers may be covered with easily removable material to prevent the permeation of water vapor. In this case, perform the water vapor permeability test on the covered containers.

(1) Thickness—Measure the thickness of a container at five different locations. The difference between the maximum and minimum values of thickness is 0.05 mm or less.

(2) Transparency—Proceed as directed in (1) under “2.1. Polyethylene or polypropylene containers for aqueous injections”.

(3) Appearance—Proceed as directed in (2) under “2.1. Polyethylene or polypropylene containers for aqueous injections”.

(4) Leakage—Proceed with the test according to “1.6. Leakage test”. The solution contained does not leak.

(5) Flexibility—Insert the spike needle for infusion through a rubber closure of the container used in (4) Leakage. The contained solution is almost completely discharged without displacement by air.

(6) Water vapor permeability—Proceed as directed in (3) under “2.1. Polyethylene or polypropylene containers for aqueous injections”.

(7) Heavy metals $\langle 1.07 \rangle$—The turbidity of the test solution is not greater than that of the control solution when the amount of the sample taken is 1.0 g.

(8) Lead—Perform the test as directed in “1.1.3.2. Method 2”. The absorbance of the sample solution is not more than that of the standard solution.

(9) Cadmium—Perform the test as directed in “1.1.4.2. Method 2”. The absorbance of the sample solution is not more than that of the standard solution.

(10) Tin—The absorbance of the sample solution is not more than that of the standard solution.

(11) Vinyl chloride—Wash cut pieces of a container with water, wipe them thoroughly with a filter paper, subdivide them into pieces smaller than 5 mm square, and put 0.5 g of them into a 20-mL vial. Add 2.5 mL of N,N-dimethylacetamide to the vial to dissolve the sample pieces, put a tight stopper on the vial, and use the solution in the vial as the sample solution. If the sample is hardly soluble, allow to stand the vial at room temperature for a night, put a tight stopper on the vial, and use the liquid part in the vial as the sample solution. Separately, to a 20-mL vial add 2.5 mL of N,N-dimethylacetamide, add 50 μL of Standard Vinyl Chloride Solution, previously cooled with dry ice-methanol, put a tight stopper on the vial, and use the solution in the vial as the sample solution.

After heating the vials containing sample solution and standard solution at 90°C for 1 hour, perform the test with 0.5 mL of each of vapor phases in these vials as directed under Gas Chromatography $\langle 2.02 \rangle$ according to the following conditions: the peak area of vinyl chloride obtained from the sample solution is not larger than that from the standard solution.

Operating conditions—

   Detector: A hydrogen flame-ionization detector.
   Column: A fused silica column 0.25 mm in inside diameter and 25 m in length, coated the inside surface in 3 μm thickness with porous styrene-divinylbenzene copolymer for gas chromatography.
   Column temperature: Maintain at 50°C for 2 minutes after injection, then rise to 120°C in the rate of 10°C per minute, then rise to 250°C in the rate of 20°C per minute, and keep at 250°C for 10 minutes.
   Injection port temperature: A constant temperature of about 200°C.
   Detector temperature: A constant temperature of about 250°C.
   Carrier gas: Nitrogen or helium.
   Flow rate: Adjust the flow rate so that the retention time of vinyl chloride is about 7 minutes.
   Split ratio: 1:5.

System suitability—

System performance: When the procedure is run under the above operating conditions with 0.5 mL of the vapor phase of the standard solution heated at 90°C for 1 hour, vinyl chloride and ethanol are eluted in this order with the resolu-
7.03 Test for Rubber Closure for Aqueous Infusions / General Tests

The rubber closure for aqueous infusions means a rubber closure (containing material coated or laminated with the stuff like plastics) used for a container for aqueous infusion having a capacity of 100 mL or more, and is in direct contact with the contained aqueous infusion. The rubber closure when in use does not interact physically or chemically with the contained medication to alter any property or quality, does not permit the invasion of microbes, does not disturb the use of the contained infusion, and meets the following requirements.

1. Cadmium

Wash the rubber closures with water, dry at room temperature, cut into minute pieces, mix well, place 2.0 g of them in 50 mL of sulfuric acid, heat gradually to dryness, and ignite between 450°C and 500°C until the residue is incinerated. When incineration was insufficient, moisten the residue with 1 mL of sulfuric acid, heat to dryness, and ignite again. Repeat the above-mentioned procedure if necessary. Cool the crucible, moisten the residue with water, add 2 to 4 mL of hydrochloric acid, heat on a water bath to dryness, add 1 to 5 mL of hydrochloric acid, and dissolve by heating. Then add 0.5 to 1 mL of a mixture of a solution of citric acid monohydrate (1 in 2) and hydrochloric acid (1:1) and 0.5 to 1 mL of a warmed solution of ammonium acetate (2 in 5). When any insoluble residue remains, filter through a glass filter. To the solution thus obtained add 10 mL of a solution of diammonium hydrogen citrate (1 in 4), 2 drops of bromothymol blue TS and ammonium TS until the color of the solution changes from yellow to green. Then add 10 mL of ammonium sulfate solution (2 in 5) and water to make 100 mL. Next, add 20 mL of a solution of sodium N,N-diethyldithiocarbamate trihydrate (1 in 20), mix, allow to stand for a few minutes, add 20.0 mL of 4-methyl-2-pentanone, and mix by vigorous shaking. Allow to stand to separate the 4-methyl-2-pentanone layer from the solution, filter if necessary, and use as the sample solution. On the other hand, to 10.0 mL of Standard Cadmium Solution add 10 mL of a solution of diammonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, proceed in the same manner as for the sample solution, and use this solution as the standard solution. Perform the tests according to the Atomic Absorption Spectrophotometry <2.23> under the following conditions, using the sample solution and the standard solution. The absorbance of the sample solution is not more than that of the standard solution.

Gas: Combustible gas—Acetylene or hydrogen.
Supporting gas—Air.
Lamp: Cadmium hollow-cathode lamp.
Wavelength: 228.8 nm.

2. Lead

To 1.0 mL of the Standard Lead Solution add 10 mL of a solution of diammonium hydrogen citrate (1 in 4) and 2 drops of bromothymol blue TS, proceed as directed for the sample solution under (1), and use this solution as the standard solution. Perform the tests according to the Atomic Absorption Spectrophotometry <2.23> under the following conditions, using the sample solution obtained in (1) and the standard solution. The absorbance of the sample solution is not more than that of the standard solution.

Gas: Combustible gas—Acetylene or hydrogen.
Supporting gas—Air.
Lamp: Lead hollow-cathode lamp.
Wavelength: 283.3 nm.

3. Extractable substances

Wash the rubber closures with water, and dry at room temperature. Place them in a glass container, add water exactly 10 times the mass of the test material, close with a suitable stopper, heat at 121°C for 1 hour in an autoclave, take out the glass container, allow to cool to room temperature, then take out immediately the rubber closures, and use the remaining solution as the test solution. Prepare the blank solution with water in the same manner. Perform the following tests with the test solution and the blank solution.

3.1. Description

The test solution is clear and colorless. Read the transparency of the test solution at 430 nm and 650 nm (10 mm), using the blank solution as the blank. Both of them are not less than 99.0%.

3.2. Foam test

Place 5 mL of the test solution in a glass-stoppered test tube of about 15 mm in inner diameter and about 200 mm in...
length, and shake vigorously for 3 minutes. The foam arisen disappears almost completely within 3 minutes.

3.3. pH <2.5>  
To 20 mL each of the test solution and the blank solution add 1.0 mL each of potassium chloride solution, prepared by dissolving 1.0 g of potassium chloride in water to make 1000 mL. The difference of pH between the two solutions is not more than 1.0.

3.4. Zinc  
To 10.0 mL of the test solution add diluted dilute nitric acid (1 in 3) to make 20 mL, and use this solution as the sample solution. Further, to 1.0 mL of Standard Zinc Solution for atomic absorption spectrophotometry add diluted nitric acid (1 in 3) to make exactly 20 mL, and use this solution as the standard solution. Perform the tests according to the Atomic Absorption Spectrophotometry <2.23>, using these solutions, under the following conditions. The absorbance of the sample solution is not more than that of the standard solution.

- Gas: Combustible gas—Acetylene.
- Supporting gas—Air.
- Lamp: Zinc hollow-cathode lamp.
- Wavelength: 213.9 nm.
- Standard Zinc Solution for atomic absorption spectrophotometry: Measure exactly 10 mL of the Standard Zinc Stock Solution, and add water to make exactly 1000 mL. Prepare before use. One mL of this solution contains 0.01 mg of zinc (Zn).

3.5. Potassium Permanganate-reducing substances  
Measure 100 mL of the test solution in a glass-stoppered, Erlenmeyer flask, add 10.0 mL of 0.002 mol/L potassium permanganate VS and 5 mL of dilute sulfuric acid, and boil for 3 minutes. After cooling, add 0.10 g of potassium iodide, stopper, mix by shaking, then allow to stand for 10 minutes, and titrate <2.50> with 0.01 mol/L sodium thiosulfate VS (indicator: 5 drops of starch TS). Perform the blank test in the same manner, using 100 mL of the blank solution. The difference in mL of 0.002 mol/L potassium permanganate VS required between the tests is not more than 2.0 mL.

3.6. Residue on evaporation  
Measure 100 mL of the test solution, evaporate on a water bath to dryness, and dry the residue at 105°C for 1 hour. The mass of the residue is not more than 2.0 mg.

3.7. UV spectrum  
Read the absorbance of the test solution between 220 nm and 350 nm against the blank solution as directed under Ultraviolet-visible Spectrophotometry <2.5>: it is not more than 0.20.

4. Acute systemic toxicity  
The test solution meets the requirements, when examined under the following conditions against the blank solution.

4.1. Preparation of the test solution and the blank solution  
Wash the rubber closures with water and Water for Injection successively, and dry under clean conditions at room temperature. Transfer the rubber closures to a glass container. Add isotonic sodium chloride solution 10 times the mass of the test material, stopper adequately, heat in an autoclave at 121°C for 1 hour, take out the glass container, and allow to cool to room temperature. The solution thus obtained is used as the test solution. The blank solution is prepared in the same manner.

4.2. Test procedures  

(i) Test animals: Use healthy male mice of inbred strain or from a closed colony, weighing 17 to 23 g.

(ii) Procedure: Separate the animals into two groups of 10 mice, and inject intravenously 50 mL each of the solutions per kg body mass.

4.3. Interpretation  
Observe the animals for 5 days after injection: During the observation period, none of the animals treated with the test solution show any abnormality or death.

5. Pyrogen test  
The test solution specified in 4.1. meets the requirements of the Pyrogen Test <4.04> as does the blank solution.

6. Hemolysis test  
When 0.1 mL of defibrinated blood of rabbit is added to 10 mL of the test solution specified in 4.1. and the mixture is allowed to stand at 37°C for 24 hours, hemolysis is not observed. Perform the blank test in the same manner, using 10 mL of the blank solution.

8. Other Methods

8.01 Sterilization and Aseptic Manipulation

1. Sterilization  
Sterilization means a process whereby the killing or removal of all living microorganisms is accomplished. Generally, the sterilization process requires the choice of appropriate procedure and accurately controlled operation and conditions depending on the kind of microorganism, the conditions of contamination and the quality and nature of the substance to be sterilized.

The adequacy of sterilization is decided by means of the Sterility Test <4.06>.

The procedure for sterilization should be carried out after confirming that the temperature, pressure, etc. are adequate for the desired sterilization.

For the choice of the conditions for sterilization or verification of the integrity of sterilization, biological indicators suitable for individual conditions of sterilization may be used.

2. Aseptic manipulation  
Aseptic manipulation is a technique used for processing the sterile drug products which are not terminally sterilized in their final containers, and applied to a series of aseptic processing of the sterile products which are prepared by filtration sterilization and/or with sterile raw materials.

Generally, aseptic manipulation requires the presterilization of all equipments and materials used for processing the sterile products, and then the products are processed in a way to give a defined sterility assurance level in the aseptic processing facilities where microbial and particulate levels are adequately maintained.
9. Reference Standards; Standard Solutions; Reagents, Test Solutions; Measuring Instruments, Appliances, etc.

Reference Standards

9.01 Reference Standards

Reference Standards are the reference substances prepared to a specified quality necessary with regard to their intended use as prescribed in monographs of the Pharmacopoeia. The Japanese Pharmacopoeia Reference Standards are as follows:

1) The reference standards which are prepared by those who have been registered to prepare them by the Minister of Health, Labour and Welfare, according to the Ministerial ordinance established by the Minister separately.

- Aceglutamide RS
- Acetaminophen RS
- Aciclovir RS
- Adrenaline Bitartrate RS
- Alendronate Sodium RS
- Alprostadil RS
- p-Aminobenzoyl Glutamic Acid RS
- Amitriptyline Hydrochloride RS
- Amlexanox RS
- Amlodipine Besilate RS
- Anhydrous Lactose RS
- Ascorbic Acid RS
- Aspirin RS
- Atorvastatin Calcium RS
- Atropine Sulfate RS
- Azathioprine RS
- Baclofen RS
- Baicalin RS
- Beclometasone Dipropionate RS
- Berberine Chloride RS
- Betamethasone RS
- Betamethasone Sodium Phosphate RS
- Betamethasone Valerate RS
- Bisacodyl RS
- Caffeine RS
- Calcitonin (Salmon) RS
- Calcium Folinate RS
- Calcium Oxalate Monohydrate RS
- Camostat Mesilate RS
- d-Camphor RS
- dl-Camphor RS
- Carbide RS
- Cellacefate RS
- Chlordiazepoxide RS
- Chlormadinone Acetate RS
- Chlormpheniramime Maleate RS
- Cholecalciferol RS
- Ciclosporin RS
- Cilostazol RS
- Cisplatin RS
- Clopenterol Propionate RS
- Clofibrate RS
- Clomifene Citrate RS
- Cortisone Acetate RS
- Cyanocobalamin RS
- Danazol RS
- Deferoxamine Mesilate RS
- Desflanoside RS

Standard Solutions

9.21 Standard Solutions for Volumetric Analysis

Standard Solutions for Volumetric Analysis are the solutions of reagent with an accurately known concentration, mainly used for the volumetric analysis. They are prepared to a specified molar concentration. A 1 molar solution is a solution which contains exactly 1 mole of a specified substance in each 1000 mL of the solution and is designated as 1 mol/L. If necessary, these solutions are diluted to other specified molar concentrations and the diluted solutions are also used as standard solutions. For example, 0.1 mol/L solution is obtained by diluting 1 mol/L solution 10 times by volume.

Unless otherwise directed, standard solutions for volumetric analysis should be stored in colorless or light-resistant, glass-stoppered bottles.

Preparation and Standardization

A volumetric standard solution is prepared according to one of the following methods. The degree of difference from a specified concentration \( n \) (mol/L) is expressed as a factor (molar concentration coefficient) \( f \). Usually, standard solutions are prepared so that the factor is in the range of 0.970 – 1.030. The determination procedure of the factor is called standardization of the standard solution.

1. Weigh accurately a quantity equivalent to about 1 mole or its multiple or a fractional mole number of the pure substance, and dissolve it in the specified solvent to make exactly 1000 mL to prepare a standard solution having a concentration close to exactly 1 mole or its multiple or a fractional mole number of the specified molar concentration and the diluted solutions are also used as standard solutions. For example, 0.1 mol/L solution is obtained by diluting 1 mol/L solution 10 times by volume.

When a pure substance is not obtainable, it is permissible to use a highly purified substance whose purity has been exactly determined and certified.

2. In the case where a pure substance or a highly purified substance is not obtainable, weigh a quantity equivalent to about 1 mole or its multiple or a fractional mole number of the substance specified for each standard solution and dissolve it in the specified solvent to make about 1000 mL to prepare a standard solution having a concentration close to the specified molar concentration of the substance (g) and the specified molar concentration number \( n \).

When a pure substance is not obtainable, it is permissible to use a highly purified substance whose purity has been exactly determined and certified.

Standardization

The degree of difference from a specified molar concentration \( n \) (mol/L) is obtained by applying the following equation.

\[
f = \frac{1000m}{VMn}
\]

Where:

- \( m \): Mass of the standard reagent or the specified substance (g)
- \( V \): Volume of the prepared standard solution consumed for the titration (mL)
- \( n \): Arithmetical mole number of the specified molar concentration of the solution to be standardized (e.g. \( n = 0.02 \) for 0.02 mol/L standard solution)
- \( f \): Factor of the titrating standard solution having a known factor
- \( f_1 \): Factor of the titrating standard solution having a known factor
- \( V_1 \): Volume of the titrating standard solution consumed (mL)
- \( V_2 \): Volume of the prepared standard solution taken (mL)

(3) Standard solutions may be prepared by diluting exactly an accurately measured volume of a standard solution having a known factor, according to the specified dilution procedure. During this dilution procedure, the original factor of the standard solution is assumed to remain constant.

Ammonium Iron (II) Sulfate, 0.1 mol/L

1000 mL of this solution contains 39.214 g of ammonium iron (II) sulfate hexahydrate \([\text{Fe}(\text{NH}_4)\text{SO}_4\cdot6\text{H}_2\text{O}: 392.14]\).

Preparation—Dissolve 49 g of ammonium iron (II) sulfate hexahydrate in a cooled mixture of 30 mL of sulfuric acid and 300 mL of water, dilute with water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 25 mL of the prepared ammonium iron (II) sulfate solution, and add 25 mL of water and 5 mL of phosphoric acid. Titrate \( <2.50 \) the solution with 0.02 mol/L potassium permanganate VS. Calculate the molarity factor.

Note: Prepare before use.

Ammonium Iron (II) Sulfate, 0.02 mol/L

1000 mL of this solution contains 7.843 g of ammonium iron (II) sulfate hexahydrate \([\text{Fe}(\text{NH}_4)\text{SO}_4\cdot6\text{H}_2\text{O}: 392.14]\).

Preparation—Before use, dilute 0.1 mol/L ammonium iron (II) sulfate VS with diluted sulfuric acid (3 in 100) to make exactly 5 times the initial volume.

Ammonium Iron (III) Sulfate, 0.1 mol/L

1000 mL of this solution contains 48.22 g of ammonium iron (III) sulfate dodecahydrate \([\text{FeNH}_4\text{SO}_4\cdot12\text{H}_2\text{O}: 482.19]\).

Preparation—Dissolve 49 g of ammonium iron (III) sulfate dodecahydrate in a cooled mixture of 6 mL of sulfuric acid and 300 mL of water, add water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 25 mL of the prepared ammonium iron (III) sulfate solution into an iodine flask, add 5 mL of hydrochloric acid, and shake the mixture. Dis-
solve 2 g of potassium iodide, and stopper the flask. After allowing the mixture to stand for 10 minutes, add 50 mL of water, and titrate 2.50 g of the liberated iodine with 0.1 mol/L sodium thiosulfate VS. When the solution assumes a pale yellow color as the end point is approached, add 3 mL of starch TS. Continue the titration, until the blue color disappears. Perform a blank determination. Calculate the molarity factor.

Note: Store protected from light. This solution, if stored for a long period of time, should be restandardized.

Ammonium Thiocyanate, 0.1 mol/L
1000 mL of this solution contains 7.612 g of ammonium thiocyanate (NH$_4$SCN; 76.12).

Preparation—Dissolve 8 g of ammonium thiocyanate in water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 25 mL of the 0.1 mol/L silver nitrate VS, and add 50 mL of water, 2 mL of nitric acid and 2 mL of ammonium iron (III) sulfate TS. Titrate 2.50 g of the solution with the prepared ammonium thiocyanate solution to the first appearance of a persistent red-brown color with shaking. Calculate the molarity factor.

Note: Store protected from light.

Ammonium Thiocyanate, 0.02 mol/L
1000 mL of this solution contains 1.5224 g of ammonium thiocyanate (NH$_4$SCN; 76.12).

Preparation—Before use, dilute 0.1 mol/L ammonium thiocyanate VS with water to make exactly 5 times the initial volume.

Barium chloride, 0.1 mol/L
1000 mL of this solution contains 24.426 g of barium chloride dihydrate (BaCl$_2$.2H$_2$O; 244.26).

Preparation—Dissolve 24.5 g of barium chloride dihydrate in water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 20 mL of the prepared solution, add 3 mL of hydrochloric acid, and warm the mixture. Add 40 mL of diluted sulfuric acid (1 in 130), previously warmed, heat the mixture on a water bath for 30 minutes, and allow it to stand overnight. Filter the mixture, wash the precipitate on the filter paper with water until the last washing shows no turbidity with silver nitrate TS, transfer the precipitate together with the filter paper to a tared crucible, and then heat strongly to ashes. After cooling, add 2 drops of sulfuric acid, and heat strongly again at about 700°C for 2 hours. After cooling, weigh accurately the residue as barium sulfate (BaSO$_4$), and calculate the molarity factor.

Each mL of 0.02 mol/L barium chloride VS
= 4.668 mg of BaSO$_4$

Barium Chloride, 0.01 mol/L
1000 mL of this solution contains 2.4426 g of barium chloride dihydrate (BaCl$_2$.2H$_2$O; 244.26).

Preparation—Before use, dilute 0.02 mol/L barium chloride VS with water to make exactly twice the initial volume.

Barium Perchlorate, 0.005 mol/L
1000 mL of this solution contains 1.6812 g of barium perchlorate [Ba(ClO$_4$)$_2$; 336.23].

Preparation—Dissolve 1.7 g of barium perchlorate in 200 mL of water, dilute with 2-propanol to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 20 mL of the prepared barium perchlorate solution, add 55 mL of methanol and 0.15 mL of arsenazo III TS. Titrate 2.50 g of the solution with 0.005 mol/L sulfuric acid VS until its purple color changes through red-purple to red. Calculate the molarity factor.

Bismuth Nitrate, 0.01 mol/L
1000 mL of this solution contains 4.851 g of bismuth nitrate pentahydrate [Bi(NO$_3$)$_3$.5H$_2$O; 485.07].

Preparation—Dissolve 4.86 g of bismuth nitrate pentahydrate in 60 mL of dilute nitric acid, add water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 25 mL of the prepared bismuth nitrate solution, add 50 mL of water and 1 drop of xyleneorange TS, and titrate 2.50 g of the solution with 0.01 mol/L disodium dihydrogen ethylenediamine tetracetate VS until the red color changes to yellow. Calculate the molarity factor.

Bromine, 0.05 mol/L
1000 mL of this solution contains 7.990 g of bromine (Br; 79.90).

Preparation—Dissolve 2.8 g of potassium bromate and 15 g of potassium bromide in water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 25 mL of the prepared solution into an iodine flask. Add 120 mL of water, quickly add 5 mL of hydrochloric acid, stopper the flask immediately, and shake it gently. Then add 5 mL of potassium iodide TS, re-stopper immediately, shake the mixture gently, and allow to stand for 5 minutes. Titrate 2.50 g of the liberated iodine with 0.1 mol/L sodium thiosulfate VS. When the solution assumes a pale yellow color as the end point is approached, add 3 mL of starch TS. Continue the titration, until the blue color disappears. Perform a blank determination. Calculate the molarity factor.
Ceric Ammonium Sulfate, 0.1 mol/L
See cerium (IV) tetraammonium sulfate, 0.1 mol/L.

Ceric Ammonium Sulfate, 0.01 mol/L
See cerium (IV) tetraammonium sulfate, 0.01 mol/L.

Cerium (IV) Tetraammonium Sulfate, 0.1 mol/L
1000 mL of this solution contains 63.26 g of cerium (IV) tetraammonium sulfate dihydrate \([\text{Ce}(\text{NH}_3)_4(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}: 632.55]\).

**Preparation**—Dissolve 64 g of cerium (VI) tetraammonium sulfate dihydrate in 0.5 mol/L sulfuric acid VS to make 1000 mL, allow to stand for 24 hours, filter the solution through a glass filter (G3 or G4), if necessary, and standardize the solution as follows:

**Standardization**—Measure exactly 25 mL of the prepared cerium (IV) tetraammonium sulfate solution into an iodine flask. Add 20 mL of water and 20 mL of dilute sulfuric acid, then dissolve 1 g of potassium iodide in the mixture. Immediately titrate with 0.1 mol/L sodium thiosulfate VS. When the solution assumes a pale yellow color as the end point is approached, add 3 mL of starch TS. Continue the titration until the blue color disappears. Perform a blank determination. Calculate the molarity factor.

Note: Store protected from light. This solution, if stored for a long period of time, should be restandardized.

Cerium (IV) Tetraammonium Sulfate, 0.01 mol/L
1000 mL of this solution contains 6.326 g of cerium (IV) tetraammonium sulfate dihydrate \([\text{Ce}(\text{NH}_3)_4(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}: 632.55]\).

**Preparation**—Before use, dilute 0.1 mol/L cerium (IV) tetraammonium sulfate VS with 0.5 mol/L sulfuric acid VS to make exactly 10 times the initial volume.

Disodium Dihydrogen Ethylenediamine Tetraacetate, 0.1 mol/L
1000 mL of this solution contains 37.224 g of disodium dihydrogen ethylenediamine tetraacetate dihydrate \((\text{C}_{10}\text{H}_{14}\text{N}_2\text{Na}_2\text{O}_8 \cdot 2\text{H}_2\text{O}: 372.24)\).

**Preparation**—Dissolve 38 g of disodium dihydrogen ethylenediamine tetraacetate dihydrate in water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Wash zinc (standard reagent) with dilute hydrochloric acid, water and then acetone, dry at 110°C for 5 minutes, and allow to cool in a desiccator (silica gel). Weigh accurately about 0.8 g of this zinc, add 12 mL of dilute hydrochloric acid and 5 drops of bromine TS, and dissolve it by gentle warming. Expel any excess of bromine by boiling, and add water to make exactly 200 mL. Pipet 25 mL of this solution, and neutralize with sodium hydroxide solution (1 in 50). Add 5 mL of ammonia-ammonium chloride buffer solution, pH 10.7, and 0.04 g of eriochrome black T-sodium chloride indicator. Titrate with 0.1 mol/L sodium hydroxide solution (1 in 50) to form a blank determination. Calculate the molarity factor.

Each mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS

\[
= 3.269 \text{ mg of Zn}
\]

Note: Store in polyethylene bottles.
**Preparation**—Before use, dilute 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate VS with water to make exactly 10 times the initial volume.

**Ferric Ammonium Sulfate, 0.1 mol/L**
See Ammonium Iron (III) Sulfate, 0.1 mol/L.

**Ferrous Ammonium Sulfate, 0.1 mol/L**
See Ammonium Iron (II) Sulfate, 0.1 mol/L.

**Ferrous Ammonium Sulfate, 0.02 mol/L**
See Ammonium Iron (II) Sulfate, 0.02 mol/L.

**Hydrochloric Acid, 2 mol/L**
1000 mL of this solution contains 72.92 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Dilute 180 mL of hydrochloric acid with water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Proceed as directed for standardization under 1 mol/L hydrochloric acid VS, but weigh about 1.5 g of sodium carbonate (standard reagent) accurately, and dissolve in 100 mL of water.

Each mL of 2 mol/L hydrochloric acid VS
\[= 106.0 \text{ mg of Na}_2\text{CO}_3\]

**Hydrochloric Acid, 1 mol/L**
1000 mL of this solution contains 36.461 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Dilute 90 mL of hydrochloric acid with water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Weigh accurately about 0.8 g of sodium carbonate (standard reagent), previously heated between 500°C and 650°C for 40 to 50 minutes and allowed to cool in a desiccator (silica gel). Dissolve it in 50 mL of water, and titrate \(0.2500\) with the prepared hydrochloric acid to calculate the molarity factor (Indicator method: 3 drops of methyl red TS; or potentiometric titration). In the indicator method, when the end-point is approached, boil the content carefully, stopper the flask loosely, allow to cool, and continue the titration until the color of the solution changes to persistent orange to orange-red. In the potentiometric titration, titrate with vigorous stirring, without boiling.

Each mL of 1 mol/L hydrochloric acid VS
\[= 53.00 \text{ mg of Na}_2\text{CO}_3\]

**Hydrochloric Acid, 0.5 mol/L**
1000 mL of this solution contains 18.230 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Dilute 45 mL of hydrochloric acid with water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Proceed as directed for standardization under 1 mol/L hydrochloric acid VS, but weigh accurately about 0.4 g of sodium carbonate (standard reagent), and dissolve in 50 mL of water.

Each mL of 0.5 mol/L hydrochloric acid VS
\[= 26.50 \text{ mg of Na}_2\text{CO}_3\]

**Hydrochloric Acid, 0.2 mol/L**
1000 mL of this solution contains 7.292 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Dilute 18 mL of hydrochloric acid with water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Proceed as directed for standardization under 1 mol/L hydrochloric acid VS, but weigh accurately about 0.15 g of sodium carbonate (standard reagent), and dissolve in 30 mL of water.

Each mL of 0.2 mol/L hydrochloric acid VS
\[= 10.60 \text{ mg of Na}_2\text{CO}_3\]

**Hydrochloric Acid, 0.1 mol/L**
1000 mL of this solution contains 3.6461 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Before use, dilute 0.2 mol/L hydrochloric acid VS with water to make exactly twice the initial volume.

Each mL of 0.1 mol/L hydrochloric acid VS
\[= 5.300 \text{ mg of Na}_2\text{CO}_3\]

**Hydrochloric Acid, 0.05 mol/L**
1000 mL of this solution contains 1.8230 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Before use, dilute 0.2 mol/L hydrochloric acid VS with water to make exactly 4 times the initial volume.

**Hydrochloric Acid, 0.02 mol/L**
1000 mL of this solution contains 0.7292 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Before use, dilute 0.2 mol/L hydrochloric acid VS with water to make exactly 10 times the initial volume.

**Hydrochloric Acid, 0.01 mol/L**
1000 mL of this solution contains 0.36461 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Before use, dilute 0.2 mol/L hydrochloric acid VS with water to make exactly 20 times the initial volume.

**Hydrochloric Acid, 0.001 mol/L**
1000 mL of this solution contains 0.036461 g of hydrochloric acid (HCl: 36.46).

**Preparation**—Before use, dilute 0.2 mol/L hydrochloric acid VS with water to make exactly 200 times the initial volume.

**Iodine, 0.05 mol/L**
1000 mL of this solution contains 12.690 g of iodine (I: 126.90).

**Preparation**—Dissolve 13 g of iodine in 100 mL of a solution of potassium iodide (2 in 5), add 1 mL of dilute hydrochloric acid and water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Measure exactly 15 mL of the iodine solution, and titrate \(0.2500\) with 0.1 mol/L sodium thiosulfate VS (Indicator method: starch TS; or potentiometric titration: platinum electrode). In the indicator method, when the solution assumes a pale yellow color as the end point is approached, add 3 mL of starch TS, and continue the titration...
until the blue color disappears. Calculate the molarity factor.

Note: Store protected from light. This solution, if stored for a long period, should be restandardized before use.

**Iodine, 0.01 mol/L**

1000 mL of this solution contains 2.5381 g of iodine (I: 126.90).

**Preparation**—Before use, dilute 0.05 mol/L iodine VS with water to make exactly 5 times the initial volume.

**Iodine, 0.005 mol/L**

1000 mL of this solution contains 1.2690 g of iodine (I: 126.90).

**Preparation**—Before use, dilute 0.05 mol/L iodine VS with water to make exactly 10 times the initial volume.

**Iodine, 0.002 mol/L**

1000 mL of this solution contains 0.5076 g of iodine (I: 126.90).

**Preparation**—Before use, dilute 0.05 mol/L iodine VS with water to make exactly 25 times the initial volume.

**Magnesium Chloride, 0.05 mol/L**

1000 mL of this solution contains 10.165 g of magnesium chloride hexahydrate (MgCl₂·6H₂O: 203.30).

**Preparation**—Dissolve 10.2 g of magnesium chloride hexahydrate in freshly boiled and cooled water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Measure exactly 25 mL of the prepared magnesium chloride solution. Add 50 mL of water, 3 mL of pH 10.7 ammonia-ammonium chloride buffer solution and 0.04 g of eriochrome black T-sodium chloride indicator, and titrate with 0.05 mol/L disodium dihydrogen ethylenediamine tetracetate VS until the red-purple color of the solution changes to blue-purple. Calculate the molarity factor.

**Magnesium Chloride, 0.01 mol/L**

1000 mL of this solution contains 2.0330 g of magnesium chloride hexahydrate (MgCl₂·6H₂O: 203.30).

**Preparation**—Before use, dilute 0.05 mol/L magnesium chloride VS with water to make exactly 5 times the initial volume.

**Oxalic Acid, 0.05 mol/L**

1000 mL of this solution contains 6.303 g of oxalic acid (C₃H₂O₄·2H₂O: 126.07).

**Preparation**—Dissolve 6.3 g of oxalic acid dihydrate in water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Measure exactly 25 mL of the prepared oxalic acid solution in a 500-mL conical flask, and add 200 mL of diluted sulfuric acid (1 in 20), previously boiled for 10 to 15 minutes and then cooled to 27 ± 3°C. Transfer freshly standardized 0.02 mol/L potassium permanganate VS to a burette. Add quickly 22 mL of the 0.02 mol/L potassium permanganate VS to the oxalic acid solution from the burette under gentle stirring, and allow to stand until the red color of the mixture disappears. Heat the solution up to between 55°C and 60°C, and complete the titration with 0.03 mL of acetic anhydride with shaking at about 20°C. Calculate the molarity factor.

**Oxalic Acid, 0.005 mol/L**

1000 mL of this solution contains 0.6303 g of oxalic acid dihydrate (C₃H₂O₄·2H₂O: 126.07).

**Preparation**—Before use, dilute 0.05 mol/L oxalic acid VS with water to make exactly 10 times the initial volume.

**Perchloric Acid, 0.1 mol/L**

1000 mL of this solution contains 10.046 g of perchloric acid (HClO₄: 100.46).

**Preparation**—Add slowly 8.7 mL of perchloric acid to 1000 mL of acetic acid (100) while keeping the temperature at about 20°C. Allow the mixture to stand for about 1 hour. Perform quickly the test as directed under Water Determination with 3.0 mL of the mixture, and designate the water content as A (g/dL). To the rest mixture add slowly [(A – 0.03) × 52.2] mL of acetic anhydride with shaking at about 20°C. Allow the solution to stand for 24 hours, and standardize it as follows:

**Standardization**—Weigh accurately about 0.3 g of potassium hydrogen phthalate (standard reagent), previously dried at 105°C for 4 hours and allowed to cool in a desiccator (silica gel). Dissolve it in 50 mL of acetic acid (100), and titrate with 0.05 mol/L disodium dihydrogen ethylenediamine tetracetate VS until the red-purple color of the solution changes to blue-purple. Calculate the molarity factor.

**Perchloric Acid, 0.05 mol/L**

1000 mL of this solution contains 5.023 g of perchloric acid (HClO₄: 100.46).

**Preparation**—Before use, dilute 0.1 mol/L perchloric acid VS with acetic acid for nonaqueous titration to make exactly twice the initial volume. Perform quickly the test as directed under Water Determination with 8.0 mL of acetic acid for nonaqueous titration, and designate the water content as A (g/dL). If A is not less than 0.03, add [(A – 0.03) × 52.2] mL of acetic anhydride to 1000 mL of acetic acid for nonaqueous titration, and use it for the preparation.

**Perchloric Acid, 0.02 mol/L**

1000 mL of this solution contains 2.0092 g of perchloric acid (HClO₄: 100.46).

**Preparation**—Before use, dilute 0.1 mol/L perchloric acid VS with acetic acid for nonaqueous titration to make exactly 5 times the initial volume. Perform quickly the test as directed under Water Determination with 8.0 mL of acetic acid for nonaqueous titration, and designate the water content as A (g/dL). If A is not less than 0.03, add [(A – 0.03) × 52.2] mL of acetic anhydride to 1000 mL of acetic acid for nonaqueous titration, and use it for the preparation.

**Perchloric Acid-1,4-Dioxane, 0.1 mol/L**

1000 mL of this solution contains 10.046 g of perchloric acid (HClO₄: 100.46).
acids (HClO₄: 100.46).

**Preparation**—Dilute 8.5 mL of perchloric acid with 1,4-dioxane to make 1000 mL, and standardize the solution as follows:

**Standardization**—Weigh accurately about 0.5 g of potassium dichromate (standard reagent), previously dried at 105°C for 4 hours and allowed to cool in a desiccator (silica gel). Dissolve it in 80 mL of acetic acid for nonaqueous titration, and add 3 drops of crystal violet TS. Titrate ≤0.50 mL of the solution with the prepared perchloric acid-1,4-dioxane VS with 1,4-dioxane to make exactly twice the initial volume.

Each mL of 0.1 mol/L perchloric acid-1,4-dioxane VS with 1,4-dioxane to make exactly twice the initial volume.

**Perchloric Acid-1,4-Dioxane, 0.05 mol/L**
1000 mL of this solution contains 5.023 g of perchloric acid (HClO₄: 100.46).

**Preparation**—Before use, dilute 0.1 mol/L perchloric acid-1,4-dioxane VS with 1,4-dioxane to make exactly twice the initial volume.

**Perchloric Acid-1,4-Dioxane, 0.004 mol/L**
1000 mL of this solution contains 0.4018 g of perchloric acid (HClO₄: 100.46).

**Preparation**—Before use, dilute 0.1 mol/L perchloric acid-1,4-dioxane VS with 1,4-dioxane to make exactly 25 times the initial volume.

**Potassium Dichromate, 1/60 mol/L**
See Potassium Dichromate, 1/60 mol/L.

**Potassium Bromate, 1/60 mol/L**
1000 mL of this solution contains 2.7833 g of potassium bromate (KBrO₃: 187.00).

**Preparation**—Dissolve 2.8 g of potassium bromate in water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Measure exactly 25 mL of the prepared potassium bromate solution into an iodine flask. Add 2 g of potassium iodide and 5 mL of dilute sulfuric acid, stopper the flask, and allow the solution to stand for 5 minutes. Add 100 mL of water, and titrate ≤0.50 mL of the liberated iodine with 0.1 mol/L sodium thiosulfate VS. When the solution assumes a pale yellow color as the end point is approached, add 3 mL of starch TS. Continue the titration, until the blue color disappears. Perform a blank determination. Calculate the molarity factor.

Note: Store protected from light. This solution, if stored for a long period, should be restandardized.

**Potassium Hexacyanoferrate (III), 0.05 mol/L**
1000 mL of this solution contains 16.462 g of potassium hexacyanoferrate (III) [K₃Fe(CN)₆: 329.24].

**Preparation**—Before use, dilute 0.1 mol/L potassium hexacyanoferrate (III) VS with water to make exactly twice the initial volume.

**Potassium Hydroxide, 1 mol/L**
1000 mL of this solution contains 56.11 g of potassium hydroxide (KOH: 56.11).

**Preparation**—Dissolve 65 g of potassium hydroxide in 950 mL of water. Add a freshly prepared, saturated solution of barium hydroxide octahydrate until no more precipitate is produced. Shake the mixture thoroughly, and allow it to stand for 24 hours in a tightly stoppered bottle. Decant the supernatant liquid or filter the solution through a glass filter (G3 or G4), and standardize the solution as follows:

**Standardization**—Weigh accurately about 2.5 g of amidosulfuric acid (standard reagent), previously dried in a desiccator (in vacuum, silica gel) for about 48 hours. Dissolve it in 25 mL of freshly boiled and cooled water, and add 2 drops of bromothymol blue TS. Titrate ≤0.50 mL of the solution with the prepared potassium hydroxide solution until it acquires a green color. Calculate the molarity factor.

Note: Store in tightly stoppered bottles or in containers provided with a carbon dioxide-absorbing tube (soda-lime). This solution, if stored for a long period, should be restandardized.

**Potassium Hydroxide, 0.5 mol/L**
1000 mL of this solution contains 28.053 g of potassium hydroxide (KOH: 56.11).

**Preparation**—Weigh 32 g of potassium hydroxide, proceed as directed for preparation under 1 mol/L potassium hydroxide VS, and standardize the solution as follows:

**Standardization**—Proceed as directed for standardization under 1 mol/L potassium hydroxide VS, but weigh accurately about 1.3 g of amidosulfuric acid (standard reagent).
Each mL of 0.5 mol/L potassium hydroxide VS = 48.55 mg of HOSO₂NH₂

Note: Store as directed under 1 mol/L potassium hydroxide VS. This solution, if stored for a long period, should be restandardized.

Potassium Hydroxide-ethanol, 0.5 mol/L
1000 mL of this solution contains 28.053 g of potassium hydroxide (KOH: 56.11).

Preparation—Dissolve 35 g of potassium hydroxide in 20 mL of water, and add aldehyde-free ethanol to make 1000 mL. Allow the solution to stand for 24 hours in a tightly stoppered bottle. Then quickly decant the supernatant liquid, and standardize the solution as follows:

Standardization—Measure exactly 15 mL of 0.25 mol/L sulfuric acid VS, add 50 mL of water, and titrate with the prepared potassium-hydroxide-ethanol solution to calculate the molarity factor (indicator method: 2 drops of phenolphthalein TS or potentiometric titration). In the indicator method, titrate <2.50 mL until the solution acquires a pale red color.

Note: Store in tightly stoppered bottles, protected from light. Standardize before use.

Potassium Hydroxide-ethanol, 0.1 mol/L
1000 mL of this solution contains 5.611 g of potassium hydroxide (KOH: 56.11).

Preparation—Weigh 7 g of potassium hydroxide, proceed as directed for preparation under 0.5 mol/L potassium hydroxide-ethanol VS, and standardize the solution as follows:

Standardization—Proceed as directed for standardization under 0.5 mol/L potassium hydroxide-ethanol VS, but measure exactly 15 mL of 0.05 mol/L sulfuric acid VS.

Note: Store as directed under 0.5 mol/L potassium hydroxide-ethanol VS. Standardize before use.

Potassium Iodate, 0.05 mol/L
1000 mL of this solution contains 10.700 g of potassium iodate (KIO₃: 214.00).

Preparation—Weigh accurately about 10.700 g of potassium iodate (standard reagent), previously dried between 120°C and 140°C for 2 hours and allowed to cool in a desiccator (silica gel), and dissolve it in water to make exactly 1000 mL. Calculate the molarity factor.

Each mL of 0.02 mol/L potassium permanganate VS = 6.700 mg of Na₂C₂O₄

Note: Store protected from light. This solution, if stored for a long period, should be restandardized.

Potassium Permanganate, 0.002 mol/L
1000 mL of this solution contains 0.31607 g of potassium permanganate (KMnO₄: 158.03).

Preparation—Dissolve 3.2 g of potassium permanganate in water to make 1000 mL, and boil the solution for 15 minutes. Allow the solution to stand for at least 48 hours in a tightly stoppered flask, and filter it through a glass filter (G3 or G4). Standardize the solution as follows:

Standardization—Weigh accurately about 0.3 g of sodium oxalate (standard reagent), previously dried between 150°C and 200°C for 1 to 1.5 hours and allowed to cool in a desiccator (silica gel), transfer it to a 500 mL conical flask, dissolve in 30 mL of water, add 250 mL of diluted sulfuric acid (1 in 20), and warm the mixture between 30°C and 35°C. Transfer the prepared potassium permanganate solution to a buret, add quickly 40 mL of the solution under gentle stirring from the buret, and allow to stand until the red color of the mixture disappears. Warm the solution between 55°C and 60°C, and complete the titration <2.50 mL> with the potassium permanganate solution until a faint red color persists for 30 seconds. Add the last 0.5 to 1 mL dropwise before the end point, being particularly careful to allow the solution to be decolorized before the next drop is added. Calculate the molarity factor.

Each mL of 0.02 mol/L potassium permanganate VS = 6.700 mg of Na₂C₂O₄

Note: Store protected from light. This solution, if stored for a long period, should be restandardized.

Silver Nitrate, 0.1 mol/L
1000 mL of this solution contains 16.987 g of silver nitrate (AgNO₃: 169.87).

Preparation—Dissolve 17.0 g of silver nitrate in water to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh accurately about 80 mg of sodium chloride (standard reagent), previously dried between 500°C and 650°C for 40 to 50 minutes and allowed to cool in
a desiccator (silica gel), dissolve it in 50 mL of water, and titrate \( \leq 2.50 \) under vigorous stirring with the prepared silver nitrate solution to calculate the molarity factor (Indicator method: 3 drops of fluorescein sodium TS; or potentiometric titration: silver electrode). In the indicator method, titrate until the color of the solution changes from yellow-green to orange through yellow.

Each mL of 0.1 mol/L silver nitrate VS = 5.844 mg of NaCl

Note: Store protected from light.

### Silver Nitrate, 0.02 mol/L

1000 mL of this solution contains 3.3974 g of silver nitrate (AgNO₃: 169.87).

**Preparation**—Before use, dilute 0.1 mol/L silver nitrate VS with water to make exactly 5 times the initial volume.

### Silver Nitrate, 0.01 mol/L

1000 mL of this solution contains 1.6987 g of silver nitrate (AgNO₃: 169.87).

**Preparation**—Before use, dilute 0.1 mol/L silver nitrate VS with water to make exactly 10 times the initial volume.

### Silver Nitrate, 0.005 mol/L

1000 mL of this solution contains 0.8494 g of silver nitrate (AgNO₃: 169.87).

**Preparation**—Before use, dilute 0.1 mol/L silver nitrate VS with water to make exactly 20 times the initial volume.

### Silver Nitrate, 0.001 mol/L

1000 mL of this solution contains 0.16987 g of silver nitrate (AgNO₃: 169.87).

**Preparation**—Dilute 0.1 mol/L silver nitrate VS with water to make exactly 100 times of the initial volume before use.

### Sodium Acetate, 0.1 mol/L

1000 mL of this solution contains 8.203 g of sodium acetate (CH₃COONa: 82.03).

**Preparation**—Dissolve 8.20 g of anhydrous sodium acetate in acetic acid (100) to make 1000 mL, and standardize the solution as follows:

**Standardization**—Pipet 25 mL of the prepared sodium acetate solution, add 50 mL of acetic acid (100) and 1 mL of p-naphtholbenzene TS, and titrate \( < 2.50 \) with 0.1 mol/L perchloric acid VS until a yellow-brown color changes through yellow to green. Perform a blank determination. Calculate the molarity factor.

### Sodium Acetate, 0.2 mol/L

1000 mL of this solution contains 19.42 mg of HOSO₂NH₂

**Preparation**—Weigh 9 g of sodium hydroxide, proceed as directed for standardization under 1 mol/L sodium hydroxide VS, but weigh accurately about 0.3 g of amidosulfuric acid (standard reagent).

Each mL of 0.2 mol/L sodium hydroxide VS = 48.55 mg of HOSO₂NH₂

Note: Store as directed under 1 mol/L sodium hydroxide VS. This solution, if stored for a long period, should be restandardized.

### Sodium Acetate, 0.5 mol/L

1000 mL of this solution contains 48.55 mg of HOSO₂NH₂

**Preparation**—Weigh 4.5 g of sodium hydroxide, proceed as directed for standardization under 1 mol/L sodium hydroxide VS, but weigh accurately about 0.15 g of amidosulfuric acid (standard reagent).

Each mL of 0.5 mol/L sodium hydroxide VS = 97.09 mg of HOSO₂NH₂

Note: Store as directed under 1 mol/L sodium hydroxide VS. This solution, if stored for a long period, should be restandardized.

### Sodium Acetate, 1 mol/L

1000 mL of this solution contains 97.09 mg of HOSO₂NH₂

**Preparation**—Weigh 42 g of sodium hydroxide in 950 mL of water. Add a freshly prepared, saturated solution of barium hydroxide octahydrate until no more precipitate is produced. Mix well the mixture, and allow to stand for 24 hours in a tightly stoppered bottle. Decant the supernatant liquid or filter the solution through a glass filter (G3 or G4), and standardize the solution as follows:

**Standardization**—Weigh accurately about 1.5 g of amidosulfuric acid (standard reagent), previously dried in a desiccator (in vacuum, silica gel) for about 48 hours. Dissolve it in 25 mL of freshly boiled and cooled water, and titrate \( < 2.50 \) with the solution with the prepared sodium hydroxide solution to calculate the molarity factor (Indicator method: 2 drops of bromothymol blue TS; or potentiometric titration). In the indicator method, titrate until the solution acquires a green color.

Each mL of 1 mol/L sodium hydroxide VS = 9.709 mg of HOSO₂NH₂

Note: Store in tightly stoppered bottles or in containers provided with a carbon dioxide-absorbing tube (soda lime). This solution, if stored for a long period, should be restandardized.
Sodium Hydroxide, 0.05 mol/L
1000 mL of this solution contains 1.9999 g of sodium hydroxide (NaOH: 40.00).
Preparation—Before use, dilute 0.1 mol/L sodium hydroxide VS with freshly boiled and cooled water to make exactly twice the initial volume.

Sodium Hydroxide, 0.02 mol/L
1000 mL of this solution contains 0.7999 g of sodium hydroxide (NaOH: 40.00).
Preparation—Before use, dilute 0.1 mol/L sodium hydroxide VS with freshly boiled and cooled water to make exactly 5 times the initial volume.

Sodium Hydroxide, 0.01 mol/L
1000 mL of this solution contains 0.39997 g of sodium hydroxide (NaOH: 40.00).
Preparation—Before use, dilute 0.1 mol/L sodium hydroxide VS with freshly boiled and cooled water to make exactly 10 times the initial volume.

Sodium Hydroxide-Ethanol, 0.025 mol/L
1000 mL of this solution contains 1.000 g of sodium hydroxide (NaOH: 40.00).
Preparation—Dissolve 2.1 g of sodium hydroxide in 100 mL of ethanol (99.5), stopper tightly, and allow to stand for a night. To 50 mL of the supernatant liquid add 650 mL of ethanol (99.5) and freshly boiled and cooled water to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh accurately about 25 mg of amidosulfuric acid (standard reagent), previously dried in a desiccator (in vacuum, silica gel) for 48 hours. Dissolve in 30 mL of diluted ethanol (99.5) with fleshly boiled and cooled water (7 in 10), and titrate <2.50 with the prepared sodium hydroxide-ethanol to calculate the molarity factor (potentiometric titration).

Each mL of 0.025 mol/L sodium hydroxide-ethanol VS = 2.427 mg of HOSO₂NH₂
Note: Store in light-resistant, well-stoppered bottles. The standardization should be performed before using.

Sodium Lauryl Sulfate, 0.01 mol/L
1000 mL of this solution contains 2.8838 g of sodium lauryl sulfate (C₁₂H₂₅NaO₄S: 288.38).
Preparation—Dissolve 2.9 g of sodium lauryl sulfate in water to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh accurately about 0.3 g of papaerine hydrochloride for assay, previously dried, and dissolve in water to make exactly 100 mL. Pipet 10 mL of this solution into a glass-stoppered conical flask, add 5 mL each of water and dilute sulfuric acid and 60 mL of dichloromethane, then add 5 to 6 drops of a solution of methyl yellow in dichloromethane (1 in 500) as indicator, and titrate <2.50 with the vigorous shaking, with the sodium lauryl sulfate solution prepeared above, using a buret with a minimum graduation of 0.02 mL. End point is reached when the color of the dichloromethane layer changes from yellow to orange-red after dropwise addition of the sodium lauryl sulfate solution, vigorous shaking and standing for a while.

Each mL of 0.01 mol/L sodium lauryl sulfate VS = 3.759 mg of C₁₂H₂₅NaO₄S·HCl

Sodium Methoxide, 0.1 mol/L
1000 mL of this solution contains 5.402 g of sodium methoxide (CH₃ONa: 54.02).
Preparation—Add little by little 2.5 g of freshly cut sodium pieces to 150 mL of methanol cooled in ice-water. After the sodium has dissolved, add benzene to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh accurately about 3 g of benzoic acid, previously dried for 24 hours in a desiccator (silica gel), dissolve it in 80 mL of N,N-dimethylformamide, and add 3 drops of thymol blue-N,N-dimethylformamide TS. Titrate <2.50 the solution with the prepared sodium methoxide solution until a blue color appears. Perform a blank determination. Calculate the molarity factor.

Each mL of 0.1 mol/L sodium methoxide VS = 12.21 mg of CH₃COOH
Note: Store in a cold place, protected from moisture. Standardize before use.

Sodium Methoxide-Dioxane, 0.1 mol/L
See Sodium Methoxide-1,4-Dioxane, 0.1 mol/L.

Sodium Methoxide-1,4-Dioxane, 0.1 mol/L
1000 mL of this solution contains 5.402 g of sodium methoxide (CH₃ONa: 54.02).
Preparation—Add little by little 2.5 g of freshly cut sodium pieces to 150 mL of methanol cooled in ice-water. After the sodium has dissolved, add 1,4-dioxane to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh accurately about 0.3 g of benzoic acid, previously dried in a desiccator (silica gel) for 24 hours, dissolve it in 80 mL of N,N-dimethylformamide, and add 3 drops of thymol blue-N,N-dimethylformamide TS. Titrate <2.50 the solution with the prepared sodium methoxide-1,4-dioxane solution until a blue color appears. Perform a blank determination. Calculate the molarity factor.

Each mL of 0.1 mol/L sodium methoxide-1,4-dioxane VS = 12.21 mg of CH₃COOH
Note: Store in a cold place, protected from moisture. Standardize before use.

Sodium Nitrite, 0.1 mol/L
1000 mL of this solution contains 6.900 g of sodium nitrite (NaNO₂: 69.00).
Preparation—Dissolve 7.2 g of sodium nitrite in water to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh accurately about 0.44 g of sulfanilamide for titration of diazotization, previously dried at 105°C for 3 hours and allowed to cool in a desiccator (silica gel), dissolve in 10 mL of hydrochloric acid, 40 mL of water and 10 mL of a solution of potassium bromide (3 in 10), cool below 15°C, and titrate with the prepared sodium nitrite solution as directed in the potentiometric titration or amperometric titration under Endpoint Detection Methods in Titrimetry <2.50. Calculate the molarity factor.

Each mL of 0.1 mol/L sodium nitrite VS = 17.22 mg of H₂N₂C₆H₄SO₂NH₂
Note: Store protected from light. This solution, if stored for a long period, should be restandardized.

**Sodium Oxalate, 0.005 mol/L**

100 mL of this solution contains 0.6700 g of sodium oxalate (Na₂C₂O₄; 134.00).

Preparation—Weigh accurately about 0.6700 g of sodium oxalate (standard reagent), previously dried between 150°C and 200°C for 2 hours and allowed to cool in a desiccator (silica gel), dissolve it in water to make exactly 1000 mL, and calculate the molarity factor.

**Sodium Tetraphenylborate, 0.02 mol/L**

1000 mL of this solution contains 6.844 g of sodium tetraphenylborate [NaB(C₆H₅)₄; 342.22].

Preparation—Dissolve 7.0 g of sodium tetraphenylborate in water to make 1000 mL, and standardize the solution as follows:

Standardization—Weigh 0.5 g of potassium hydrogen phthalate (standard reagent), dissolve it in 100 mL of water, add 2 mL of acetic acid (31), and warm to 50°C in a water bath. Add slowly 50 mL of the prepared sodium tetraphenylborate solution under stirring from a buret, then cool the mixture quickly, and allow to stand for 1 hour at room temperature. Transfer the precipitate to a tared glass filter (G4), wash three 5 mL portions of potassium tetraphenylborate TS, dry at 105°C for 1 hour, and weigh accurately the glass filter. Calculate the molarity factor from the mass of potassium tetraphenylborate [KB(C₆H₅)₄; 358.32].

Each mL of 0.02 mol/L sodium tetraphenylborate VS = 7.166 mg of KB(C₆H₅)₄

Note: Prepare before use.

**Sodium Tetraphenylboron, 0.02 mol/L**

See Sodium Tetraphenylborate, 0.02 mol/L.

**Sodium Thiosulfate, 0.1 mol/L**

1000 mL of this solution contains 24.818 g of sodium thiosulfate pentahydrate (Na₂S₂O₃.5H₂O: 248.18).

Preparation—Dissolve 25 g of sodium thiosulfate and 0.2 g of anhydrous sodium carbonate in freshly boiled and cooled water to make 1000 mL, allow to stand for 24 hours, and standardize the solution as follows:

Standardization—Weigh accurately about 30 mg of potassium iodate (standard reagent), previously dried between 120°C and 140°C for 1.5 to 2 hours and allowed to cool in a desiccator (silica gel), and transfer to an iodine flask. Dissolve it in 25 mL of water, add 2 g of potassium iodide and 10 mL of dilute sulfuric acid, and stopper the flask. Allow the mixture to stand for 10 minutes, add 100 mL of water, and titrate with the prepared sulfuric acid solution (Indicator method; or potentiometric titration: platinum electrode). In the indicator method, when the solution assumes a pale yellow color as the end point is approached, add 3 mL of starch TS. Continue the titration, until the blue color disappears. Perform a blank determination. Calculate the molarity factor.

Each mL of 0.1 mol/L sodium thiosulfate VS = 3.567 mg of KI

Note: This solution, if stored for a long period, should be restandardized.
**Standardization**—Proceed as directed for standardization under 0.5 mol/L sulfuric acid VS, but weigh accurately about 0.4 g of sodium carbonate (standard reagent), and dissolve in 50 mL of water.

Each mL of 0.25 mol/L sulfuric acid VS = 26.50 mg of Na₂CO₃

**Sulfuric Acid, 0.1 mol/L**
1000 mL of this solution contains 9.808 g of sulfuric acid (H₂SO₄: 98.08).

**Preparation**—Add slowly, under stirring, 6 mL of sulfuric acid to 1000 mL of water, allow to cool, and standardize the solution as follows:

**Standardization**—Proceed as directed for standardization under 0.5 mol/L sulfuric acid VS, but weigh accurately about 0.15 g of sodium carbonate (standard reagent), and dissolve in 50 mL of water.

Each mL of 0.1 mol/L sulfuric acid VS = 10.60 mg of Na₂CO₃

**Sulfuric Acid, 0.05 mol/L**
1000 mL of this solution contains 4.904 g of sulfuric acid (H₂SO₄: 98.08).

**Preparation**—Add slowly, under stirring, 3 mL of sulfuric acid to 1000 mL of water, allow to cool, and standardize the solution as follows:

**Standardization**—Proceed as directed for standardization under 0.5 mol/L sulfuric acid VS, but weigh accurately about 80 mg of sodium carbonate (standard reagent), and dissolve in 30 mL of water.

Each mL of 0.05 mol/L sulfuric acid VS = 5.300 mg of Na₂CO₃

**Sulfuric Acid, 0.025 mol/L**
1000 mL of this solution contains 2.4520 g of sulfuric acid (H₂SO₄: 98.08).

**Preparation**—Before use, dilute 0.05 mol/L sulfuric acid VS with water to make exactly twice the initial volume.

**Sulfuric Acid, 0.01 mol/L**
1000 mL of this solution contains 0.9808 g of sulfuric acid (H₂SO₄: 98.08).

**Preparation**—Before use, dilute 0.05 mol/L sulfuric acid VS with water to make exactly 5 times the initial volume.

**Sulfuric Acid, 0.005 mol/L**
1000 mL of this solution contains 0.4904 g of sulfuric acid (H₂SO₄: 98.08).

**Preparation**—Before use, dilute 0.05 mol/L sulfuric acid VS with water to make exactly 10 times the initial volume.

**Sulfuric Acid, 0.0005 mol/L**
1000 mL of this solution contains 0.04904 g of sulfuric acid (H₂SO₄: 98.08).

**Preparation**—Before use, dilute 0.05 mol/L sulfuric acid VS with water to make exactly 100 times the initial volume.

**Tetraethylammonium Hydroxide, 0.1 mol/L**
1000 mL of this solution contains 25.947 g of tetrabutyl ammonium hydroxide [C₄H₉]₄NOH: 259.47.

**Preparation**—Before use, dilute a volume of 10% tetrabutylammonium hydroxide-methanol TS, equivalent to 26.0 g of tetrabutylammonium hydroxide, with 2-propanol to make 1000 mL, and standardize the solution as follows:

**Standardization**—Weigh accurately about 0.3 g of benzoic acid, previously dried in a desiccator (silica gel) for 24 hours, dissolve it in 50 mL of acetone, and titrate ≤0.5 ml the solution with the prepared tetrabutylammonium hydroxide solution (potentiometric titration). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L tetrabutylammonium hydroxide VS = 12.21 mg of C₆H₅COOH

Note: Store in tightly stoppered bottles. This solution, if stored for a long period, should be restandardized.

**Tetraethylammonium Hydroxide, 0.2 mol/L**
1000 mL of this solution contains 18.231 g of tetrethylammonium hydroxide [C₄H₉]₄NOH: 91.15.

**Preparation**—Before use, dilute a volume of tetrethylammonium hydroxide-methanol TS, equivalent to 18.4 g of tetrethylammonium hydroxide, with water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Weigh accurately about 0.4 g of benzoic acid, previously dried in a desiccator (silica gel) for 24 hours, dissolve it in 60 mL of N,N-dimethylformamide, and titrate ≤0.5 ml the solution with the prepared 0.2 mol/L tetrethyl ammonium hydroxide solution (Indicator method: 3 drops of thymol blue-N,N-dimethylformamide TS; or potentiometric titration). In the indicator method, titrate until a blue color is produced. Perform a blank determination in the same manner. Calculate the molarity factor.

Each mL of 0.2 mol/L tetrethylammonium hydroxide VS = 24.42 mg of C₆H₅COOH

Note: Store in tightly stoppered bottles. This solution, if stored for a long period, should be restandardized.

**Tetraethylammonium Hydroxide, 0.1 mol/L**
1000 mL of this solution contains 9.115 g of tetrethylammonium hydroxide [C₄H₉]₄NOH: 91.15.

**Preparation**—Before use, dilute a volume of tetrethylammonium hydroxide-methanol TS, equivalent to 9.2 g of tetrethylammonium hydroxide, with water to make 1000 mL, and standardize the solution as follows:

**Standardization**—Weigh accurately about 0.2 g of benzoic acid, previously dried in a desiccator (silica gel) for 24 hours, dissolve it in 30 mL of N,N-dimethylformamide and titrate ≤0.5 ml the solution with the prepared 0.1 mol/L tetrethyl ammonium hydroxide solution (Indicator method: 3 drops of thymol blue-N,N-dimethylformamide TS; or potentiometric titration). In the indicator method, titrate until a blue color is produced. Perform a blank determination in the same manner. Calculate the molarity factor.

Each mL of 0.1 mol/L tetrethylammonium hydroxide VS = 12.21 mg of C₆H₅COOH

Note: Store in tightly stoppered bottles. This solution, if stored for a long period, should be restandardized.

**Tetraethylammonium Hydroxide, 0.02 mol/L**
1000 mL of this solution contains 1.8231 g of tetrethylammonium hydroxide [C₄H₉]₄NOH: 91.15.

**Preparation**—Before use, dilute 0.1 mol/L tetrethylammonium hydroxide VS with freshly boiled and cooled water to make exactly 5 times the initial volume.
Tetramethylammonium Hydroxide-Methanol, 0.1 mol/L
1000 mL of this solution contains 15.425 g of tetramethylammonium hydroxide [(CH₃)₄NOH: 91.15].

Preparation—Before use, dilute a volume of tetramethylammonium hydroxide-methanol TS, equivalent to 9.2 g of tetramethylammonium hydroxide, with methanol to make 1000 mL, and standardize the solution as follows:

Standardization—Proceed as directed for standardization under 0.1 mol/L tetramethylammonium hydroxide VS.

Note: Store in tightly stoppered bottles. This solution, if stored for a long period, should be restandardized.

Titanium (III) Chloride, 0.1 mol/L
1000 mL of this solution contains 15.425 g of titanium (III) chloride (TiCl₃: 154.23).

Preparation—Add 75 mL of hydrochloric acid to 75 mL of titanium (III) chloride (20), and dilute with freshly boiled and cooled water to make 1000 mL. Transfer the solution into a buret provided with a reservoir protected from light, replace the air with hydrogen, and allow to stand for 48 hours. Before use, standardize the solution as follows:

Standardization—Weigh 3 g of ammonium iron (II) sulfate hexahydrate in a wide-mouthed, 500 mL conical flask. Passing carbon dioxide through the flask, dissolve it in 50 mL of freshly boiled and cooled water, and add 25 mL of diluted sulfuric acid (27 in 100). Rapidly add exactly 40 mL of 0.02 mol/L potassium permanganate VS to the mixture, while passing carbon dioxide through the flask. Titrate <2.50> with the prepared titanium (III) chloride solution until the calculated end point is approached, then add 5 g of ammonium thiocyanate immediately, and continue the titration with the prepared titanium (III) chloride solution until the color of the solution disappears. Perform a blank determination. Calculate the molarity factor.

Note: Store after the air has been displaced with hydrogen.

Titanium Trichloride, 0.1 mol/L
See Titanium (III) Chloride, 0.1 mol/L.

Zinc, 0.1 mol/L
1000 mL of this solution contains 6.538 g of zinc (Zn: 65.38).

Preparation—To 6.538 g of zinc (standard reagent), previously washed with dilute hydrochloric acid, with water and then acetone, and cooled in a desiccator (silica gel) after drying at 110°C for 5 minutes, add 80 mL of dilute hydrochloric acid and 2.5 mL of bromine TS, dissolve by gentle warming, evaporate excess bromine by boiling, and add water to make exactly 1000 mL.

Zinc Acetate, 0.05 mol/L
1000 mL of this solution contains 10.975 g of zinc acetate dihydrate [Zn(CH₃COO)₂·2H₂O: 219.50].

Preparation—Dissolve 11.1 g of zinc acetate dihydrate in 40 mL of water and 4 mL of dilute acetic acid, add water to make 1000 mL, and standardize the solution as follows:

Standardization—Measure exactly 20 mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS, and add 50 mL of water, 3 mL of ammonia-ammonium chloride buffer solution, pH 10.7, and 0.04 g of eriochrome black T-sodium chloride reagent. Titrate <2.50> the solution with the prepared zinc acetate solution until the blue color changes to blue-purple. Calculate the molarity factor.

Zinc Acetate, 0.02 mol/L
1000 mL of this solution contains 4.390 g of zinc acetate dihydrate [Zn(CH₃COO)₂·2H₂O: 219.50].

Preparation—Dissolve 4.43 g of zinc acetate dihydrate in 20 mL of water and 2 mL of dilute acetic acid, add water to make 1000 mL, and standardize the solution as follows:

Standardization—Proceed as directed for standardization under 0.05 mol/L zinc acetate VS, but measure exactly 20 mL of 0.02 mol/L disodium dihydrogen ethylenediamine tetraacetate VS.

Zinc Sulfate, 0.1 mol/L
1000 mL of this solution contains 28.755 g of zinc sulfate heptahydrate (ZnSO₄·7H₂O: 287.55).

Preparation—Dissolve 28.8 g of zinc sulfate heptahydrate in water to make 1000 mL, and standardize the solution as follows:

Standardization—Pipet 25 mL of the prepared zinc sulfate solution, add 5 mL of ammonia-ammonium chloride buffer solution, pH 10.7, and 0.04 g of eriochrome black T-sodium chloride indicator, and titrate <2.50> with 0.1 mol/L disodium dihydrogen ethylenediamine tetraacetate VS until the color of the solution changes from red-purple to blue-purple. Calculate the molarity factor.

Zinc sulfate, 0.02 mol/L
1000 mL of this solution contains 5.7510 g of zinc sulfate heptahydrate (ZnSO₄·7H₂O: 287.55).

Preparation—Before use, dilute 0.1 mol/L zinc sulfate VS with water to make exactly 5 times the initial volume.

9.22 Standard Solutions

Standard Solutions are used as the standard for the comparison in a text of the Pharmacopoeia.

Borate pH Standard Solution See pH Determination <2.54>.

Calcium Hydroxide pH Standard Solution See pH Determination <2.54>.

Carbonate pH Standard Solution See pH Determination <2.54>.

Formalin stock suspension To 25 mL of hexamethylenetetramine TS add 25 mL of hydrazinium sulfate TS, mix, and use after allowing to stand at 25 ± 3°C for 24 hours. Store in a glass container free from surface defects. Use within 2 months. Shake thoroughly before use.

Oxalate pH Standard Solution See pH Determination <2.54>.

pH Standard Solution, Borate See pH Determination <2.54>.

pH Standard Solution, Calcium Hydroxide See pH Determination <2.54>.

pH Standard Solution, Carbonate See pH Determination <2.54>.

pH Standard Solution, Oxalate See pH Determination <2.54>.
JP XVI

General Tests / 9.22 Standard Solutions 165

<pH Standard Solution, Phosphate</p>
See pH Determination 2.54.

<pH Standard Solution, Phthalate</p>
See pH Determination 2.54.

Phosphate pH Standard Solution
See pH Determination 2.54.

Phthalate pH Standard Solution
See pH Determination 2.54.

Standard Aluminum Stock Solution
Weigh 1.0 g of aluminum, add 60 mL of dilute hydrochloric acid (1 in 2), dissolve by heating, cool, add water to make exactly 1000 mL. Each mL of this solution contains 0.2698 mg of aluminum (Al).

Standard Ammonium Solution
Dissolve 2.97 g of ammonium chloride, exactly weighed, in water for ammonium limit test to make exactly 1000 mL. Each mL of this solution contains 0.01 mg of ammonium (NH₄⁺).

Standard Arsenic Solution
See Arsenic Limit Test 1.11.

Standard Arsenic Stock Solution
See Arsenic Limit Test 1.11.

Standard Boron Solution
Weigh exactly 0.286 g of boric acid, previously dried in a desiccator (silica gel) to constant mass, and dissolve in water to make exactly 1000 mL. Each mL of this solution contains 0.5 μg of boron (B).

Standard Cadmium Solution
Measure exactly 4.840 g of standard cadmium stock solution, and add diluted nitric acid (1 in 3) to make exactly 1000 mL. Each mL of this solution contains 0.001 mg of cadmium (Cd). Prepare before use.

Standard Cadmium Stock Solution
Dissolve 1.000 g of cadmium ground metal, exactly weighed, in 100 mL of dilute nitric acid by gentle heating, cool, and add dilute nitric acid to make exactly 1000 mL.

Standard Calcium Solution
Weigh exactly 0.250 g of calcium carbonate, add 5 mL of dilute hydrochloric acid and 25 mL of water, and dissolve by heating. After cooling, add water to make exactly 1000 mL. Each mL of this solution contains 0.1 mg of calcium (Ca).

Standard Calcium Solution for Atomic Absorption Spectrophotometry
Weigh accurately 0.250 g of calcium carbonate, and add 1 mol/L hydrochloric acid TS to make exactly 1000 mL. Each mL of this solution contains 1.00 mg of calcium (Ca).

Standard Copper Solution
Weigh exactly 1.000 g of copper (standard reagent), add 100 mL of dilute nitric acid, and dissolve by heating. After cooling, add water to make exactly 1000 mL.

Standard Copper Stock Solution
Weigh exactly 1.000 g of copper (standard reagent), add 100 mL of dilute nitric acid, and dissolve by heating. After cooling, add water to make exactly 1000 mL.

Standard Cyanide Solution
Measure exactly a volume of standard cyanide solution, equivalent to 10 mg of cyanide (CN), add 100 mL of potassium hydroxide TS and water to make exactly 1000 mL. Each mL of this solution contains 0.01 mg of cyanide (CN). Prepare before use.

Standard Cyanide Stock Solution
Dissolve exactly 4.840 g of potassium cyanide in water to make exactly 1000 mL. Measure exactly 100 mL of this solution, add 0.5 mL of 4-dimethylaminobenzylidene rhodanine TS, and titrate 2.50 with 0.01 mol/L silver nitrate VS until the solution shows a red color.

Each mL of 0.1 mol/L silver nitrate VS
= 5.204 mg of CN

Standard Fluorine Solution
See Oxygen Flask Combustion Method 1.00.

Standard Gold Solution for Atomic Absorption Spectrophotometry
To exactly 25 mL of standard gold solution, exactly measured, add water to make exactly 1000 mL. Each mL of this solution contains 0.025 mg of gold (Au).

Standard Gold Stock Solution
Dissolve exactly 10 mL of standard gold solution, and add water to make exactly 200 mL. Prepare before use. Each mL of this solution contains 0.250 mg of iron (Fe).

Standard Iron Solution
Dissolve exactly 10 mL of standard iron solution, and add water to make exactly 200 mL. Prepare before use. Each mL of this solution contains 0.01 mg of iron (Fe).

Standard Lead Solution
Measure exactly 10 mL of standard lead solution, and add water to make exactly 100 mL. Each mL of this solution contains 0.01 mg of lead (Pb). Prepare before use.
Standard Lead Stock Solution  Weigh exactly 159.8 mg of lead (II) nitrate, dissolve in 10 mL of dilute nitric acid, and add water to make exactly 1000 mL. Prepare and store this solution using glass containers, free from soluble lead salts.

Standard Liquids for Calibrating Viscosimeters [JIS, Standard Liquids for Calibrating Viscosimeters (Z 8809)]

Standard Magnesium Solution for Atomic Absorption Spectrophotometry  To exactly 1 mL of Standard Magnesium Stock Solution add water to make exactly 100 mL. Prepare before use. Each mL of this solution contains 0.0100 mg of magnesium (Mg).

Standard Magnesium Stock Solution  Dissolve exactly 8.365 g of magnesium chloride hexahydrate in 2 mol/L hydrochloric acid TS to make exactly 1000 mL.

Standard Mercury Solution  Weigh exactly 13.5 mg of mercury (II) chloride, previously dried for 6 hours in a desiccator (silica gel), dissolve in 10 mL of dilute nitric acid, and add water to make exactly 1000 mL. Pipet 10 mL of this solution, and add 10 mL of dilute nitric acid and water to make exactly 1000 mL. Each mL of this solution contains 0.1 μg of mercury (Hg). Prepare before use.

Standard Methanol Solution  See Methanol Test <1.12>.

Standard Nickel Solution  Dissolve 6.73 g of ammonium nickel (II) sulfate hexahydrate, exactly weighed, in water to make exactly 1000 mL. Pipet 5 mL of this solution, add water to make exactly 1000 mL. Each mL of this solution contains 0.005 mg of nickel (Ni).

Standard Nitric Acid Solution  Measure exactly 72.2 mg of potassium nitrate, dissolve in water to make exactly 1000 mL. Each mL of this solution contains 0.01 mg of nitrogen (N).

Standard Phosphoric Acid Solution  Weigh exactly 0.358 g of potassium dihydrogen phosphate, previously dried to constant mass in a desiccator (silica gel), and add 10 mL of dilute sulfuric acid (3 in 10) and water to make exactly 1000 mL. Pipet 10 mL of this solution, and add water to make exactly 1000 mL. Each mL of this solution contains 0.025 mg of phosphoric acid (as PO₄).

Standard Potassium Stock Solution  Weigh exactly 9.534 g of potassium chloride, previously dried at 130°C for 2 hours, and dissolve in water to make exactly 1000 mL. Each mL of this solution contains 5.00 mg of potassium (K).

Standard Selenium Solution  To exactly 1 mL of Standard Selenium Stock Solution add water to make exactly 1000 mL. Prepare before use. It contains 1.0 μg of selenium (Se) per mL.

Standard Selenium Stock Solution  Dissolve exactly 1.405 g of selenium dioxide in 0.1 mol/L nitric acid to make exactly 1000 mL.

Standard Silver Solution for Atomic Absorption Spectrophotometry  Measure exactly 10 mL of Standard Silver Stock Solution, and add water to make exactly 1000 mL. Each mL of this solution contains 0.01 mg of silver (Ag). Prepare before use.

Standard Silver Stock Solution  Dissolve 1.575 g of silver nitrate, exactly weighed, in water to make exactly 1000 mL. Each mL of this solution contains 1.00 mg of silver (Ag).

Standard Sodium Dodecylbenzene Sulfonate Solution  Weigh exactly 1.000 g of sodium dodecylbenzene sulfonate, and dissolve in water to make exactly 1000 mL. Pipet 10 mL of this solution, and add water to make exactly 1000 mL. Each mL of this solution contains 0.01 mg of sodium dodecylbenzene sulfonate [CH₃(CH₂)₁₄C₆H₄SO₃Na].

Standard Sodium Stock Solution  Weigh exactly 2.542 g of sodium chloride (standard reagent), previously dried at 130°C for 2 hours, and dissolve in water to make exactly 1000 mL. Each mL of this solution contains 1.00 mg of sodium (Na).

Standard Tin Solution  Weigh exactly 0.250 g of tin, and dissolve in 10 mL of sulfuric acid by heating. After cooling, transfer this solution with 400 mL of diluted hydrochloric acid (1 in 5) to a 500-mL volumetric flask, and add diluted hydrochloric acid (1 in 5) to make 500 mL. Pipet 10 mL of this solution, and add diluted hydrochloric acid (1 in 5) to make exactly 1000 mL. Each mL of this solution contains 0.005 mg of tin (Sn). Prepare before use.

Standard Vinyl Chloride Solution  Transfer about 190 mL of ethanol for gas chromatography into a 200-mL volumetric flask, and stopper with a silicone rubber stopper. Cooling this volumetric flask in a methanol-dry ice bath, inject 0.20 g of vinyl chloride, previously liquidized, through the silicone rubber stopper, and then inject ethanol for gas chromatography, previously cooled in a methanol-dry ice bath, through the silicone rubber stopper to make 200 mL. Pipet 1 mL of this solution, add ethanol for gas chromatography, cooled previously in a methanol-dry ice bath to make exactly 100 mL. Preserve in a hermetic container, at a temperature not exceeding –20°C. This solution contains 10 μg of vinyl chloride per mL.

Standard Water-Methanol Solution  See Water Determination <2.48>.

Standard Zinc Solution  Measure exactly 25 mL of Standard Zinc Stock Solution, and add water to make exactly 1000 mL. Prepare before use. Each mL of this solution contains 0.025 mg of zinc (Zn).

Standard Zinc Solution for Atomic Absorption Spectrophotometry  See Test for Rubber Closure for Aqueous Infusions <7.03>.

Standard Zinc Stock Solution  Dissolve exactly 1.000 g of zinc (standard reagent), in 100 mL of water and 5 mL of hydrochloric acid with the aid of gentle heating, cool, and add water to make exactly 1000 mL.

9.23 Matching Fluids for Color

Matching Fluids for Color are used as the reference for the comparison of color in a text of the Pharmacopoeia. They are prepared from the following colorimetric stock solutions. Colorimetric stock solutions are prepared by the following procedures and stored in glass-stoppered bottles. When the color of the solution is compared with Matching Fluids for Color, unless otherwise specified, transfer both

solutions and fluids to Nessler tubes and view transversely against a white background.

**Cobalt (II) Chloride CS** Weigh 65 g of cobalt (II) chloride hexahydrate, and dissolve in 25 mL of hydrochloric acid and water to make 1000 mL. Measure exactly 10 mL of this solution, and add water to make exactly 250 mL. Measure exactly 25 mL of the solution, add 75 mL of water and 0.05 g of mulexide–sodium chloride indicator, and add dropwise diluted ammonia solution (28) (1 in 10) until the color of the solution changes from green to purple. Titrate $2.50\%$ with 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate VS until the color of the solution changes from red-purple to yellow. Titrate $2.50\%$ with 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate VS until the color of the solution changes from green to purple.

Each mL of 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate

$$= 2.379 \text{ mg of CoCl}_2 \cdot 6\text{H}_2\text{O}$$

According to the titrated value, add diluted hydrochloric acid (1 in 40) to make a solution containing 62.4 mg of cobalt (II) chloride hexahydrate ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}: 237.93$) in each mL, and use this solution as the colorimetric stock solution.

**Cobaltous Chloride CS** See Cobalt (II) Chloride CS.

**Copper (II) Sulfate CS** Weigh 65 g of copper (II) sulfate pentahydrate, and dissolve in 25 mL of hydrochloric acid and water to make 1000 mL. Measure exactly 10 mL of this solution, and add water to make exactly 250 mL. Measure exactly 25 mL of the solution, add 75 mL of water, 10 mL of a solution of ammonium chloride (3 in 50), 2 mL of diluted ammonia solution (28) (1 in 10) and 0.05 g of mulexide–sodium chloride indicator. Titrate $2.50\%$ with 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate VS until the color of the solution changes from green to purple.

Each mL of 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate

$$= 2.497 \text{ mg of CuSO}_4 \cdot 5\text{H}_2\text{O}$$

According to the titrated value, add diluted hydrochloric acid (1 in 40) to make a solution containing 62.4 mg of copper (II) sulfate pentahydrate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}: 249.69$) in each mL, and use this solution as the colorimetric stock solution.

**Copper Sulfate CS** See Copper (II) Sulfate CS.

**Iron (III) Chloride CS** Weigh 55 g of iron (III) chloride hexahydrate, and dissolve in 25 mL of hydrochloric acid and water to make 1000 mL. Measure exactly 10 mL of this solution, transfer to an iodine flask, add 15 mL of water and 3 g of potassium iodide, stopper tightly, and allow to stand in a dark place for 15 minutes. Add 100 mL of water to the mixture, and titrate $2.50\%$ the liberated iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS).

Each mL of 0.1 mol/L sodium thiosulfate VS

$$= 27.03 \text{ mg of FeCl}_3 \cdot 6\text{H}_2\text{O}$$

According to the titrated value, add diluted hydrochloric acid (1 in 40) to make a solution containing 45.0 mg of iron (II) chloride hexahydrate ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}: 270.30$) in each mL, and use this solution as the colorimetric stock solution.

**Matching Fluids for Color** Measure exactly the volume of colorimetric stock solutions and water shown in the following table with a buret or a pipet graduated to less than 0.1 mL, and mix.

### Reagents, Test Solutions, etc.

**9.41 Reagents, Test Solutions**

Reagents are the substances used in the tests of the Pharmacopoeia. The reagents that are described as “Standard reagent for volumetric analysis”, “Special class”, “First class”, “For water determination”, etc. in square brackets meet the corresponding requirements of the Japan Industrial Standards (JIS). The tests for them are performed according to the test methods of JIS. In the case where the reagent name in the Pharmacopoeia differs from that of JIS, the JIS name is given in the brackets. The reagents for which a monograph’s title is given in the brackets meet the requirements of the corresponding monograph. In the case of the reagents that are described merely as test items, the corresponding test method of the Pharmacopoeia is applied.

Test Solutions are the solutions prepared for use in the tests of the Pharmacopoeia.

**Acemetacin** $\text{C}_{21}\text{H}_{18}\text{ClNO}_6$ [Same as the namesake monograph]

**Acemetacin for assay** $\text{C}_{21}\text{H}_{18}\text{ClNO}_6$ [Same as the monograph Acemetacin. When dried, it contains not less than 99.5% of acemetacin ($\text{C}_{21}\text{H}_{18}\text{ClNO}_6$) meeting the following additional specifications.]

**Purity** Related substances—Dissolve 40 mg of acemetacin for assay in 10 mL of methanol, and use this solution as
the sample solution. Pipet 1 mL of this solution, and add methanol to make exactly 10 mL. Pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.02> according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the area of each peak other than acemetacin obtained from the sample solution is not larger than 1/2 times the peak area of acemetacin obtained from the standard solution, and the total area of the peaks other than the peak of acemetacin is not larger than the peak area of acemetacin from the standard solution.

Operating conditions
Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay under Acemetacin Tablets.

Time span of measurement: About 4 times as long as the retention time of Acemetacin.

System Suitability Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of acemetacin obtained from 10 μL of this solution is equivalent to 3 to 7% of that of acemetacin from 10 μL of the standard solution.

System performance: Dissolve 75 mg of acemetacin and 75 mg of indometacin in 50 mL of methanol. To 4 mL of this solution add 1 mL of a solution of hexyl parahydroxybenzoate in methanol (1 in 250), and add methanol to make 50 mL. When the procedure is run with 10 μL of this solution under the above operating conditions, acemetacin, indometacin and hexyl parahydroxybenzoate are eluted in this order with the resolutions between the peaks of acemetacin and indometacin and between the peaks of indometacin and hexyl parahydroxybenzoate being not less than 3, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of acemetacin is not more than 1.5%.

Acenaphthene C_{12}H_{10} White to pale yellowish white crystals or crystalline powder, having a characteristic aroma. Freely soluble in diethyl ether and in chloroform, soluble in acetone, sparingly soluble in methanol, and practically insoluble in water.

Identification—Determine the infrared absorption spectrum of acenaphthene according to the paste method under Infrared Spectrophotometry <2.25>, with 5 mg of acenaphthene: it exhibits absorption at the wave numbers of about 1605 cm\(^{-1}\), 840 cm\(^{-1}\), 785 cm\(^{-1}\) and 750 cm\(^{-1}\).

Melting point <2.60>: 93 – 96°C

Purity—Dissolve 0.1 g of acenaphthene in 5 mL of chloroform, and use this solution as the sample solution. Perform the test with 2 μL of the sample solution as directed under Gas Chromatography <2.02> according to the following conditions. Measure each peak area by the automatic integration method, and calculate the amount of acenaphthene by the area percentage method: it shows a purity of not less than 98.0%.

Operating conditions
Detector: Hydrogen flame-ionization detector.

Acenaphthene is equivalent to 3 to 7% insoluble in water. Freely soluble in diethyl ether and in chloroform, soluble in crystals or crystalline powder, having a characteristic aroma.

1605 cm\(^{-1}\); it exhibits absorption at the wave numbers of about 168168 cm\(^{-1}\). The time span of measurement: About 4 times as long as the retention time of acenaphthene beginning after the solvent peak.

Residue on ignition <2.44>—Not more than 0.1% (1 g).

Acetal C_2H_4O_2 A clear and colorless volatile liquid. Miscible with water and with ethanol (95).

Refractive index <2.45> n_D\(^20\): about 1.382

Specific gravity <2.56> d_D\(^20\): about 0.824

Boiling point <2.57>: about 103°C

Acetaldehyde CH_3CHO [K 8030, First class]

Acetaldehyde for assay Distil 100 mL of acetaldehyde under reduced pressure, discard the first 20 mL of the distillate, and use the subsequent. Prepare before use.

Acetaldehyde for gas chromatography C_2H_4O A clear and colorless, flammable liquid. Miscible with water and with ethanol (95).

Refractive index <2.45> n_D\(^20\): about 1.332

Specific gravity <2.56> d_D\(^20\): about 0.788

Boiling point <2.57>: about 21°C

2-Acetamidoglutarimide C_{10}H_{18}N_2O_3: 170.17

Identification—Determine the infrared absorption spectrum of 2-acetamidoglutarimide as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>; it exhibits absorption at the wave numbers of about 3350 cm\(^{-1}\), 1707 cm\(^{-1}\), 1639 cm\(^{-1}\) and 1545 cm\(^{-1}\).

Purity Related substances—Dissolve 10 mg of 2-acetamidoglutarimide in 100 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Proceed with exactly 20 μL each of the sample solution and standard solution as directed in the Purity (3) under Acetoglutarimide Aluminiun: the total of the peak areas other than 2-acetamidoglutarimide from the sample solution is not larger than the peak area from the standard solution.

Content: not less than 98.0%. Assay—Weigh accurately about 20 mg of 2-acetamidoglutarimide, and perform the test as directed under Nitrogen Determination <1.08>.

Each mL of 0.005 mol/L sulfuric acid VS = 0.8509 mg of C_6H_8N_2O_3

Acetaminophen C_{6}H_{8}NO [Same as the namesake monograph]

Acetanilide C_8H_9NO White, crystals or crystalline powder.

Melting point <2.60>: 114 – 117°C
**p-Acetanisidine** \(C_9H_{11}NO_2\) White to purplish white, crystals or crystalline powder, having a characteristic odor. It is freely soluble in ethanol (95) and in acetonitrile, and very slightly soluble in water.

**Melting point** 2.050\(^{\circ}\) 126 – 132\(^{\circ}\)

**Content:** not less than 98.0%. Assay—Dissolve 0.1 g of \(p\)-acetanisidine in 5 mL of ethanol (95). Perform the test with 2 mL of this solution as directed under Gas Chromatography \(< 2.02\) according to the following conditions, and determine the area of each peak by the automatic integration method.

\[
\text{Content (\%)} = \left(\frac{\text{Peak area of } p\text{-acetanisidine}}{\text{total of all peak areas}}\right) \times 100
\]

**Operating conditions**
- **Detector:** Hydrogen flame-ionization detector.
- **Column:** A glass tube 3 mm in inside diameter and 2 m in length, packed with acid-treated and silanized siliceous earth for gas chromatography coated with alkylene glycol phthalate ester for gas chromatography in 1% (177–250 µm in particle diameter).
- **Column temperature:** A constant temperature of about 210\(^{\circ}\).
- **Carrier gas:** Nitrogen.
- **Flow rate:** Adjust to a constant flow rate of between 30 and 50 mL per minute and so that the retention time of \(p\)-acetanisidine is between 11 and 14 minutes.
- **Time span of measurement:** About 3 times as long as the retention time of \(p\)-acetanisidine beginning after the solvent peak.

**Acetate buffer solution, pH 3.5** Dissolve 50 g of ammonium acetate in 100 mL of 6 mol/L hydrochloric acid TS, adjust to pH 3.5 with ammonia TS or 6 mol/L hydrochloric acid TS, if necessary, and add water to make 200 mL.

**Acetate buffer solution, pH 4.5** Dissolve 63 g of anhydrous sodium acetate in a suitable amount of water, add 90 mL of acetic acid (100) and water to make 1000 mL.

**0.01 mol/L Acetate buffer solution, pH 5.0** Dissolve 385 g of ammonium acetate in 900 mL of water, add acetic acid (31) to adjust the pH to 5.0, and then add water to make 1000 mL.

**Acetate buffer solution, pH 5.4** To 5.78 mL of acetic acid (100) add water to make 1000 mL (solution A). Dissolve 8.2 g of anhydrous sodium acetate in water to make 1000 mL (solution B). Mix 176 mL of the solution A and 824 mL of the solution B, and adjust, if necessary, the pH to 5.4 with the solution A or the solution B.

**Acetate buffer solution, pH 5.5** Dissolve 2.72 g of sodium acetate trihydrate in water to make 1000 mL, and adjust the pH to 5.5 with diluted acetic acid (100) (3 in 2500).

**Acetic acid** See acetic acid (31).

**Acetic acid-ammonium acetate buffer solution, pH 3.0** Add acetic acid (31) to ammonium acetate TS, and adjust the pH to 3.0.

**Acetic acid-ammonium acetate buffer solution, pH 4.5** Dissolve 77 g of ammonium acetate in about 200 mL of water, adjust the pH to 4.5 by adding acetic acid (100), and add water to make 1000 mL.

**Acetic acid-ammonium acetate buffer solution, pH 4.8** Dissolve 77 g of ammonium acetate in about 200 mL of water, and add 57 mL of acetic acid (100) and water to make 1000 mL.

**Acetic acid buffer solution containing 0.1% bovine serum albumin** Dissolve 0.1 g of bovine serum albumin in sodium acetate trihydrate solution (1 in 100) to make exactly 100 mL, and adjust the pH to 4.0 with 1 mol/L hydrochloric acid TS.

**Acetic acid, dilute** Dilute 6 g of acetic acid (100) with water to make 100 mL (1 mol/L).

**Acetic acid-potassium acetate buffer solution, pH 4.3** Dissolve 14 g of potassium acetate in 20.5 mL of acetic acid (100), and add water to make 1000 mL.

**Acetic acid-sodium acetate buffer solution, pH 4.0** Dissolve 5.44 g of sodium acetate trihydrate in 900 mL of water, adjust the pH 4.0 with acetic acid (100), and add water to make 1000 mL.

**0.05 mol/L Acetic acid-sodium acetate buffer solution, pH 4.0** To 3.0 g of acetic acid (100) add water to make 1000 mL. Adjust to pH 4.0 with a solution prepared by dissolving 3.4 g of sodium acetate trihydrate in water to make 500 mL.

**0.1 mol/L Acetic acid-sodium acetate buffer solution, pH 4.0** Dissolve 13.61 g of sodium acetate trihydrate in 900 mL of water, adjust the pH to 4.0 with acetic acid (100), and add water to make 1000 mL.

**Acetic acid-sodium acetate buffer solution, pH 4.5** To 80 mL of sodium acetate TS add 120 mL of dilute acetic acid and water to make 1000 mL.

**Acetic acid-sodium acetate buffer solution, pH 4.5, for iron limit test** Dissolve 75.4 mL of acetic acid (100) and 11 g of sodium acetate trihydrate in 1000 mL of water.

**Acetic acid-sodium acetate buffer solution, pH 4.7** Dissolve 27.2 g of sodium acetate trihydrate in 900 mL of water, adjust the pH to 4.7 by adding acetic acid (100) dropwise, and add water to make 1000 mL.

**Acetic acid-sodium acetate buffer solution, pH 5.0** To 140 mL of sodium acetate TS add 60 mL of dilute acetic acid.
and water to make 1000 mL.

1 mol/L Acetic acid-sodium acetate buffer solution, pH 5.0 To sodium acetate TS add dilute acetic acid, and adjust the pH to 5.0.

Acetic acid-sodium acetate buffer solution, pH 5.5 Dissolve 20 g of sodium acetate trihydrate in 80 mL of water, adjust the pH to 5.5 by adding acetic acid (100) dropwise, and add water to make 100 mL.

Acetic acid-sodium acetate TS Mix 17 mL of 1 mol/L sodium hydroxide VS with 40 mL of dilute acetic acid, and add water to make 100 mL.

Acetic acid-sodium acetate TS, pH 7.0 Dissolve 4.53 g of sodium acetate trihydrate in water to make 100 mL, and adjust the pH to 7.0 with diluted acetic acid (100) (1 in 50).

0.02 mol/L Acetic acid-sodium acetate TS Dissolve 2.74 g of sodium acetate trihydrate in a suitable amount of water, and add 2 mL of acetic acid (100) and water to make 1000 mL.

0.25 mol/L Acetic acid TS To 3 g of acetic acid (100) add water to make 200 mL.

6 mol/L Acetic acid TS Dilute 36 g of acetic acid (100) with water to make 100 mL.

Acetic acid (100) CH₃COOH [K 8355, Acetic Acid, Special class]

Acetic acid (100)-sulfuric acid TS To 5 mL of acetic acid (100) add cautiously 5 mL of sulfuric acid while cooling in an ice bath, and mix.

Acetic acid (31) Dilute 31.0 g of acetic acid (100) with water to make 100 mL (5 mol/L).

Acetic anhydride (CH₃CO)₂O [K 8886, Special class]

Acetic anhydride-pyridine TS Place 25 g of acetic anhydride in a 100 mL volumetric flask, add pyridine to make 100 mL, and mix well. Preserve in light-resistant containers, protected from air. This solution may be used even if it becomes colored during storage.

Acetone CH₃COCH₃ [K 8034, Special class]

Acetone for nonaqueous titration Add potassium permanganate to acetone in small portions, and shake. When the mixture keeps its purple color after standing for 2 to 3 days, distil, and dehydrate with freshly ignited anhydrous potassium carbonate. Distill by using a fractionating column under protection from moisture, and collect the fraction distilling at 56°C.

Acetone for purity of crude drug CH₃COCH₃ [K 8034, Acetone, Special class] Use acetone meeting the following additional specification. Evaporate 300.0 mL of acetone to be tested in vacuum at a temperature not higher than 40°C, add the acetone to make exactly 1 mL, and use this solution as the sample solution. Separately, dissolve 2.0 mg of γ-BHC in hexane for purity of crude drug to make exactly 100 mL. Pipet 1 mL of this solution, and add hexane for purity of crude drug to make exactly 100 mL. Further pipet 2 mL of this solution, add hexane for purity of crude drug to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 1 μL each of the sample solution and standard solution (1) as directed under Gas Chromatography C2.02< according to the following operating conditions, and determine each peak area by the automatic integration method: the total area of peaks other than the solvent peak from the sample solution is not larger than the peak area of γ-BHC starting from the beginning of the standard solution (1).

Operating conditions Proceed the operating conditions in the Purity (2) under Crude Drugs Test <5.01D except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add hexane for purity of crude drug to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of γ-BHC obtained from 1 μL of the standard solution (2) can be measured by the automatic integration method, and the peak height of γ-BHC from 1 μL of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About three times as long as the retention time of γ-BHC beginning after the solvent peak.

Acetonitrile CH₃CN [K 8032, Special class]

Acetonitrile for liquid chromatography CH₃CN Colorless and clear liquid. Mixable with water.

Purity Ultraviolet light absorbing substances—Determine the absorbances at the following wavelengths as directed under Ultraviolet-visible Spectrophotometry C2.24>, using water as the control; not more than 0.07 at 200 nm, not more than 0.046 at 210 nm, not more than 0.027 at 220 nm, not more than 0.014 at 230 nm and not more than 0.009 at 240 nm.

Acetric acid C₄H₄I₃NO₃ White powder.

Purity Related substances—Dissolve 60 mg of acetric acid in a solution of meglumine (3 in 1000) to make 100 mL. To 10 mL of this solution add water to make 100 mL, and use this solution as the sample solution. Proceed the test with 5 μL of the sample solution as directed in the Assay under Meglumine Sodium Amidotrizoate Injection: any peaks other than the principal peak are not observed.

Acetylace ton CH₃COCH₂COCH₃ [K 8027, Special class]

Acetylace ton TS Dissolve 150 g of ammonium acetate in a sufficient quantity of water, and add 3 mL of acetic acid (100), 2 mL of acetylace ton and water to make 1000 mL. Prepare before use.

Acetylene See dissolved acetylene.

Achyranthes root for thin-layer chromatography A heat-dried, pulverized root of Achyranthes fauriei Leveillé et Vaniot (Amaranthaceae) meeting the following additional specifications.

Identification (1) To 2 g of pulverized achyranthes root for thin-layer chromatography add 10 mL of water, shake for 10 minutes, add 5 mL of 1-butanol, shake for 10 minutes, centrifuge, and use the supernatant liquid as the sample solution. Separately, dissolve 1 mg of chikuset-
susaponin IV for thin-layer chromatography in 1 mL of methanol, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography $2.07$. Spot 10 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of ethyl acetate, water and formic acid (5:1:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly dilute sulfuric acid on the plate, and heat the plate at 105°C for 10 minutes: the standard solution shows a deep purplish red spot at around $R_f$ value of 0.35, and the sample solution shows spots equivalent to those described below:

<table>
<thead>
<tr>
<th>$R_f$ value</th>
<th>Color and shape of the spot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Around 0</td>
<td>A weak spot, black</td>
</tr>
<tr>
<td>Around 0.1</td>
<td>A weak, tailing spot, strong purplish red</td>
</tr>
<tr>
<td>Around 0.2</td>
<td>A strong spot, deep purplish red</td>
</tr>
<tr>
<td>Around 0.25</td>
<td>A leading spot, deep purplish red</td>
</tr>
<tr>
<td>Around 0.45</td>
<td>A weak spot, dull yellow</td>
</tr>
<tr>
<td>Around 0.5</td>
<td>A weak spot, grayish purplish red</td>
</tr>
<tr>
<td>Around 0.7</td>
<td>A weak spot, grayish red</td>
</tr>
<tr>
<td>Around 0.9</td>
<td>A weak spot, dull red</td>
</tr>
</tbody>
</table>

(2) Perform the test as directed in the operating conditions under (1), except using a mixture of 1-propanol, ethyl acetate and water (4:4:3) as the developing solvent: the standard solution shows a deep purplish red spot at around $R_f$ value of 0.45, and the sample solution shows spots equivalent to those described below:

<table>
<thead>
<tr>
<th>$R_f$ value</th>
<th>Color and shape of the spot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Around 0.25</td>
<td>A weak spot, strongly purplish red</td>
</tr>
<tr>
<td>Around 0.25 – 0.3</td>
<td>A leading spot or two strong spots, strongly purplish red</td>
</tr>
<tr>
<td>Around 0.35</td>
<td>A deep purplish red spot</td>

</tbody>
</table>

**Acidic ferric chloride TS** See iron (III) chloride TS, acidic.

**Acidic potassium chloride TS** See potassium chloride TS, acidic.

**Acidic potassium permanganate TS** See potassium permanganate TS, acidic.

**Acidic stannous chloride TS** See tin (II) chloride TS, acidic.

**Acid-treated gelatin** See gelatin, acid-treated.

**Aconitine for purity C$_{34}$H$_{47}$NO$_{11}$** White, crystals or crystalline powder. Slightly soluble in acetonitrile and in ethanol (99.5), slightly soluble in diethyl ether, and practically insoluble in water. Melting point: about 185°C (with decomposition).

**Identification**—Determine the infrared absorption spectrum of aconitine for purity as directed in the potassium bromide disk method under Infrared Spectrophotometry $2.25$: it exhibits absorption at the wave numbers of about 3500 cm$^{-1}$, 1718 cm$^{-1}$, 1278 cm$^{-1}$, 1111 cm$^{-1}$, 1097 cm$^{-1}$ and 717 cm$^{-1}$.

**Absorbance** $2.24$: $E_{10}$% (230 nm): 211 – 243 [5 mg dried for not less than 12 hours in a desiccator (reduced pressure not exceeding 0.67 kPa, phosphorus (V) oxide, 40°C), ethanol (99.5), 200 mL].

**Purity** Related substances—

(1) Dissolve 5.0 mg of aconitine for purity in 2 mL of acetonitrile, and use as the sample solution. Pipet 1 mL of the sample solution, add acetonitrile to make exactly 50 mL, and use as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography $2.07$. Spot 20 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography, and proceed the test as directed in the Identification in Processed Aconite Root: the spot other than the principal spot obtained with the sample solution is not more intense than the spot with the standard solution.

(2) Dissolve 5.0 mg of aconitine for purity in 5 mL of acetonitrile, and use as the sample solution. Pipet 1 mL of the sample solution, add acetonitrile to make exactly 50 mL, and use as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography $2.07$: according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than the peaks of aconitine and the solvent obtained with the sample solution is not larger than the peak area of aconitine with the standard solution.

**Operating conditions**

Detector, column, and column temperature: Proceed as directed in the operating conditions in the Purity under Processed Aconite Root.

Mobile phase: A mixture of phosphate buffer solution for processed aconite root and tetrahydrofuran (9:1).

Flow rate: Adjust the flow rate so that the retention time of aconitine is about 26 minutes.

Time span of measurement: About 3 times as long as the retention time of aconitine.

**System suitability**

Test for required detectability: Pipet 1 mL of the standard solution, and add acetonitrile to make exactly 20 mL. Confirm that the peak area of aconitine obtained from 10 μL of this solution is equivalent to 3.5 to 6.5 μL each of the sample solution and standard solution.

System performance: Dissolve 1 mg each of aconitine for purity, hypaconitine for purity and mesaconitine for purity, and 8 mg of jesaconitine for purity in 200 mL of acetonitrile. When the procedure is run with 10 μL of this solution under the above operating conditions, mesaconitine, hypaconitine, aconitine and jesaconitine are eluted in this order, and each resolution between these peaks is not less than 1.5, respectively.

**System repeatability:** When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of aconitine is not more than 1.5%.
Water \(<2.48\): not more than 1.0% [5 mg dried for not less than 12 hours in a desiccator (reduced pressure not exceeding 0.67 kPa, phosphorus (V) oxide, 40°C), coulometric titration].

Aconitum diester alkaloids standard TS for purity It is a solution containing 10 mg of aconitine for purity, 10 mg of jesaconitine for purity, 30 mg of hypaconitine for purity and 20 mg of mesaconitine for purity in 1000 mL of a mixture of water (95), and sparingly soluble in water.

Melting point \(<2.60\): 151 – 154°C

Content: not less than 98.0%. Assay—Weigh accurately about 1 g of adipic acid, and 100 mL of water, dissolve by warming, cool, and titrate \(<2.50\) with 1 mol/L sodium hydroxide VS (indicator: 2 drops of phenolphthalein TS).

Each mL of 1 mol/L sodium hydroxide VS = 73.07 mg of C\(_6\)H\(_{10}\)O\(_4\).

Agar [K 8263, Special class. Same as the monograph Agar or Agar Powder. Loss on drying is not more than 15%.

Agar medium, ordinary See ordinary agar medium.

Agar slant Dispense portions of about 10 mL of ordinary agar medium into test tubes, and sterilize by autoclaving. Before the medium congeals, allow to stand in a slanting position, and solidify. When the coagulating water is lost, reprepare by dissolving with the aid of heat.

Ajmaline for assay C\(_{20}\)H\(_{26}\)N\(_2\)O\(_2\). [Same as the monograph Ajmaline. When dried, it contains not less than 99.0% of ajmaline (C\(_{20}\)H\(_{26}\)N\(_2\)O\(_2\)).

Alacepril C\(_{20}\)H\(_{26}\)N\(_2\)O\(_5\)S [Same as the namesake monograph]

Alacepril for assay [Same as the monograph Alacepril. When dried, it contains not less than 99.0% of alacepril (C\(_{20}\)H\(_{26}\)N\(_2\)O\(_5\)S)].

\(\beta\)-Alanine C\(_6\)H\(_5\)NO\(_2\) Colorless crystals or a white crystalline powder. Freely soluble in water, very slightly soluble in methanol, and practically insoluble in ethanol (99.5) and in diethyl ether.

Purity Related substances—Dissolve 5.0 mg in 10 mL of diluted methanol (4 in 5), and use this as the sample solution. Pipet 1 mL of this solution, add diluted methanol (4 in 5) to make exactly 100 mL, and use this as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography \(<2.63\). Spot 2 \(\mu\)L each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of 1:butanol, water and acetic acid (100) (5:2:2) to a distance of about 8 cm, and air-dry the plate. Spray evenly a solution of ninhydrin in acetone (1 in 50) on the plate, and heat at 80°C for 5 minutes: the spot other than the principal spot obtained from the sample solution is not more intense than the spot from the standard solution.

L-Alanine C\(_6\)H\(_5\)NO\(_2\) [K 9101, Special class]

Albiflorin C\(_{23}\)H\(_{28}\)O\(_{11}\). White powder having no odor. Freely soluble in water, in methanol and in ethanol (99.5).

Identification—Determine the absorption spectrum of a solution of albiflorin in diluted methanol (1 in 2) (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry \(<2.24\): it exhibits a maximum between 230 nm and 234 nm.

Purity (1) Related substances 1—Dissolve 1 mg of albiflorin in 1 mL of methanol, and perform the test with 10 \(\mu\)L of this solution as directed in the Identification (2) under Peony Root: any spot other than the principal spot which appears at around Rf 0.2 does not appear.
(2) Related substances 2—Dissolve 1 mg of albiflorin in 10 mL of diluted methanol (1 in 2), and use this solution as the sample solution. Perform the test with 10 μL of the sample solution as directed in the Assay under Peony Root, and measure the peak areas about 2 times as long as the retention time of peoniflorin: the total area of the peaks other than albiflorin from the sample solution is not larger than 1/10 times the total area of the peaks other than the solvent peak.

Albumin TS Carefully separate the white from the yolk of a fresh hen’s egg. Shake the white with 100 mL of water until the mixture is thoroughly mixed, and filter. Prepare before use.

Alcian blue 8 GX C18H28Cl2CuN16S4 Dark blue-purple powder.

Alcian blue staining solution Dissolve 0.5 g of alcian blue 8 GX in 100 mL of diluted acetic acid (100) (3 in 100). White to pale yellow powder. Very soluble in methanol, practically insoluble in water.

Aldehyde dehydrogenase Each mg contains not less than 2 enzyme activity units. White powder.

Assay—Dissolve about 20 mg of aldehyde dehydrogenase, accurately weighed, in 1 mL of water, add ice-cold solution of bovine serum albumin (1 in 100) to make exactly 200 mL, and use this solution as the sample solution. In a spectrophotometric cell, place 2.50 mL of pyrophosphate buffer solution, pH 9.0, 0.20 mL of a solution prepared by dissolving 20.0 mg of β-nicotinamide adenine dinucleotide (NAD) to make exactly 1 mL, 0.10 mL of a pyrazole solution (17 in 2500) and 0.10 mL of the sample solution, stir, stopper tightly, determine every 30 seconds the absorbance at 340 nm as directed under Ultraviolet-visible Spectrophotometry <2.26>, and calculate a change (ΔA) in absorbance in minute starting from the spot where the relation of time and absorbance is shown with a straight line. One enzyme activity unit means an amount of enzyme which oxidizes 1 μmol of acetaldehyde per minute when the test is conducted under the conditions of the Procedure.

Enzyme activity unit (unit/mg) of aldehyde dehydrogenase

\[
\text{Enzyme activity unit (unit/mg) of aldehyde dehydrogenase} = \frac{2.91 \times \Delta A \times 200}{6.3 \times M \times 0.10 \times 1000}
\]

M: Amount (g) of sample

Aldehyde dehydrogenase TS Dissolve an amount equivalent to 70 aldehyde dehydrogenase units in 10 mL of water. Prepare before use.

Aldehyde-free ethanol See ethanol, aldehyde-free.

Alendronate sodium hydrate C13H12NNaO7.P2.3H2O [Same as the namesake monograph]

Alisol A for thin-layer chromatography C30H50O5 A white to pale yellow powder. Very soluble in methanol, freely soluble in ethanol (99.5), and practically insoluble in water.

Optical rotation <2.49> [α]D20: +86° – +106° (5 mg previously dried on silica gel for 24 hours, methanol, 1 mL, 50 mm).

Purity Related substances—Dissolve 1 mg in 1 mL of methanol. Proceed the test with 5 μL of this solution as directed in the Identification (6) under Saireito Extract: no spot appears other than the principal spot of around Rf 0.3.

Alizarin complexone C14H24N2O4 1,2-Dihydroxy-3-quinolone-2,4-naphthalene-N,N-diacetate A yellow-brown powder. Soluble in ammonia TS, and practically insoluble in water, in ethanol (95) and in diethl ether.

Sensitivity—Dissolve 0.1 g of alizarin complexone by adding 2 drops of ammonia solution (28), 2 drops of ammonium acetate TS and 20 mL of water. To 10 mL of this solution add acetic acid-potassium acetate buffer solution, pH 4.3, to make 100 mL. Place 1 drop of this solution on a white spot plate, add 1 drop of a solution of sodium fluoride (1 in 100,000) and 1 drop of cerium (III) nitrate hexahydrate TS, stir, and observe under scattered light after 1 minute: a blue-purple color is produced, and the color of the control solution is red-purple. Use a solution prepared in the same manner, to which 1 drop of water is added in place of a solution of sodium fluoride, as the control solution.

Alizarin complexone TS Dissolve 0.390 g of alizarin complexone in 20 mL of a freshly prepared solution of sodium hydroxide (1 in 50), then add 800 mL of water and 0.2 g of sodium acetate trihydrate, and dissolve. Adjust the pH to 4 to 5 with 1 mol/L hydrochloric acid VS, and add water to make 1000 mL.

Alizarin red S C13H12NaO7 [K 8057, Special class]

Alizarin red S TS Dissolve 0.1 g of alizarin red S in water to make 100 mL, and filter if necessary.

Alizarin S See alizarin red S.

Alizarin S TS See alizarin red S TS.

Alizarin yellow GG C13H12N4NaO7 [K 8056, Special class]

Alizarin yellow GG-thymolphthalein TS Mix 10 mL of alizarin GG TS with 20 mL of thymolphthalein TS.

Alizarin yellow GG TS Dissolve 0.1 g of alizarin yellow GG in 100 mL of ethanol (95), and filter if necessary.

Alkali copper TS Dissolve 70.6 g of disodium hydrogen phosphate dodecahydrate, 40.0 g of potassium sodium tartrate tetrahydrate and 180.0 g of anhydrous sodium sulfate in 600 mL of water, and add 20 mL of a solution of sodium hydroxide (1 in 5). To this mixture add, with stirring, 100 mL of a solution of copper (II) sulfate (2 in 25), 33.3 mL of 0.05 mol/L potassium iodate VS and water to make 1000 mL.

Alkali blue tetrazolium TS See blue tetrazolium TS, alkaline.

Alkaline copper solution See alkaline copper TS for protein content determination.

Alkali copper TS Dissolve 2 g of anhydrous sodium carbonate in 100 mL of 0.1 mol/L sodium hydroxide TS. To 50 mL of this solution add 1 mL of a mixture of a solution of copper (II) sulfate pentahydrate (1 in 100) and a solution of potassium tartrate (1 in 50) (1:1), and mix.

Alkaline copper TS for protein content determination Dissolve 0.8 g of sodium hydroxide in water to make 100 mL. Dissolve 4 g of anhydrous sodium carbonate in this solution to make solution A. Combine 1 mL of copper (II) sulfate pentahydrate solution (1 in 50) and 1 mL of sodium tar-
trate dihydrate solution (1 in 25) to make solution B. Mix 50 mL of solution A and 1 mL of solution B. Prepare at the time of use.

Alkaline copper (II) sulfate solution See copper (II) sulfate solution, alkaline.

Alkaline copper (II) TS Dissolve 20 g of anhydrous sodium carbonate in dilute sodium hydroxide TS to make 1000 mL, and use this solution as solution A. Dissolve 0.5 g of copper (II) sulfate pentahydrate in potassium sodium tartrate tetrahydrate solution (1 in 100) to make 100 mL, and use this solution as solution B. To 50 mL of solution A add 1 mL of solution B. Prepare before use.

Alkaline glycerin TS To 200 g of glycerin add water to make 235 g, and add 142.5 mL of sodium hydroxide TS and 47.5 mL of water.

Alkaline hydroxylamine TS See hydroxylamine TS, alkaline.

Alkaline m-dinitrobenzene TS See 1,3-dinitrobenzene TS, alkaline.

Alkaline phosphatase Obtained from bovine small intestine, a white to grayish white or yellow-brown, freeze-dried powder having no odor. Alkaline phosphatase contains not less than 1 unit per mg and no salts. One unit of alkaline phosphatase indicates an amount of the enzyme which produces 1 µmol of 4-nitrophenol in 1 minute at 37°C and pH 9.8, from 4-nitrophenylphosphate as the substrate.

Alkaline phosphatase TS Dissolve 0.1 g of alkaline phosphatase in 10 mL of boric acid-magnesium chloride buffer solution, pH 9.0. Prepare before use.

Alkaline picric acid TS See 2,4,6-trinitrophenol TS, alkaline.

Alkaline potassium ferricyanide TS See potassium hexacyanoferrate (III) TS, alkaline.

Alkylene glycol phthalate ester for gas chromatography Prepared for gas chromatography.

Allopurinol C7H7N3 White to light yellow crystals or crystalline powder, having a characteristic odor. Melting point: 232 – 238°C.

Amidosulfuric acid (standard reagent) HOSO2NH2 [K 8005, Standard substance for volumetric analysis]

Amidotrizoic acid for assay C11H9I3N2O4 Same as the monograph Amidotrizoic Acid. It contains not less than 99.9% of amidotrizoic acid (C11H9I3N2O4), calculated on the dried basis.

p-Aminoacetophenone See 4-aminoacetophenone.

p-Aminoacetophenone TS See 4-aminoacetophenone TS.

4-Aminoacetophenone H2NC6H4COCH3 Light yellow, crystals or crystalline powder, having a characteristic odor. Melting point <2.60º: 105 – 108°C

4-Aminoacetophenone TS Dissolve 0.100 g of 4-aminoacetophenone in methanol to make exactly 100 mL.

4-Aminoantipyrine C13H17NO2 [K 8048, Special class]

4-Aminoantipyrine hydrochloride TS Dissolve 1 g of 4-aminoantipyrine hydrochloride in 25 mL of water: the solution is almost clear.

Alternative thioglycolate medium See Sterility Test <4.06> under the General Tests, Processes and Apparatus.

Aluminon C22H23N3O4 [K 8011, Special class]

Aluminon TS Dissolve 0.1 g of aluminon in water to make 100 mL, and allow this solution to stand for 24 hours.

Aluminum (Al) [K 8069, Special class]

Aluminum chloride See aluminum (III) chloride hexahydrate.

Aluminum chloride TS See Aluminum (III) chloride TS.

Aluminum (III) chloride TS Dissolve 64.7 g of aluminum (III) chloride hexahydrate in 71 mL of water, add 0.5 g of activated charcoal, then shake for 10 minutes, and filter. Adjust the pH of the filtrate to 1.5 with a solution of sodium hydroxide (1 in 100) with stirring, and filter if necessary.

Aluminum (III) chloride hexahydrate AlCl₃.6H₂O [K 8114, Special class]

Aluminum oxide Al₂O₃ White crystals, crystalline powder, or powder. Boiling point: about 3000°C. Melting point: about 2000°C.

Aluminum potassium sulfate dodecahydrate AlK(SO₄)₂.12H₂O [K 8255, Special class]

6-Amidino-2-naphthyl methanesulfonate C₁₁H₁₀N₂O₆.CH₃SO₂H A white to pale yellow crystalline powder. Melting point: about 233°C (with decomposition).

Purity—A solution obtained by dissolving 0.5 g of 6-amidino-2-naphthyl methanesulfonate in 10 mL of methanol is clear.

Amidosulfuric acid (standard reagent) HOSO₂NH₂ [K 8005, Standard substance for volumetric analysis]

Amidotrizoic acid for assay C₁₁H₉I₃N₂O₄ Same as the monograph Amidotrizoic Acid. It contains not less than 99.9% of amidotrizoic acid (C₁₁H₉I₃N₂O₄), calculated on the dried basis.

p-Aminoacetophenone See 4-aminoacetophenone.

p-Aminoacetophenone TS See 4-aminoacetophenone TS.

4-Aminoacetophenone H₂NC₆H₄COCH₃ Light yellow, crystals or crystalline powder, having a characteristic odor. Melting point <2.60º: 105 – 108°C

4-Aminoacetophenone TS Dissolve 0.100 g of 4-aminoacetophenone in methanol to make exactly 100 mL.

4-Aminoantipyrine C₁₃H₁₇NO₂ [K 8048, Special class]

Purity Clarity of solution—Dissolve 1 g of 4-aminoantipyrine hydrochloride in 25 mL of water: the solution is almost clear.

Content: 100.6 – 108.5%. Assay—Weigh accurately about 0.5 g of 4-aminoantipyrine hydrochloride, dissolve in 50 mL of water, and, if necessary, neutralize with 0.1 mol/L sodium hydroxide VS (indicator: red litmus paper). Add 4 drops of dichlorofluorescein TS, and titrate <2.50º> with 0.1 mol/L silver nitrate VS.

Each mL of 0.1 mol/L silver nitrate VS = 23.97 mg of C₁₃H₁₇N₃O.HCl

4-Aminoantipyrine hydrochloride TS Dissolve 1 g of 4-aminoantipyrine hydrochloride in water to make 50 mL.

4-Aminoantipyrine TS Dissolve 0.1 g of 4-aminoantipyrine in 30 mL of water, add 10 mL of a solution of sodium carbonate decahydrate (1 in 5), 2 mL of sodium hydroxide TS and water to make 100 mL. Prepare before use.

2-Aminobenzimidazole C₇H₇N₁ White to light yellow
Aminobenzoate derivatization TS To 0.28 g of ethyl aminobenzoate add 600 μL of methanol, warm at about 50°C to dissolve, and add 170 μL of acetic acid and 145 μL of borane-pyridine complex.

p-Aminobenzoic acid See 4-aminobenzoic acid.

4-Aminobenzoic acid C₆H₄N₂COOH White to very pale yellow crystalline powder.

Purity Clarity of solution—Dissolve 0.1 g of 4-aminobenzoic acid in 10 mL of ethanol (95): the solution is clear.

2-Amino-1-butanol CH₃CH₂CH(NH₂)CH₂OH Clear, colorless to light yellow liquid. Miscible with water and dissolves in methanol.

Refractive index <2.45> nD²₀: 1.450 – 1.455

Specific gravity <2.56> dD²₀: 0.944 – 0.950

Purity Related substances—Dissolve 50 mg of 2-amino-1-butanol in 10 mL of methanol, measured exactly, and perform the test with 2 μL of this solution as directed in the Purity (4) under Ethambutol Hydrochloride: any spot other than the principal spot at the Rf value of about 0.3 does not appear.

4-Aminobutylglycine C₄H₁₁NO₃.HCl White crystals or crystalline powder. Melting point: about 200°C (with decomposition).

2-Amino-5-chlorobenzenophenone for thin-layer chromatography C₁₅H₁₂ClNO Yellow, crystalline powder.

Melting point <2.60>: 97 – 101°C

Purity Related substances—Dissolve 10 mg of 2-amino-5-chlorobenzenophenone for thin-layer chromatography in methanol to make exactly 200 mL, and perform the test with this solution as directed in the Purity (4) under Ethambutol Hydrochloride: any spot other than the principal spot at the Rf value about 0.7 does not appear.

4-Aminodiethylamine sulfate monohydrate C₆H₁₂N₂SO₄.H₂O White to slightly colored powder. It dissolves in water.

Melting point <2.60>: 173 – 176°C

Residue on ignition <2.44>: not more than 0.1% (1 g).

4-Amino-4-N,N-diethylaniline sulfate TS Dissolve 0.2 g of 4-amino-N,N-diethylaniline sulfate monohydrate in water to make 100 mL. Prepare before use, protected from light.

2-Aminoethylhydrochloride C₅H₁₀N₂SH.HCl White crystal or granule.

Melting point <2.60>: 65 – 71°C

2-Aminoethanol NH₂CH₂CH₂OH [K 8109, Special class]

N-Aminohexamethylenamine (CH₃)₆N≡N Cleared, colorless to pale yellow liquid.

Refractive index <2.45> nD²₀: 1.482 – 1.487

Specific gravity <2.56> dD²₀: 0.936 – 0.942

2-Amino-2-hydroxymethyl-1,3-propanediol C₆H₁₁NO₃ [K 9704, Special class]

2-Amino-2-hydroxymethyl-1,3-propanediol hydrochloride C₆H₁₁NO₃.HCl White crystals or crystalline powder

4-(Aminomethyl)benzoic acid C₈H₁₀NO₂ A white powder.

Purity—Dissolve 10 mg of 4-(aminomethyl)benzoic acid in 100 mL of water, and use this as the sample solution. Pipet 1 mL of the sample solution, add water to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL of each of the sample solution and standard solution as directed under Liquid Chromatography <2.0F> according to the operating conditions as directed in the Purity (5) under Tranexamic Acid, and determine each peak area by the automatic integration method: each of the peak other than 4-(aminomethyl)benzoic acid obtained from the sample solution is not larger than the peak area of 4-(aminomethyl)benzoic acid from the standard solution.

1-Amino-2-methylnaphthalene C₁₁H₁₁N Pale yellow to pale brown masses or liquid.

2-Aminomethylpyridine C₆H₁₄N A colorless or light yellowish clear liquid, having an amine like characteristic odor.

Identification—Determine the infrared absorption spectrum as directed in the liquid film method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3280 cm⁻¹, 1600 cm⁻¹, 1440 cm⁻¹, 1120 cm⁻¹ and 840 cm⁻¹.

Purity Related substances—Perform the test with 0.8 μL of 2-aminomethylpyridine as directed under Gas Chromatography <2.0E>. Determine each peak area by the automatic integration method, and calculate these amounts by the area percentage method: the total amount of the peaks other than 2-aminomethylpyridine is not more than 1.5%.

Operating conditions

Detector: A hydrogen flame-ionization detector.

Column: A glass column 3 mm in inside diameter and 2 m in length, packed with siliceous earth for gas chromatography (150 – 180 μm) coated with 10% of polyethylene glycol 20M for gas chromatography and 2% of potassium hydrogen oxide.

Column temperature: 100°C at beginning, and increase to 200°C by 10°C per minute after injection.

Carrier gas: Nitrogen.

Flow rate: Adjust the flow rate so that the retention time of 2-aminomethylpyridine is about 5 minutes.

Time span of measurement: About 2 times as long as the retention time of 2-aminomethylpyridine.

3-(2-Aminomethyl)indole C₅H₁₈N₂ Yellowish-brown crystals.

Melting point <2.60>: about 118°C.

1-Amino-2-naphthol-4-sulfonic acid C₁₀H₉NO₄S [K 8050, Special class]

1-Amino-2-naphthol-4-sulfonic acid TS Mix thoroughly 5 g of anhydrous sodium sulfate, 94.3 g of sodium bisulfite and 0.7 g of 1-amino-2-naphthol-4-sulfonic acid. Before use, dissolve 1.5 g of this mixture in water to make 10 mL.

m-Aminophenol See 3-aminophenol.

3-Aminophenol C₆H₄NH₂OH White, crystals or crystalline powder.

Melting point <2.60>: about 121 – 125°C

Content: not less than 97.0%. Assay—Weigh accurately about 0.2 g, dissolve in 50 mL of acetic acid for nonaqueous titration, and titrate <2.50> with 0.1 mol/L perchloric acid...
VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS
                   = 10.91 mg of H₂NCl₂H₂O

*p*-Aminophenol hydrochloride See 4-aminophenol hydrochloride.

4-Aminophenol hydrochloride  HOC₆H₄NH₂.HCl
White to pale colored crystals. Freely soluble in water and in ethanol (95). Melting point: about 306°C (with decomposition).

Content: not less than 99.0%. Assay—Weigh accurately about 0.17 g of 4-aminophenol hydrochloride, dissolve in 50 mL of acetic acid for nonaqueous titration and 5 mL of mercury (II) acetate TS for nonaqueous titration, and titrate ≤2.50 with 0.1 mol/L perchloric acid-1,4-dioxane VS (indicator: 1 mL of p-naphtholbenzeine TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid-1,4-dioxane VS
                   = 14.56 mg of C₆H₄NOC₁

Storage—Preserve in tight, light-resistant containers.

Aminopropylsilanized silica gel for pretreatment Prepared for pretreatment.

Aminopyrine  C₁₃H₁₇N₃O White to pale yellow crystals or crystalline powder. Odorless.

Melting point <2.60°: 107 – 109°C

6-Aminoquinolyl-N-hydroxysuccinimidyl carbamate
C₁₄H₁₁N₃O₄ Prepared for amino acid analysis or biochemistry.

1,2-Aminosuberic acid  C₄H₈NO₄ White, crystals or crystalline powder. Odorless.

Optical rotation <2.49° [α]D°: +19.1 – +20.1° (after drying, 0.1 g, 5 mol/L hydrochloric acid TS, 100 mm).

Loss on drying <2.47°: not more than 0.3% (1 g, 105°C, 2 hours).

Assay—Weigh accurately about 0.3 g of 1,2-aminosuberic acid, previously dried, add exactly 6 mL of formic acid to dissolve, then add exactly 50 mL of acetic acid (100), and titrate ≤2.50 with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS
                   = 18.92 mg of C₈H₁₅NO₄

Amiodarone hydrochloride for assay  C₂₅H₂₉I₂NO₃.HCl
[Same as the monograph Amiodarone Hydrochloride. When dried, it contains not less than 99.5% of amiodarone hydrochloride (C₂₅H₂₉I₂NO₃.HCl).]

Ammonia-ammonium chloride buffer solution, pH 8.0
To ammonium acetate TS add ammonia TS dropwise to adjust the pH to 8.0.

Ammonia-ammonium chloride buffer solution, pH 8.5
Dissolve 50 g of ammonium acetate in 800 mL of water and 200 mL of ethanol (95), and add ammonia solution (28) to adjust the pH to 8.5.

Ammonia-ammonium chloride buffer solution, pH 8.0
Dissolve 1.07 g of ammonium chloride in water to make 100 mL, and adjust the pH to 8.0 by adding diluted ammonia TS (1 in 30).

Ammonia-ammonium chloride buffer solution, pH 10.0
Dissolve 70 g of ammonium chloride in water, add 100 mL of ammonia solution (28), dilute with water to make 1000 mL, and add ammonia solution (28) dropwise to adjust the pH to 10.0.

Ammonia-ammonium chloride buffer solution, pH 10.7
Dissolve 67.5 g of ammonium chloride in water, add 570 mL of ammonia solution (28), and dilute with water to make 1000 mL.

Ammonia-ammonium chloride buffer solution, pH 11.0
Dissolve 53.5 g of ammonium chloride in water, add 480 mL of ammonia solution (28), and dilute with water to make 1000 mL.

Ammonia copper TS To 0.5 g of cupric carbonate monohydrate add 10 mL of water, triturate, and add 10 mL of ammonia solution (28).

Ammonia-ethanol TS To 20 mL of ammonia solution (28) add 100 mL of ethanol (99.5).

Ammonia gas NH₃ Prepare by heating ammonia solution (28).

Ammonia-saturated 1-butanol TS To 100 mL of 1-butanol add 60 mL of diluted ammonia solution (28) (1 in 100), shake vigorously for 10 minutes, and allow to stand. Use the upper layer.

Ammonia solution (28) NH₃OH [K 8085, Ammonia Water, Special class, Density: 0.90 g/mL, Content: 28 – 30%]

Ammonia TS To 400 mL of ammonia solution (28) add water to make 1000 mL (10%).

1 mol/L Ammonia TS To 65 mL of ammonia solution (28) add water to make 1000 mL.

13.5 mol/L Ammonia TS To exactly 9 mL of water add ammonia solution (28) to make exactly 50 mL.

Ammonia water See ammonia TS.

1 mol/L Ammonia water See 1 mol/L ammonia TS.

13.5 mol/L Ammonia water See 13.5 mol/L ammonia TS.

Ammonia water, strong See ammonia solution (28).

Ammonium acetate  CH₃COONH₄ [K 8359, Special class]

Ammonium acetate TS Dissolve 10 g of ammonium acetate in water to make 100 mL.

0.5 mol/L Ammonium acetate TS Dissolve 38.5 g of ammonium acetate in water to make 1000 mL.

Ammonium amidosulfate NH₄OSO₂NH₂ [K 8588, Special class]

Ammonium amidosulfate TS Dissolve 1 g of ammonium amidosulfate in water to make 40 mL.

Ammonium amminetrichloroplatinate for liquid chromatography Cl₂H₅N₂Pt To 20 g of cisplatin add 600 mL of 6 mol/L hydrochloric acid TS, and heat under a reflux con-
Ammonium chloride - NH₄Cl [K 8116, Special class]

Ammonium chloride-ammonia TS To ammonia solution (28) add an equal volume of water, and saturate this solution with ammonium chloride.

Ammonium chloride buffer solution, pH 10 Dissolve 5.4 g of ammonium chloride in water, and add 21 mL of ammonia solution (28) and water to make 100 mL.

Ammonium chloride TS Dissolve 10.5 g of ammonium chloride in water to make 100 mL (2 mol/L).

Ammonium citrate See diammmonium hydrogen citrate.

Ammonium dihydrogenphosphate - NH₄H₂PO₄ [K 9006, Special class]

0.02 mol/L Ammonium dihydrogenphosphate TS Dissolve 2.30 g of ammonium dihydrogenphosphate in water to make 1000 mL.

Ammonium formate HCOONH₄ Colorless crystals. Very soluble in water. Melting point <2.60°: 116 – 119°C

0.05 mol/L Ammonium formate buffer solution, pH 4.0 Dissolve 3.15 g of ammonium formate in 750 mL of water, adjust to pH 4.0 with formic acid, and add water to make 1000 mL.

Ammonium hydrogen carbonate - NH₄HCO₃ White or semi-transparency crystals, crystalline powder or masses, having an ammonia odor.

Ammonium iron (II) sulfate hexahydrate FeSO₄(NH₄)₂SO₄.6H₂O [K 8979, Special class]

Ammonium iron (III) citrate [Same as the monograph Ferric Ammonium Citrate in the Japanese Standards of Food Additives]

Ammonium iron (III) sulfate dodecahydrate FeNH₄(SO₄)₂.12H₂O [K 8982, Special class]

Ammonium iron (III) sulfate TS Dissolve 8 g of ammonium iron (III) sulfate dodecahydrate in water to make 100 mL.

Ammonium iron (III) sulfate, acidic Dissolve 20 g of ammonium iron (III) sulfate dodecahydrate in a suitable amount of water, add 9.4 mL of sulfuric acid, and add water to make 100 mL.

Ammonium iron (III) sulfate, dilute To 2 mL of ammonium iron (III) sulfate TS add 1 mL of 1 mol/L hydrochloric acid TS and water to make 100 mL.

Ammonium molybdate See hexaammonium heptamolybdate tetrahydrate.

Ammonium molybdate-sulfuric acid TS See hexaammonium heptamolybdate-sulfuric acid TS

Ammonium molybdate TS See hexaammonium heptamolybdate TS.

Ammonium nickel (II) sulfate See ammonium nickel (II) sulfate hexahydrate.

Ammonium nickel (II) sulfate hexahydrate

denser for 4 – 6 hours to boil while stirring. After cooling, evaporate the solvent, and dry the orange residue at room temperature under reduced pressure. To the residue so obtained add 300 mL of methanol, and heat at about 50°C to dissolve. Filter, separate insoluble yellow solids, and wash the solids with 10 mL of methanol. Combine the filtrate and the washing, heat at about 50°C, and add slowly 100 mL of ethyl acetate while stirring. Cool the mixture to room temperature avoiding exposure to light, and allow to stand at –10°C for 1 hour. Filter the mixture to take off the formed crystals, wash the crystals with 100 mL of acetone, combine the washing, heat at about 50°C, and add slowly 100 mL of ethyl acetate while stirring. Cool the mixture to room temperature under reduced pressure. It is a yellow-brown crystalline powder.

Identification - Determine the infrared absorption spectrum of the substance to be examined, previously dried at 80°C for 3 hours, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3480 cm⁻¹, 3220 cm⁻¹, 1622 cm⁻¹, 1408 cm⁻¹ and 1321 cm⁻¹.

Purity Related substances - Cisplatin Conduct this procedure using light-resistant vessels. Dissolve 10 mg in N,N-dimethylformamide to make exactly 10 mL, and use this solution as the sample solution. Separately, dissolve 10 mg of cisplatin in N,N-dimethylformamide to make exactly 50 mL. Pipet 5 mL of this solution, add N,N-dimethylformamide to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 40 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions, and determine the peak area of cisplatin by the automatic integration method: the peak area from the sample solution is not larger than that from the standard solution.

Operating conditions
Proced as directed in the operating conditions in the Assay under Cisplatin.

System suitability
System performance: When the procedure is run with 40 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of cisplatin are not less than 2500 and not more than 2.0, respectively.

System repeatability: When the test is repeated 6 times with 40 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of cisplatin is not more than 5.0%.

Ammonium aurintricarboxylate See aluminon.

Ammonium carbonate [K 8613, Special class]

Ammonium carbonate TS Dissolve 20 g of ammonium carbonate in 20 mL of ammonia TS and water to make 100 mL.
(NH₄)₂Ni(SO₄)₂·6H₂O Green crystals or crystalline powder.

**Identification**—(1) Dissolve 1 g of ammonium nickel (II) sulfate hexahydrate in 20 mL of water, and use this as the sample solution. To 5 mL of the sample solution add 1 mL of barium chloride TS: a white precipitate is produced.

(2) To 5 mL of the sample solution obtained in (1) add 5 mL of 8 mol/L sodium hydroxide TS: a green precipitate is formed, and the liquid evolves ammonia on heating.

(3) To 5 mL of the sample solution obtained in (1) add 1 mL of ammonium TS and dimethyldiethanolamine TS: a red precipitate is formed.

**Content:** not less than 99.0%. Assay—Weigh accurately about 1 g of ammonium nickel (II) sulfate hexahydrate, add 100 mL of water and 5 mL of ammonium chloride TS, then add exactly 20 mL of 0.1 mol/L disodium dihydrogen ethylenediamine tetaacetate VS, warm to 50 – 60°C, add 10 mL of diluted ammonia solution (28) (1 in 2), and titrate with 0.1 mol/L disodium dihydrogen ethylenediamine tetaacetate VS until the color of the solution is changed from green to blue-purple (indicator: 0.05 g of murexide-sodium chloride indicator).

Each mL of disodium dihydrogen ethylenediamine tetaacetate VS = 39.50 mg of (NH₄)₂Ni(SO₄)₂·6H₂O

**Ammonium nitrate** NH₄NO₃ [K 8545, Special class]

**Ammonium oxalate** See ammonium oxalate monohydrate.

**Ammonium oxalate monohydrate** (NH₄)₂C₂O₄·H₂O [K 8521, Special class]

**Ammonium oxalate TS** Dissolve 3.5 g of ammonium oxalate monohydrate in water to make 100 mL (0.25 mol/L).

**Ammonium peroxodisulfate** (NH₄)₂S₂O₈ [K 8522, Special class]

10% **Ammonium peroxodisulfate TS** Dissolve 1 g of ammonium peroxodisulfate in water to make 10 mL.

**Ammonium persulfate** See ammonium peroxodisulfate.

**Ammonium polysulfide TS** (NH₄)₂Sₓ [K 8943, Ammonium Sulfide Solution (yellow), First class]

**Ammonium sodium hydrogenphosphate tetrahydrate** NaNH₄HPO₄·4H₂O [K 9013, Special class]

**Ammonium sulfamate** See ammonium amidosulfate.

**Ammonium sulfamate TS** See ammonium amidosulfate TS.

**Ammonium sulfate** (NH₄)₂SO₄ [K 8960, Special class]

**Ammonium sulfate buffer solution** Dissolve 264 g of ammonium sulfate in 1000 mL of water, add 1000 mL of 0.5 mol/L sulfuric acid TS, shake, and filter. The pH of this solution is about 1.

**Ammonium sulfide TS** (NH₄)₂S [K 8943, Ammonium Sulfide Solution, (colorless), First class] Store in small, well-filled containers, protected from light.

**Ammonium tartrate** See L-ammonium tartrate.

**L-Ammonium tartrate** C₄H₇N₂O₆ [K 8534, (+) Ammonium tartrate, Special class]
solution, and add the mobile phase to make exactly 20 mL. Confirm that the peak area of amygdalin obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.

System performance and system repeatability: Proceed as directed in the system suitability in the Assay (3) under Keishibukuryogon Extract.

Amygdalin for component determination See amygdalin for assay.

Amygdalin for thin-layer chromatography \( \text{C}_{20}\text{H}_{27}\text{NO}_{11} \), A white, odorless powder. Soluble in water, sparingly soluble in methanol, and practically insoluble in diethyl ether, anesthetic.

Identification—Determine the absorption spectrum of a solution of amygdalin for thin-layer chromatography in methanol (1 in 1000) as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits maxima between 250 nm and 254 nm, between 255 nm and 259 nm, between 261 nm and 265 nm, and between 267 nm and 271 nm.

Purity Related substances—Dissolve 5 mg of amygdalin for thin-layer chromatography in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL of each of the sample solution and standard solution as directed in the Identification under Peach Kernel: any spot other than the principal spot at the Rf value of about 0.3 obtained from the sample solution is not more intense than the spot from the standard solution.

\( n \)-Amyl alcohol \( \text{CH}_3(\text{CH}_2)_4\text{OH} \), Clear, colorless liquid, having a characteristic odor. Sparingly soluble in water, and miscible with ethanol (95% unresolved) and with diethyl ether. Refractive index <2.45> nD 20: 1.409 – 1.411

Specific gravity <2.56> dD 20: 0.810 – 0.820

Distilling range <2.57>: 135 – 140°C, not less than 95 vol%.

\( t \)-Amyl alcohol \( \text{CH}_3(\text{CH}_2)_4\text{CH}2\text{CH}_3 \), Clear, colorless liquid, having a characteristic odor. Miscible with tert-butanol and with 2-butanol, and freely soluble in water. Specific gravity <2.56> dD 20: 0.808 – 0.815

Purity Acid and ester—To 20 mL of \( t \)-amyl alcohol add 20 mL of ethanol (95%) and 5.0 mL of 0.1 mol/L sodium hydroxide VS, and heat gently under a reflux condenser in a water bath for 10 minutes. Cool, add 2 drops of phenolphthalein TS, and titrate <2.50> with 0.1 mol/L hydrochloric acid VS. Perform a blank determination: not more than 1.25 mL of 0.1 mol/L sodium hydroxide VS is consumed.

Nonvolatile residue—Evaporate 50 mL of \( t \)-amyl alcohol, and dry at 105°C for 1 hour: the residue is not more than 1.6 mg.

Distilling range <2.57>: 100 – 103°C, not less than 95 vol%.

\( t \)-Amyl alcohol See \( t \)-amyl alcohol.

Amyl alcohol, iso See 3-methyl-1-butanol.

Anesthetic ether See ether, anesthetic.

Anhydrous caffeine See caffeine, anhydrous.

Anhydrous cupric sulfate See copper (II) sulfate (anhydrous).

Anhydrous dibasic sodium phosphate See disodium hydrogen phosphate.

Anhydrous dibasic sodium phosphate for pH determination See disodium hydrogen phosphate for pH determination.

Anhydrous hydrazine for amino acid analysis Prepared for amino acid analysis.

Anhydrous lactose \( \text{C}_{12}\text{H}_{22}\text{O}_{11} \) [Same as the monograph Anhydrous Lactose]

Anhydrous potassium carbonate See potassium carbonate.

Anhydrous sodium acetate See sodium acetate, anhydrous.

Anhydrous sodium carbonate See sodium carbonate, anhydrous.

Anhydrous sodium sulfate See sodium sulfate, anhydrous.

Anhydrous sodium sulfite See sodium sulfite, anhydrous.

Aniline \( \text{C}_{6}\text{H}_5\text{NH}_2 \) [K 8042, Special class]

Animal tissue peptone See peptone, animal tissue.

p-Anisaldehyde See 4-methoxybenzaldehyde.

p-Anisaldehyde-acetic acid TS See 4-methoxybenzaldehyde-acetic acid TS.

p-Anisaldehyde-sulfuric acid TS See 4-methoxybenzaldehyde-sulfuric acid TS.

Anisole \( \text{C}_7\text{H}_8\text{O} \), A colorless liquid. Boiling point: about 155°C. Specific gravity <2.56> dD 20: 0.995 – 1.001.

14-Anisoylacetone hydrochloride for assay \( \text{C}_3\text{H}_5\text{NO}_{11}.\text{HCl},\text{H}_2\text{O} \), White crystalline powder or powder. Freely soluble in methanol, sparingly soluble in water and in ethanol (99.5%). Melting point: about 210°C (with decomposition).

Absorbance <2.24> E1% (258 nm): 276 – 294 (5 mg calculated on the anhydrous basis, methanol, 200 mL).

Purity (1) Related substances—To 1.0 mg of 14-anisoylacetone hydrochloride for assay add exactly 1 mL of ethanol (99.5%). Perform the test with 5 μL of this solution as directed in the Identification under Processed Aconite Root: no spot other than the principle spot at around Rf value of 0.5 appears.

(2) Related substances—Dissolve 5.0 mg of 14-anisoylacetone hydrochloride for assay in 5 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of this solution, add the mobile phase to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the total area of the peaks other than the peak of 14-anisoylacetone obtained from the sample solution is not larger than the peak area of 14-anisoylacetone from the standard solution.

Operating conditions
Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay (3) under Goshajinkigan Extract.
Detector: An ultraviolet absorption photometer (wavelength: 245 nm).
Time span of measurement: About 4 times as long as the retention time of 14-anisoylaconine.

System suitability
Test for required detectability: Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 20 mL. Confirm that the peak area of 14-anisoylaconine obtained from 20 μL of this solution is equivalent to 3.5 to 6.5% of that of 14-anisoylaconine from 20 μL of the standard solution.

System performance: When the procedure is run with 20 μL of aconitum monoester alkaloids standard TS for assay under the above operating conditions, benzoylmesaconine, benzoylpyaconine and 14-anisoylaconine are eluted in this order with the resolution between these peaks being not less than 4.

System repeatability: When the test is repeated 6 times with 20 μL of aconitum monoester alkaloids standard TS for assay under the above operating conditions, the relative standard deviations of the peak areas of benzoylmesaconine, benzoylpyaconine and 14-anisoylaconine are not more than 1.5%, respectively.

14-Anisoylaconine hydrochloride for component determination
See 14-anisoylaconine hydrochloride for assay.

Anode solution A for water determination
Dissolve 100 g of diethanolamine in 900 mL of a mixture of methanol for water determination and chloroform for water determination (1:1), pass dried sulfur dioxide gas through this solution while cooling until the mass increase of the solution reaches 64 g. Then add 20 g of iodine, and add water until the color of the solution changes from brown to yellow. To 600 mL of this solution add 400 mL of chloroform for water determination.

Anthrone
C14H10O
Light yellow crystals or crystalline powder.
Melting point
≤2.60°: 154 – 160°C.
Preserve in a light-resistant tight container.

Anthrone TS
Dissolve 35 mg of anthrone in 100 mL of sulfuric acid.

Anti-A type antibody for blood typing
Conforms to the requirements of antibody for blood typing.

Anti-B type antibody for blood typing
Conforms to the requirements of antibody for blood typing.

Antibody fragment (Fab')
Purify E. coli protein antibody by affinity chromatography using Staphylococcus aureus protein A as a ligand, and fractionate IgG. Digest this fraction using pepsin, remove the pepsin and Fc fragment by gel filtration chromatography, and obtain F(ab')2 fragment after removing undigested IgG by affinity chromatography with protein A as ligand. Reduce this with 2-mercaptoethanol.

Anti-bradykinin antibody
A colorless to light brown, clear solution prepared by dissolving rabbit origin anti-bradykinin antibody in 0.04 mol/L phosphate buffer solution, pH 7.0 containing 1 mg/mL of bovine serum albumin.

Performance test—To a suitable amount of anti-bradykinin antibody to be tested add 0.04 mol/L phosphate buffer solution, pH 7.0 containing 1 mg/mL bovine serum albumin to make a 1 vol% solution. Perform the test with 0.1 mL of this solution as directed in the Purity (2) under Kallidinogenase, and determine the absorbances at 490 – 492 nm, A1 and A2, of the standard solution (1) and the standard solution (7): the value, A2 – A1, is not less than 1.

Anti-bradykinin antibody TS
To 0.15 mL of anti-bradykinin antibody, 15 mg of bovine serum albumin, 2.97 mg of sodium dihydrogen phosphate dihydrate, 13.5 mg of disodium hydrogen phosphate dodecahydrate and 13.5 mg of sodium chloride add water to make 15 mL, and lyophilize. Dissolve this in 15 mL of water. Prepare before use.

Anti-E. coli protein antibody stock solution
Taking E. coli protein stock solution as the immunogen, mix with Freund’s complete adjuvant, and immunize rabbits by subcutaneous injection at 3 week intervals to obtain antiserum. Treat the antiserum obtained by ammonium sulfate precipitation.

Protein concentration: Dilute anti-E. coli protein antibody stock solution with 0.05 mol/L tris hydrochloride buffer solution (pH 7.5), measure the absorbance at 280 nm using 0.05 mol/L tris hydrochloride buffer solution (pH 7.5) as a control as direct under Ultraviolet-visible Spectrophotometry <2.24>, and determine the protein concentration (absorbance 1.0 = 0.676 mg/mL).

Antimony (III) chloride
SbCl3 [K 8400, Special class]
Antimony (III) chloride TS
Wash chloroform with an equal volume of water twice or three times, add freshly ignited and cooled potassium carbonate, and allow to stand overnight in a well-closed container protected from light. Separate the chloroform layer, and distil it, preferably with protection from light. With this chloroform, wash the surface of antimony (III) chloride until the rinsing solution becomes clear, add the chloroform to this antimony (III) chloride to make a saturated solution, and place in light-resistant, glass-stoppered bottles. Prepare before use.

Antimony trichlorid
See antimony (III) chloride.

Antimony trichlorid TS
See antimony (III) chloride TS.

Antipyrine
C11H12N2O [Same as the namesake monograph]
Anti-rabbit antibody-coated wells
Wells of a polystyrene microplate coated with goat origin anti-rabbit IgG antibody.

Anti-thrombin III
A white powder.
Water <2.48>: not more than 5%.
Content: not less than 80% and not more than 130% of the labeled amount.

Anti-thrombin III TS
Dissolve 10 unit of anti-thrombin III in 10 mL of water.

Anti-ulinastatin rabbit serum
To a suitable amount of Ulinastatin having the specific activity of more than 3000 Units per mg protein add isotonic sodium chloride solution so that each mL of the solution contains about 1 mg of protein. To 1 mL of this solution add 1 mL of Freund’s complete adjuvant, and emulsify completely. Intracutaneously, inject the emulsion so obtained into a rabbit weighing about
2 kg. Repeat the injection at least 4 times at one-week intervals, and draw the blood of the animal from the carotid artery after the antibody titer reaches 16 times or more. Separate the serum after the blood has coagulated. Preserve at below 20°C.

**Anti-urokinase serum** Take Urokinase containing not less than 140,000 Unit per mg of protein, dissolve in isotonic sodium chloride solution to make a solution containing 1 mg of protein per mL, and emulsify with an equal volume of Freund’s complete adjuvant. Inject intracutaneously three 2-mL portions of the emulsion to a healthy rabbit weighed between 2.5 kg and 3.0 kg in a week interval. Collect the blood from the rabbit at 7 to 10 days after the last injection, and prepare the anti-serum.

**Performance test**—Dissolve 1.0 g of agar in 100 mL of boric acid-sodium hydroxide buffer solution, pH 8.4, by warming, and pour the solution into a Petri dish to make a depth of about 2 mm. After cooling, bore three of a pair-well 2.5 mm in diameter with a space of 6 mm each other. In one of the wells of each pair-well, place 10 μL of anti-urokinase serum, and in each another well, place 10 μL of a solution of Urokinase containing 30,000 Units per mL in isotonic sodium chloride solution, 10 μL of human serum and 10 μL of human urine, respectively, and allow to stand overnight: a precipitin line appears between anti-urokinase serum and urokinase, and not appears between anti-urokinase serum and human serum or human urine.

α-Apoxytetracycline C_{22}H_{22}N_{2}O_{8} Yellow-brown to green powder.

Melting point <2.60°: 200 – 205°C

β-Apoxytetracycline C_{22}H_{22}N_{2}O_{8} Yellow-brown to brown powder.

**Purity** Related substances—Dissolve 8 mg of β-apoxygenyctetracycline in 5 mL of 0.01 mol/L sodium hydroxide TS, add 0.01 mol/L hydrochloric acid TS to make 100 mL, and use this solution as the sample solution. Proceed the test with 20 μL of the sample solution as directed in the Purity (2) under Oxytetracycline Hydrochloride, determine each peak area by the automatic integration method, and calculate the amounts of them by the area percentage method: the total amount of the peaks other than β-apoxygenyctetracycline is not more than 10%.

**Aprimidine hydrochloride for assay** C_{22}H_{30}N_{2}HCl

[Same as the monograph Aprimidine Hydrochloride. When dried, it contains not less than 99.5% of aprimidine hydrochloride (C_{22}H_{30}N_{2}HCl).]

Aprotinin A clear and colorless liquid containing aprotinin extracted from the lung or parotid gland of a healthy cat.

The pH is between 5.0 and 7.0.

**Content**: not less than 15,000 KIE Units and not more than 25,000 KIE Units of aprotinin per mL. Assay—(i) Trypsin solution: Weigh an amount of crystalline trypsin equivalent to about 250 FIP Units of trypsin according to the labeled FIP Units, and dissolve in 0.001 mol/L hydrochloric acid TS to make exactly 10 mL. Prepare before use, and preserve in ice. (ii) Sample solution: Dilute a suitable quantity of aprotinin with sodium tetraborate-calcium chloride buffer solution, pH 8.0 so that each mL of the solution contains 800 KIE Units of aprotinin, and use this solution as the sample solution. (iii) Apparatus: Use a glass bottle as a reaction reservoir, 20 mm in inside diameter and 50 mm in height, equipped with a rubber stopper for attachment to a glass/silver-silver chloride electrode, a nitrogen-induction tube and an exhaust port. Fix the reaction reservoir in a thermostat, and keep the temperature of the bath at 25 ± 0.1°C by means of a precise thermoregulator. (iv) Procedure: To 5.0 mL of N-α-benzoyl-L-arginine ethyl ester TS add 45.0 mL of sodium tetraborate-calcium chloride buffer solution, pH 8.0, and use this solution as the substrate solution. Pipet 1 mL of the trypsin solution, add sodium tetraborate-calcium chloride buffer solution, pH 8.0 to make exactly 10 mL, and use this solution as the test solution I. Transfer 10.0 mL of the substrate solution to the reaction reservoir, adjust the pH of the solution to 8.00 by adding dropwise 0.1 mol/L sodium hydroxide VS while stirring and passing a current of nitrogen, add exactly 1 mL of the test solution I previously allowed to stand at 25 ± 0.1°C for 10 minutes, then immediately add dropwise 0.1 mol/L sodium hydroxide VS by a 50-μL micropipet (minimum graduation of 1 μL), while stirring, to keep the reaction solution at pH 8.00, and read the amount of 0.1 mol/L sodium hydroxide VS consumed and the reaction time when the pH reached 8.00. Continue this procedure up to 6 minutes. Separately, pipet 2 mL of the trypsin solution and 1 mL of the sample solution, add sodium tetraborate-calcium chloride buffer solution, pH 8.0 to make exactly 10 mL, and use this solution as the test solution II. Transfer 10.0 mL of the substrate solution to the reaction reservoir, adjust the pH of the solution to 8.00, while stirring and passing a current of nitrogen, add exactly 1 mL of the test solution II, previously allowed to stand at 25 ± 0.1°C for 10 minutes, and proceed in the same manner. Separately, transfer 10.0 mL of the substrate solution to the reaction reservoir, adjust the pH of the solution to 8.00, while stirring and passing a current of nitrogen, add 1 mL of sodium tetraborate-calcium chloride buffer solution, pH 8.0, previously allowed to stand at 25 ± 0.1°C for 10 minutes, and perform a blank determination in the same manner. (v) Calculation: Plot the amount of consumption (f) of 0.1 mol/L sodium hydroxide VS against the reaction time (minutes), select linear reaction times, t₁ and t₂, designate the corresponding consumption amount of 0.1 mol/L sodium hydroxide VS as v₁ and v₂, respectively, and designate μmol of sodium hydroxide consumed per minute as D.

\[
D (\mu\text{mol NaOH/min}) = \frac{v_2 - v_1}{t_2 - t_1} \times \frac{1}{10} \times f
\]

f: Factor of 0.1 mol/L sodium hydroxide VS

KIE Units per mL of aprotinin to be tested

\[
= \frac{2(D_A - D_S) - (D_B - D_S)}{L} \times n \times 32.5
\]

L: Amount (mL) of the sample solution added to the test solution II
n: Dilution coefficient of aprotinin to be tested
Dₐ: μmol of sodium hydroxide consumed in 1 minute when the test solution I is used
Dₐ: μmol of sodium hydroxide consumed in 1 minute when the test solution II is used
Dₐ: μmol of sodium hydroxide consumed in 1 minute when the solution for blank determination is used
32.5: Equivalent coefficient for calculation of KIE Units from FIP Units
One KIE Unit means an amount of aprotinin making a reduction of 50% off the potency of 2 Units of kallidinogenase at pH 8.0 and room temperature for 2 hours.

Storage—Preserve in a light-resistant, hermetic container and in a cold place.

Aprotinin TS Measure an appropriate amount of aprotinin, and dissolve in 0.05 mol/L phosphate buffer solution, pH 7.0 to prepare a solution containing 50 KIE Units per mL.

Aquæ regiæ Add 1 volume of nitric acid to 3 volumes of hydrochloric acid. Prepare before use.

L-Arabinose C_{6}H_{17}O_{7} A white crystalline powder. Melting point <2.600: 155 - 160°C.

Optical rotation <2.490 [α]_{D}^{20}: +103.0 - +105.5° Weigh accurately about 5 g of L-arabinose, previously dried at 105°C for 2 hours, dissolve in 30 mL of water, add 0.4 mL of ammonia TS, and add water to make exactly 50 mL. Allow to stand for 1 hour, and determine using a 100-mm cell.

Arbutin for assay Use arbutin for thin-layer chromatography meeting the following additional specifications.

Absorbance <2.240 E_{1%}^{10} (280 nm): 70 - 76 [4 mg, previously dried in a desiccator (in vacuum, silica gel), 12 hours, water, 100 mL].

Purity Related substances—Dissolve 40 mg of arbutin for assay in 100 mL of water, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add water to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 10 μL of the sample solution and standard solution (1) as directed in the operating conditions and measure each peak area of the both solutions by the automatic integration method: the total area of the peaks other than that of arbutin from the sample solution is not larger than the peak area of arbutin from the standard solution (1).

Operating conditions Proceed the operating conditions in the Assay under Bearberry Leaf except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add water to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of arbutin obtained from 10 μL of the standard solution (2) can be measured by the automatic integration method and the peak height of arbutin obtained from 10 μL of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About 3 times as long as the retention time of arbutin beginning after the solvent peak.

Arbutin for component determination See arbutin for assay.

Arbutin for thin-layer chromatography C_{13}H_{19}O_{7}·nH_{2}O Colorless to white crystals or crystalline powder, and odorless. Freely soluble in water, soluble in methanol, sparingly soluble in ethanol (95), and practically insoluble in ethyl acetate and in chloroform.

Melting point <2.600: 199 - 201°C

Purity Related substances—Dissolve 1.0 mg of arbutin for thin-layer chromatography in exactly 1 mL of a mixture of ethanol (95) and water (7:3). Perform the test with 20 μL of this solution as directed in the Identification (2) under Bearberry Leaf: any spot other than the main spot at the Rf value of about 0.4 does not appear.

Acorus japonicus hydrobromide for thin-layer chromatography C_{12}H_{16}O_{7}·HBr White crystals. Freely soluble in water, soluble in methanol, and practically insoluble in diethyl ether.

Melting point <2.600: 169 - 171°C

Purity Related substances—Dissolve 5 mg of aconitum hydrobromide for thin-layer chromatography in exactly 1 mL of methanol. Perform the test with 10 μL of this solution as directed in the Identification under Area: any spot other than the principal spot at the Rf value of about 0.6 does not appear.

L-Arginine C_{6}H_{14}N_{2}O_{2} White, crystals or crystalline powder. It has a characteristic odor.

Optical rotation <2.490 [α]_{D}^{20}: +26.9 - +27.9° (After drying, 4 g, 6 mol/L hydrochloric acid TS, 50 mL, 200 mm). Loss on drying <2.410: not more than 0.50% (1 g, 105°C, 3 hours).

Content: not less than 98.0% and not more than 102.0%. Assay—Weigh accurately about 0.15 g of L-arginine, previously dried, dissolve in 3 mL of formic acid, add 50 mL of acetic acid (100), and titrate <2.500 with 0.1 mol/L perchloric acid VS until the color of the solution changes to green through yellow (indicator: 10 drops of p-naphtholbenzein TS). Perform a blank determination in the same manner and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 8.710 mg of C_{6}H_{14}N_{2}O_{2}

L-Arginine hydrochloride C_{6}H_{14}N_{2}O_{2}·HCl [Same as the namesake monograph]

Aristolochic acid I for crude drugs purity test

C_{7}H_{12}O_{7} Yellow crystalline powder. Melting point: about 280°C (with decomposition).

Absorbance <2.240 E_{1%}^{10} (318 nm): 384 - 424 (1 mg, methanol, 100 mL).

Purity Related substances—Dissolve 1.0 mg of aristolochic acid I for crude drugs purity test in 100 mL of diluted methanol (3 in 4), and use this solution as the sample solution. Pipet 1 mL of this solution, add diluted methanol (3 in 4) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.010 according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than aristolochic acid I obtained from the sample solution is not larger than the peak area of aristolochic acid I from the standard solution.

Operating conditions

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Purity (4) under Asiasarum Root.

Time span of measurement: About 3 times as long as the retention time of aristolochic acid I beginning after the solvent peak.

System suitability

Proceed as directed in the system suitability in the Purity.
L-Ascorbic acid \( \text{C}_{6}\text{H}_8\text{O}_6 \) [K 9502, L(+)-Ascorbic Acid, Special class]

Ascorbic acid for iron limit test
See L-ascorbic acid.

0.012 g/dL L-Ascorbic acid-hydrochloric acid TS
Dissolve 15 mg of L-ascorbic acid in 25 mL of methanol, add carefully 100 mL of hydrochloric acid, and mix. Prepare before use.

0.02 g/dL L-Ascorbic acid-hydrochloric acid TS
Dissolve 25 mg of L-ascorbic acid in 25 mL of methanol, add carefully 100 mL of hydrochloric acid, and mix. Prepare before use.

0.05 g/dL L-Ascorbic acid-hydrochloric acid TS
Dissolve 0.05 g of L-ascorbic acid in 30 mL of methanol, add carefully hydrochloric acid to make 100 mL. Prepare before use.

DL-Aspartic acid \( \text{C}_4\text{H}_7\text{NO}_4 \)
A white crystalline powder that is sparingly soluble in water. Melting point: 270 to 271°C.

L-Aspartic acid \( \text{C}_4\text{H}_7\text{NO}_4 \) [K 9045, Special class]

Aspartic acid See L-aspartic acid.

Aspirin \( \text{C}_9\text{H}_8\text{O}_4 \) [Same as the namesake monograph]

Aspirin See L-aspirin.

Atropine sulfate \( \text{C}_{17}\text{H}_{23}\text{NO}_3 \cdot \text{H}_2\text{SO}_4 \).
See atropine sulfate hydrate.

Atropine sulfate for assay See atropine sulfate hydrate for assay.

Atropine sulfate for thin-layer chromatography
See atropine sulfate hydrate.

Atropine sulfate hydrate \( \text{C}_{17}\text{H}_{23}\text{NO}_3 \cdot \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O} \) [Same as the namesake monograph]

Atropine sulfate hydrate for assay \( \text{C}_{17}\text{H}_{23}\text{NO}_3 \cdot \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O} \) [Same as the monograph Atropine Sulfate Hydrate.
When dried, it contains not less than 99.0% of atropine sulfate \([\text{C}_{17}\text{H}_{23}\text{NO}_3 \cdot \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O} ] \).]
A tropine sulfate hydrate for thin-layer chromatography
(C\textsubscript{17}H\textsubscript{22}NO\textsubscript{3})\textsubscript{2}.H\textsubscript{2}SO\textsubscript{4}.H\textsubscript{2}O Use atropine sulfate hydrate for assay meeting the following additional specifications. Weigh accurately about 50 mg of atropine sulfate hydrate for assay, dissolve in ethanol (95) to make 10 mL, and use this solution as the sample solution. Perform the test with the sample solution as directed under Thin-layer Chromatography \( \mu \text{L} \). Spot 50 \( \mu \text{L} \) of the solution on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of chloroform and diethylamine (9:1) to a distance of about 10 cm, air-dry the plate, and spray evenly chloroplatinic acid-potassium iodide TS on the plate: any spot other than the spot at the \( Rf \) value of about 0.4 does not appear.

**A-type erythrocyte suspension** Prepare a suspension containing 1 vol\% of erythrocyte separated from human A-type blood in isotonic sodium chloride solution.

Azelaistine hydrochloride for assay C\textsubscript{21}H\textsubscript{18}O\textsubscript{11}.H\textsubscript{2}O Light yellow odorless powder. Slightly soluble in water, slightly soluble in ethanol (95), and practically insoluble in methanol, and practically insoluble in water and in diethyl ether. Melting point: about 206°C (with decomposition).

**Purity** Related substance—Dissolve 1.0 mg of azelaistine hydrate for thin-layer chromatography in exactly 1 mL of methanol. Perform the test with 10 \( \mu \text{L} \) of this solution as directed in the Identification (2) under Scutellaria Root: any spot other than the principal spot at the \( Rf \) value of about 0.4 does not appear.

**Bakumondo** [Same as the namesake monograph]

Balsam Canada balsam for microscopy. Before use, dilute to a suitable concentration with xylene.

**Bamethan sulfate** (C\textsubscript{17}H\textsubscript{23}NO\textsubscript{3})\textsubscript{2}.H\textsubscript{2}SO\textsubscript{4} [Same as the namesake monograph]

**Barbaloin for assay** C\textsubscript{21}H\textsubscript{22}O\textsubscript{9} Use barbaloin for thin-layer chromatography in exactly 1 mL of methanol.

**Barbaloin for thin-layer chromatography** C\textsubscript{21}H\textsubscript{22}O\textsubscript{9}.H\textsubscript{2}O Light yellow odorless powder. Freely soluble in methanol, practically insoluble in water and in diethyl ether.

**Barbital** C\textsubscript{8}H\textsubscript{12}N\textsubscript{2}O\textsubscript{3} [Same as the namesake monograph]

**Barbital buffer solution** Dissolve 15 g of barbital sodium in 700 mL of water, adjust the pH to 7.6 with dilute hydrochloric acid, and filter.

**Barbital sodium** C\textsubscript{8}H\textsubscript{11}N\textsubscript{2}NaO\textsubscript{3}. White, odorless crystals of crystalline powder, having a bitter taste. Freely soluble in water, slightly soluble in ethanol (95), and practically insoluble in diethyl ether.

**pH** \( \text{H} \rightarrow \text{L} \). The pH of a solution of barbital sodium (1 in 200) is between 9.9 and 10.3.

**Loss on drying** \( \text{L} \). Assay—Weigh accurately about 0.5 g of barbital sodium, previously dried, transfer to a separator, dissolve in 20 mL of water, add 5 mL of ethanol (95) and 10 mL of dilute hydrochloric acid, and extract with 50 mL of chloroform. Then extract with three 25-mL portions of chloroform, combine the total extract, wash with two 5-mL portions of water, and extract the washings with two 10-mL portions of chloroform. Combine the chloroform extracts, and filter into a conical flask. Wash the filter paper with three 5-mL portions of chloroform, combine the filtrate and the washings, add 10 mL of ethanol (95), and titrate with 0.1 mol/L potassium hydroxide-ethanol VS until the color of the solution changes from yellow to purple through light purple (indicator: 2 mL of alizarin yellow GG-thymolphthalein TS). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L potassium hydroxide-ethanol VS = 20.62 mg of C\textsubscript{8}H\textsubscript{11}N\textsubscript{2}NaO\textsubscript{3}.

**Barium chloride** See barium chloride dihydrate.

**Barium chloride dihydrate** BaCl\textsubscript{2}.2H\textsubscript{2}O [K 8155, Special class]

**Barium chloride TS** Dissolve 12 g of barium chloride dihydrate in water to make 100 mL (0.5 mol/L).

**Barium hydroxide** See barium hydroxide octahydrate.
Barium hydroxide octahydrate \( \text{Ba(OH)}_2 \cdot 8\text{H}_2\text{O} \) [K 8577, Special class] Store in tightly stoppered containers.

Barium hydroxide TS Saturate barium hydroxide octahydrate in freshly boiled and cooled water (0.25 mol/L). Prepare before use.

Barium nitrate \( \text{Ba(NO_3)}_2 \) [K 8565, Special class]

Barium nitrate TS Dissolve 6.5 g of barium nitrate in water to make 100 mL (0.25 mol/L).

Barium oxide \( \text{BaO} \) A white to yellowish or grayish white, powder.

Identification (1) Dissolve 0.5 g in 15 mL of water and 5 mL of hydrochloric acid, and add 10 mL of dilute sulfuric acid: white precipitates appear.

(2) Perform the test as directed under Flame Coloration Test (1) \(<1.04>\); a green color appears.

Barium perchlorate \( \text{Ba(ClO}_3)_2 \) [K 9551, Special class]

Becamycin sulfate \( \text{C}_{18}\text{H}_{37}\text{N}_{3}\text{O}_{6}\cdot\text{xH}_2\text{SO}_4 \) [Same as the namesake monograph]

Beclometasone dipropionate \( \text{C}_{28}\text{H}_{31}\text{N}_{3}\text{O}_6\cdot\text{HCl} \) [Same as the namesake monograph]

Benidipine hydrochloride \( \text{C}_{28}\text{H}_{31}\text{N}_{3}\text{O}_6\cdot\text{HCl} \) [Same as the namesake monograph]

Benidipine hydrochloride for assay \( \text{C}_{28}\text{H}_{31}\text{N}_{3}\text{O}_6\cdot\text{HCl} \) [Same as the monograph Benidipine Hydrochloride. When dried, it contains not less than 99.5% of benidipine hydrochloride (\( \text{C}_{28}\text{H}_{31}\text{N}_{3}\text{O}_6\cdot\text{HCl} \)).

Benzaldehyde \( \text{C}_6\text{H}_5\text{CHO} \) [K 8857, First class]

Benzalkonium chloride [Same as the namesake monograph]

Benzaldehyde \( \text{C}_6\text{H}_5\text{CHO} \) [K 8857, First class]

Benzalkonium chloride [Same as the namesake monograph]

Benzaldehyde \( \text{C}_6\text{H}_5\text{CHO} \) [K 8857, First class]

Benzaldehyde \( \text{C}_6\text{H}_5\text{CHO} \) [K 8857, First class]

Benzathion chloride for assay \( \text{C}_6\text{H}_6\text{ClN}_2\text{O}_2 \) [Same as the monograph Benzathion Chloride. When dried, it contains not less than 99.0% of benzathion chloride (\( \text{C}_6\text{H}_6\text{ClN}_2\text{O}_2 \)).

Benzoic acid \( \text{C}_6\text{H}_5\text{COOH} \) [K 8073, Special class]

Benzoin \( \text{C}_6\text{H}_5\text{CH(OH)}\text{COC}_6\text{H}_5 \) White to pale yellow, crystals or powder.

Melting point \(<2.60>\): 132 – 137°C

Benzenophene \( \text{C}_6\text{H}_5\text{COC}_6\text{H}_5 \) Colorless crystals, having a characteristic odor.

Melting point \(<2.60>\): 48 – 50°C

Benz[\(a\)]anthracene \( \text{C}_{20}\text{H}_{12} \) Light yellow to green-yellow crystalline powder or powder. Practically insoluble in water, in methanol and in ethanol (99.5). Melting point: 176 – 181°C.

Identification—Perform the test with benz[\(a\)]anthracene as directed in the Purity: the mass spectrum of the main peak shows a molecular ion peak \((m/z\ 252)\) and a fragment ion peak \((m/z\ 125)\).

Purity Related substances—Dissolve 3.0 mg of benz[\(a\)]anthracene in methanol to make 100 mL, and use this solution as the sample solution. Perform the test with 1 \(\mu\)L of this solution as directed under Gas Chromatography \(<2.02>\) according to the following conditions, and determine each peak area by the automatic integration method. Calculate the amounts of these peaks by the area percentage method: the total amount of the peaks other than benz[\(a\)]anthracene is not more than 3.0%.

Operating conditions

Detector: A mass spectrophotometer (EI).

Mass scan range: 15.00 – 300.00.

Time of measurement: 12 – 30 minutes.

Column: A fused silica column 0.25 mm in inside diameter and 30 m in length, coated inside with 5% diphenyl-95% dimethylpolysiloxane for gas chromatography in thickness of 0.25 – 0.5 \(\mu\)m.

Column temperature: Inject at a constant temperature of about 45°C, raise the temperature to 240°C at a rate of 40°C per minute, maintain at 240°C for 5 minutes, raise to 300°C at a rate of 4°C per minute, raise to 320°C at a rate of 10°C per minute, and maintain at 320°C for 3 minutes.
Injection port temperature: A constant temperature of about 250°C.

Interface temperature: A constant temperature of about 300°C.

Carrier gas: Helium.

Flow rate: Adjust the flow rate so that the retention time of benzoprene is about 22 minutes.

Split ratio: Splitless.

System suitability
Test for required detectability: Pipet 1 mL of the sample solution, add methanol to make exactly 10 mL. Confirm that the peak area of benzo[pyrene obtained from 1 µL of this solution is equivalent to 5 to 15% of that of benzoprene from 1 µL of the sample solution.

p-Benzooquinone \( \text{C}_4\text{H}_6\text{O}_2 \) Yellow to yellow-brown, crystals or crystalline powder, having a pungent odor. Soluble in ethanol (95) and in diethyl ether, slightly soluble in water. It is gradually changed to a blackish brown color by light.

Melting point \(< 220^\circ\text{C} \): 111 - 116°C

Content: not less than 98.0%. Assay—Weigh accurately about 0.1 g of p-benzoquinone, place in an iodine bottle, add exactly 25 mL of water and 25 mL of diluted sulfuric acid (1 in 5), dissolve 3 g of potassium iodide by shaking, and titrate \( \text{C}_4\text{H}_6\text{O}_2 \) with 0.1 mol/L sodium thiosulfate VS (indicator: 3 mL of starch TS). Perform a blank determination.

Each mL of 0.1 mol/L sodium thiosulfate VS = 5.405 mg of \( \text{C}_4\text{H}_6\text{O}_2 \).

p-Benzooquinone TS Dissolve 1 g of p-benzoquinone in 5 mL of acetic acid (100), and add ethanol (95) to make 100 mL.

**N-α-Benzoyl-L-arginine ethyl ester hydrochloride** \( \text{C}_{21}\text{H}_{22}\text{N}_{6}\text{O}_4\cdot\text{HCl} \) White crystals or crystalline powder. Freely soluble in water and in ethanol (95), and slightly soluble in diethyl ether.

Melting point \(< 220^\circ\text{C} \): 129 - 133°C

Optical rotation \( < 249^\circ \) \([\alpha]_D^- \): -15.5 - -17.0° (2.5 g, water, 50 mL, 100 mm).

Purity (1) Clarity and color of solution—Dissolve 0.1 g of \( \text{N-α-benzoyl-L-arginine ethyl ester hydrochloride} \) in 20 mL of water: the solution is clear and colorless.

(2) Related substances—Weigh 0.10 g of \( \text{N-α-benzoyl-L-arginine ethyl ester hydrochloride} \), dissolve in 6 mL of water, add 4 mL of hydrochloric acid, heat in a boiling water bath for 5 minutes to decompose, and use this solution as the sample solution. Perform the test with the sample solution as directed under Paper Chromatography. Spot 5 µL of the sample solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water and acetic acid (100) (4:1:1) to a distance of about 10 cm, and air-dry the plate. Exposure the plate to a vapor of iodine: only one spot appears.

**N-α-Benzoyl-L-arginine-4-nitroanilide hydrochloride** \( \text{C}_{31}\text{H}_{43}\text{NO}_9\cdot\text{HCl} \) Light yellow crystalline powder.

**Liquid chromatography**—Dissolve 0.1 g of \( \text{N-α-benzoyl-L-arginine-4-nitroanilide hydrochloride} \) in 10 mL of \( \text{N,N-dimethylformamide} \), and use this solution as the sample solution.

Perform the test with this solution as directed under Liquid Chromatography \( < 2.0^\circ \). Spot 10 µL of the sample solution on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of 1-butanol, water and acetic acid (100) (4:1:1) to a distance of about 10 cm, and air-dry the plate. Exposure the plate to a vapor of iodine: only one spot appears.

**N-α-Benzoyl-L-arginine-4-nitroanilide TS** Dissolve 0.1 g of \( \text{N-α-benzoyl-L-arginine-4-nitroanilide hydrochloride} \) in water to make 100 mL.

**Benzoyl chloride** \( \text{C}_8\text{H}_7\text{COCl} \) A clear and colorless fuming liquid. Specific gravity: about 1.2 g/mL.

**Identification**—Determine the infrared absorption spectrum as directed in the liquid film method as directed under Infrared Spectrophotometry \( < 2.25^\circ \): it exhibits absorption at the wave numbers of about 1775 cm\(^{-1}\), 1596 cm\(^{-1}\), 1450 cm\(^{-1}\), 1307 cm\(^{-1}\), 1206 cm\(^{-1}\), 873 cm\(^{-1}\), 776 cm\(^{-1}\) and 671 cm\(^{-1}\).

**Benzoylhyponcacin hydrochloride for assay** \( \text{C}_{19}\text{H}_{22}\text{N}_{6}\text{O}_4\cdot\text{HCl} \) White crystals or crystalline powder. Freely soluble in methanol, soluble in water, and sparingly soluble in ethanol (99.5). Melting point: about 230°C (with decomposition).

Absorbance \( < 2.24^\circ \) \( E_1^1\text{cm} \): 225 - 240 (5 mg calculated on the anhydrous basis, methanol, 200 mL).

Purity (1) Related substances—To 1.0 mg of benzoylhyponcacin hydrochloride for assay add exactly 1 mL of ethanol (99.5). Perform the test with 5 µL of this solution as directed in the Identification under Processed Aconite Root: no spot other than the principal spot at around RF value of 0.5 appears.

(2) Related substance—Dissolve 5.0 mg of benzoylhyponcacin hydrochloride for assay in 5 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of this solution, add the mobile phase to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 20 µL of the sample solution and standard solution as directed under Liquid Chromatography \( < 2.0^\circ \) according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the total area of the peaks other than the peak of benzoylhyponcacin obtained from the sample solution is not larger than the peak area of benzoylhyponcacin from the standard solution.

Operating conditions
Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay (3) under Goshajinkigan Extract.
Detector: An ultraviolet absorption photometer (wavelength: 245 nm).

Time span of measurement: About 5 times as long as the retention time of benzoylhyacoline.

System suitability
Test for required detectability: Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 20 mL. Confirm that the peak area of benzoylhyacoline obtained from 20 μL of this solution is equivalent to 3.5 to 6.5% of that of benzoylmesaconine from 20 μL of the standard solution.

System performance: When the procedure is run with 20 μL of aconitum monoester alkaloids standard TS for assay under the above operating conditions, benzoylmesaconine, benzoylhyacoline and 14-anisoylaconine are eluted in this order with the resolution between these peaks being not less than 4, respectively.

System repeatability: When the test is repeated 6 times with 20 μL of aconitum monoester alkaloids standard TS for assay under the above operating conditions, the relative standard deviations of the peak areas of benzoylmesaconine, benzoylhyacoline and 14-anisoylaconine are not more than 1.5%, respectively.

**Benzoylmesaconine hydrochloride for component determination** See benzoylmesaconine hydrochloride for assay.

Absorbance ≤2.24 E₁%₁₀₀ (316 nm): 166 – 184 (10 mg, water, 300 mL).

**Benzoylmesaconine hydrochloride for assay** Benzoylmesaconine hydrochloride for thin-layer chromatography meeting the following additional specifications.

**Purity** Related substances—Dissolve 5.0 mg of benzoylmesaconine hydrochloride for assay in 5 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of this solution, add the mobile phase to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography ≤2.0 for the following conditions. Determine each peak area of both solutions by the automatic integration method; the total area of the peaks other than the peak of benzoylmesaconine obtained from the sample solution is not larger than the peak area of benzoylmesaconine from the standard solution.

Operating conditions
Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay (3) under Goshajinkigan Extract.

Detector: An ultraviolet absorption photometer (wavelength: 245 nm).

Time span of measurement: About 6 times as long as the retention time of benzoylmesaconine.

System suitability
Test for required detectability: Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 20 mL. Confirm that the peak area of benzoylmesaconine obtained from 20 μL of this solution is equivalent to 3.5 to 6.5% of that of benzoylmesaconine from 20 μL of the standard solution.

System performance: When the procedure is run with 20 μL of aconitum monoester alkaloids standard TS for assay under the above operating conditions, benzoylmesaconine, benzoylhyacoline and 14-anisoylaconine are eluted in this order with the resolution between these peaks being not less than 4, respectively.

System repeatability: When the test is repeated 6 times with 20 μL of aconitum monoester alkaloids standard TS for assay under the above operating conditions, the relative standard deviations of the peak areas of benzoylmesaconine, benzoylhyacoline and 14-anisoylaconine are not more than 1.5%, respectively.

**Benzoylmesaconine hydrochloride for component determination** See benzoylmesaconine hydrochloride for assay.

**Benzoylmesaconine hydrochloride for thin-layer chromatography** C₃₁H₄₃NO₁₀.HCl.₈H₂O White crystals or crystalline powder. Soluble in water and in ethanol (99.5) and sparingly soluble in methanol. Melting point: about 250°C (with decomposition).

Absorbance ≤2.24 E₁%₁₀₀ (230 nm): 217 – 231 (5 mg calculated on the anhydrous basis, methanol, 200 mL).

**Purity** Related substances—Dissolve 1.0 mg of benzoylmesaconine hydrochloride for thin-layer chromatography in exactly 1 mL of ethanol (99.5). Perform the test with 5 μL of this solution as directed in the Identification under Processed Aconite Root: no spot other than the principal spot at around Rf value of 0.4 appears.

**Benzoyl peroxide, 25% water containing** (C₆H₅COOCH₂C₆H₅)₂O. White moist crystals or powder. Soluble in diethylene and in chloroform, and very slightly soluble in water and in ethanol (95). Melting point: 103 – 106°C (dried substance) (with decomposition).

Loss on drying ≤2.41: not more than 30% (0.1 g, in vacuum, silica gel, constant mass).

**Benzyl alcohol** C₆H₅CH₂OH Clear and colorless liquid, having a characteristic odor.

**Specific gravity** ≤2.560 d₂₀°: 1.045 – 1.050.

Preserve in a light-resistant tight container.

**Benzyl benzoate** C₆H₅COOCH₂C₆H₅ A colorless oily liquid. Congealing point: about 18°C. Boiling point: about 323°C.

**Specific gravity** ≤2.560 d₂₀°: 1.118 – 1.123.

Preserve in a light-resistant tight container.

**Benzyl parahydroxybenzoate** HOCH₂H₂COOCH₂C₆H₅ White, odorless, fine crystals or crystalline powder. Freely soluble in ethanol (95), in acetone and in diethylene ether, and very slightly soluble in water.

**Melting point** ≤2.60: 109 – 112°C

**Residue on ignition** ≤2.40: not more than 0.1%.

**Content**: not less than 99.0%.—Assay—Proceed as directed in the Assay under Ethyl Parahydroxybenzoate.

Each mL of 1 mol/L sodium hydroxide VS = 228.2 mg of C₆H₅O₃

**Benzylpenicillin benzathine** See benzylpenicillin benzathine hydrate.

**Benzylpenicillin benzathine hydrate** (C₁₆H₁₆N₂O₁₂S₂)₅.C₁₆H₂₅N₂.H₂O [Same as the namesake
monograph]

Benzylopenicillin potassium C_{16}H_{17}KNO_{5}S [Same as the monograph Benzylpenicillin Potassium]

Benzy l- p-hydroxybenzoate See benzy l parahydroxyben zoate.

p-Benzylphenol C_{12}H_{10}ClCH_{2}OH White to pale yellowish white crystals or crystalline powder.

Melting point <2.60°: 80 – 85°C

Beraprost sodium C_{24}H_{29}NaO_{5} [Same as the namesake monograph]

Beraprost sodium for assay C_{24}H_{29}NaO_{3} [Same as the monograph Beraprost Sodium. When dried it contains not less than 99.0% of beraprost sodium (C_{24}H_{29}NaO_{3}).]

Berberine chloride See berberine chloride hydrate.

Berberine chloride hydrate C_{20}H_{18}ClNO_{4} [Same as the namesake monograph]

Berberine chloride hydrate for thin-layer chromatography See berberine chloride hydrate for thin-layer chromatography.

Berberine chloride hydrate for thin-layer chromatography [Same as the monograph Berberine Chloride Hydrate. Use berberine chloride hydrate for thin-layer chromatography.]

Bergenin for thin-layer chromatography C_{14}H_{16}O_{9} White crystals or crystalline powder. Slightly soluble in ethanol (99.5), very slightly soluble in water, and practically insoluble in diethyl ether.

Identification—Dissolve 10 mg of bergenin in 10 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL of each of the sample solution and standard solution as directed in the Identification (2) under Phellodendron Bark: any spot other than the principal spot from the sample solution is not more intense than the spot from the standard solution.

Bergenin for thin-layer chromatography C_{14}H_{16}O_{9}.xH_{2}O White crystals or crystalline powder. Slightly soluble in ethanol (99.5), very slightly soluble in water, and practically insoluble in diethyl ether.

Identification—Determine the absorption spectrum of a solution of bergenin for thin-layer chromatography in methanol (1 in 50,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>; it exhibits maxima between 217 nm and 221 nm, and between 273 nm and 277 nm, and a minimum between 241 nm and 245 nm.

Purity Related substances—Dissolve 1.0 mg of bergenin for thin-layer chromatography in 20 mL of methanol, and add hexane for purity of crude drug to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 20 μL of this solution and standard solution as directed in the Identification (2) under Phellodendron Bark: any spot other than the principal spot from the sample solution is not more intense than the spot from the standard solution.

Betahistine mesilate C_{12}H_{15}N_{2}.2CH_{3}O_{2}S [Same as the namesake monograph]

Betahistine mesilate for assay [Same as the monograph Betahistine Mesilate. When dried, it contains not less than 99.0% of betahistine mesilate (C_{12}H_{15}N_{2}.2CH_{3}O_{2}S).]

Bezafibrate for assay C_{20}H_{27}CINO_{4} [Same as the monograph Bezafibrate. When dried it contains not less than 99.0% of bezafibrate (C_{20}H_{27}CINO_{4}).]

BGLB Dissolve 10 g of peptone and 10 g of lactose monohydrate in 500 mL of water, add 200 mL of fresh ox bile or a solution prepared by dissolving 20 g of dried ox bile powder in 200 mL of water and adjusted the pH to between 7.0 and 7.5, then add water to make 975 mL, and again adjust to pH 7.4. Then add 13.3 mL of a solution of brilliant green (1 in 1000) and water to make 1000 mL in total volume, and filter through absorbent cotton. Dispense 10 mL portions of the filtrate into tubes for fermentation, and sterilize by autoclaving at 121°C for not more than 20 minutes, then cool quickly, or sterilize fractionally on each of three successive days for 30 minutes at 100°C.

α-BHC (α-Hexachlorocyclohexane) C_{12}H_{13}Cl_{6} Melting point <2.60°: 157 – 159°C

Purity Related substances—Dissolve 10 mg of α-BHC in 5 mL of acetone for purity of crude drug, and add hexane for purity of crude drug to make exactly 100 mL. Pipet 1 mL of this solution, add hexane for purity of crude drug to make exactly 100 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add hexane for purity of crude drug to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 1 μL each of the sample solution and standard solution (1) as directed under Gas Chromatography <2.02> according to the following conditions, and measure each peak area from these solutions by the automatic integration method: the total peak area other than α-BHC from the sample solution is not larger than the peak area of α-BHC from the standard solution (1).

Operating conditions

Proceed the operating conditions in the Purity (2) under Crude Drugs Test <5.01> except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add hexane for purity of crude drug to make 20 mL, and use this solution as standard solution (2). Adjust the detection sensitivity so that the peak area of α-BHC obtained from 1 mL of the standard solution (2) can be measured by the automatic integration method, and the peak height of α-BHC from 1 μL of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About twice as long as the retention time of α-BHC beginning after the peak of solvent.

β-BHC (β-Hexachlorocyclohexane) C_{12}H_{13}Cl_{6} Melting point <2.60°: 308 – 310°C

Purity Related substances—Proceed as directed in the Purity under α-BHC using the following standard solution (1).

Standard solution (1): Pipet 2 mL of the sample solution, and add hexane for purity of crude drug to make exactly 100 mL.

γ-BHC (γ-Hexachlorocyclohexane) C_{12}H_{13}Cl_{6} Melting point <2.60°: 112 – 114°C

Purity Related substances—Proceed as directed in the Purity under α-BHC.

δ-BHC (δ-Hexachlorocyclohexane) C_{12}H_{13}Cl_{6} Melting point <2.60°: 137 – 140°C

Purity Related substances—Proceed as directed in the Purity under α-BHC using the following standard solution (1).

Standard solution (1): Pipet 5 mL of the sample solution, and add hexane for purity of crude drug to make exactly 100 mL.
Bifonazole \( C_{22}H_{18}N_2 \) [Same as the namesake monograph]

Bile salts See Microbial Limit Test for Crude Drugs <5.02>.

**2-(4-Biphenylyl)propionic acid** \( C_{13}H_{14}O_2 \) Light yellowish white powder.

**Melting point** <2.60°: 145 – 148°C

**Purity**—Dissolve 1 mg of 2-(4-biphenylyl) propionic acid in a mixture of water and acetonitrile (11:9) to make 50 mL. Perform the test with 20 μL of this solution as directed under Liquid Chromatography <2.01> according to the operating conditions of the Related substances in the Purity (3) under Flurbiprofen. Determine each peak area of the solution in about twice as long as the retention time of the main peak by the automatic integration method, and calculate the amount of 2-(4-biphenylyl)propionic acid by the area percentage method: it is not less than 98.0%.

**Content:** not less than 98.0%. Assay—Weigh accurately about 0.5 g of 2-(4-biphenylyl)propionic acid, previously dried in vacuum over silica gel for 4 hours, and titrate <2.50° with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of phenolphthalein TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS is 22.63 mg of \( C_{13}H_{14}O_2 \).

**2,2'-Bipyridyl** \( C_{14}H_{8}N_2 \) [K 8486, Special class]

**Bis(cis-3,3,5-trimethylcyclohexyl) phthalate**

\( C_{16}H_{20}I_3N_3O_8 \) White crystalline powder. **Melting point** <2.60°: 91 – 94°C

**Bisdemethoxycurcumin** \( C_{10}H_{12}O_4 \) Yellow to orange crystalline powder. Sparingly soluble in methanol, slightly soluble in ethanol (99.5), and practically insoluble in water.

**Melting point:** 213 – 217°C.

**Identification**—Determine the absorption spectrum of a solution of bisdemethoxycurcumin in methanol (1 in 400000) as directed under Ultraviolet-visible Spectrophotometry <2.24°> it exhibits a maximum between 413 nm and 417 nm.

**Purity** Related substances—(1) Dissolve 4 mg of bisdemethoxycurcumin in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.07°>. Spot 5 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of dichloromethane and methanol (19:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): the spots other than the principal spot at RT value of about 0.3 obtained from the sample solution are not more intense than the spot from the standard solution.

(2) Dissolve 1.0 mg of bisdemethoxycurcumin in 5 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> under the following conditions. Determine each peak from both solutions by the automatic integration method: the total area of the peaks other than the peak of bisdemethoxycurcumin obtained from the sample solution is not larger than the peak area of bisdemethoxycurcumin from the standard solution.

**Operating conditions**

Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay under Turmeric.

**System suitability**

Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of bisdemethoxycurcumin obtained from 10 μL of this solution is equivalent to 3.5 to 6.5% of that of bisdemethoxycurcumin from 10 μL of the standard solution.

**System performance and system repeatability:** Proceed as directed in the operating conditions in the Assay under Turmeric.

**4,4'-Bis(diethylamino)benzophenone**

\( C_{12}H_{12}NCO_2 \) Light yellow crystals.

**Content:** not less than 98%. Assay—Weigh accurately 0.25 g of 4,4'-bis(diethylamino)benzophenone, dissolve in 50 mL of acetic acid (100), and titrate <2.50° with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank titration in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS is 16.22 mg of \( C_{12}H_{12}NCO_2 \).

**N,N'-Bis[2-hydroxy-1-(hydroxymethyl)ethyl]-5-hydroxyacetylamino-2,4,6-triiodoisophthalamide** \( C_{19}H_{16}O_4 \) White crystalline powder.

**Identification** (1) Heat 0.1 g of \( N,N'-bis[2-hydroxy-1-(hydroxymethyl)ethyl]-5-hydroxyacetylamino-2,4,6-triiodoisophthalamide \) over free flame: a purple colored gas evolves.

(2) Determine the infrared absorption spectrum of \( N,N'-bis[2-hydroxy-1-(hydroxymethyl)ethyl]-5-hydroxyacetylamino-2,4,6-triiodoisophthalamide \) over free flame: a purple colored gas evolves.

**Purity**—Dissolve 0.10 g of \( N,N'-bis[2-hydroxy-1-(hydroxymethyl)ethyl]-5-hydroxyacetylamino-2,4,6-triiodoisophthalamide \) in 10 mL of water, and use this solution as the sample solution. Pipet 1 mL of this solution, add water to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak area of both solutions by automatic integration method: the total area of the peaks other than the peak of bisdemethoxycurcumin obtained from the sample solution is not larger than the peak area of bisdemethoxycurcumin from the standard solution.
peak area of N,N'-bis[2-hydroxy-1-(hydroxymethyl)ethyl]-5-hydroxyacetamino-2,4,6-triiodoisophthalamide obtained from the standard solution.

Operating conditions
Proceed the operating conditions in the Purity (6) under Iopamidol.

System suitability
Proceed the system suitability in the Purity (6) under Iopamidol.

Bismuth nitrate See bismuth nitrate pentahydrate.

Bismuth nitrate pentahydrate Bi(NO₃)₃.5H₂O [K 8566, Special class]

Bismuth nitrate-potassium iodide TS Dissolve 0.35 g of bismuth nitrate pentahydrate in 4 mL of acetic acid (100) and 16 mL of water (solution A). Dissolve 8 g of potassium iodide in 20 mL of water (solution B). To 20 mL of a mixture of solution A and solution B (1:1) add 80 mL of dilute sulfuric acid and 0.2 mL of hydrogen peroxide (30). Prepare before use.

Bismuth nitrate TS Dissolve 5.0 g of bismuth nitrate pentahydrate in acetic acid (100) to make 100 mL.

Bismuth potassium iodide TS Dissolve 10 g of l-tartaric acid in 40 mL of water, add 0.85 g of bismuth subnitrate, shake for 1 hour, add 20 mL of a solution of potassium iodide (2 in 5), shake thoroughly, allow to stand for 24 hours, and filter (solution A). Separately, dissolve 10 g of l-tartaric acid in 50 mL of water, add 5 mL of solution A, and preserve in a light-resistant, glass-stoppered bottle.

Bismuth sodium trioxide NaBiO₃ A yellow-brown powder.

Identification—(1) To 10 mg of bismuth sodium trioxide add 5 mL of a solution of manganese (II) nitrate hexahydrate (4 in 125) and 1 mL of diluted nitric acid (1 in 3), and shake vigorously for 10 seconds: a red-purple color is developed.

(2) Dissolve 10 mg of bismuth sodium trioxide in 2 mL of diluted hydrochloric acid (1 in 2): this solution responds to the Qualitative Tests <1.09> (1) for sodium salt.

Bismuth subnitrate [Same as the namesake monograph]

Bismuth subnitrate TS Dissolve 10 g of l-tartaric acid in 40 mL of water, add 0.85 g of bismuth subnitrate, shake for 1 hour, then add 20 mL of a solution of potassium iodide (2 in 5), and shake well. After standing for 24 hours, filter, and preserve the filtrate in a light-resistant bottle.

Bismuth subnitrate-potassium iodide TS for spraying, dilute Dissolve 10 g of l-tartaric acid in 50 mL of water, and add 5 mL of bismuth subnitrate TS.

Bismuth sulfite indicator Prepared for microbial test.

Bisoprolol fumarate for assay (C₁₇H₁₉NO₄)₂.C₄H₇O₄
[Same as the monograph Bisoprolol Fumarate. However, when dried, it contains not less than 99.0% of bisoprolol fumarate (C₁₇H₁₉NO₄)₂.C₄H₇O₄]. Also, when performing the Purity (2) under Bisoprolol Fumarate, the total area of the peaks other than bisoprolol is not larger than 1/5 times the peak area of bisoprolol from the standard solution.

Purify as follows if needed.

Purification method—Dissolve, with heating, 2 g of Bisoprolol Fumarate in 200 mL of ethyl acetate, add 0.5 g of activated carbon, shake well, and filter using a glass filter (G4). Place the filtrate in ice water for 2 hours while occasional shaking. Collect the crystals that precipitate out using a glass filter (G3). Dry the crystals obtained in vacuum at 80°C for 5 hours using phosphorus (V) oxide as a desiccant.

Bis-(1-phenyl-3-methyl-5-pyrazolone) C₁₇H₁₇B₂O₃
White to pale yellow crystals or crystalline powder. It dissolves in mineral acids and in alkali hydroxides, and it does not dissolve in water, in ammonia TS, or in organic solvents. Melting point: not below 300°C.

Nitrogen content <1.08>: 15.5 – 16.5%
Residue on ignition <2.44>: not more than 0.1%.

Bis(1,1-trifluoroacetoxy)iodobenzene C₁₇H₁₇F₂IO₄
Prepared for amino acid analysis or biochemistry.

Bis-trimethyl silyl acetamide CH₃CON[Si(CH₃)₃]₂
Colorless liquid.
Refractive index <2.45> nD20: 1.414 – 1.418
Specific gravity <2.56> d30: 0.825 – 0.835
Boiling point <2.57>: 71 – 73°C

Bitter orange peel [Same as the namesake monograph]

Block buffer solution Dissolve 4 g of blocking agent in 100 mL of water, and add 100 mL of 0.01 mol/L phosphate buffer-sodium chloride TS, pH 7.4.

Blocking agent Powder whose main ingredient is bovine-derived lactoprotein. For immunological research purposes.

Blood agar medium Sterilize 950 mL of heart infusion agar medium under increased pressure. Allow the media to cool to about 50°C, add 50 mL of horse or sheep defibrinated blood, dispense in sterilized Petro dishes, and make them as plate media.

1% blood suspension Wash a defibrinated animal blood in isotonic solution, and make it into suspension to contain 1 vol%. Prepare before use.

Blue tetrazolium C₄₀H₃₂Cl₂N₈O₂ 3,3’-(3,5-diphenyl) tetrazolium chloride] Light yellow crystals. Freely soluble in methanol, in ethanol (95) and in chloroform, slightly soluble in water, and practically insoluble in acetone and in ether. Melting point: about 245°C (with decomposition).

Absorbance <2.24> E₁%cm (252 nm): not less than 826 (methanol).

Blue tetrazolium TS, alkaline To 1 volume of a solution of blue tetrazolium in methanol (1 in 200) add 3 volumes of a solution of sodium hydroxide in methanol (3 in 25). Prepare before use.

Borane-pyridine complex C₅H₈BN
Content: not less than 80%. Assay—Accurately weigh about 30 mg of borane-pyridine complex, dissolve in 40 mL of 0.05 mol/L iodide solution, add 10 mL of diluted sulfuric acid (1 in 6), and titrate <2.50> with 0.1 mol/L sodium thiosulfate VS (indicator: starch TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium thiosulfate VS = 1.549 mg of C₅H₈BN

Borate-hydrochloric acid buffer solution, pH 9.0 Dis-
solve 19.0 g of sodium borate in 900 mL of water, adjust the pH to exactly 9.0 with 1 mol/L hydrochloric acid TS, and add water to make 1000 mL.

Borax See sodium tetraborate decahydrate.

Boric acid $\text{H}_3\text{BO}_3$ [K 8863, Special class]

Boric acid-magnesium chloride buffer solution, pH 9.0
Dissolve 3.1 g of boric acid in 210 mL of dilute sodium hydroxide, and add 10 mL of magnesium chloride hexahydrate (1 in 50) and water to make 1000 mL. Adjust the pH to 9.0, if necessary.

Boric acid-methanol buffer solution Weigh exactly 2.1 g of boric acid, dissolve in 28 mL of sodium hydroxide TS, and add 36 mL of 0.2 mol/L sodium hydroxide VS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 9.0
To 50 mL of 0.2 mol/L boric acid-0.2 mol/L potassium chloride TS for buffer solution add 21.30 mL of 0.2 mol/L sodium hydroxide VS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 9.2
To 50 mL of 0.2 mol/L boric acid-0.2 mol/L potassium chloride TS for buffer solution add 26.70 mL of 0.2 mol/L sodium hydroxide VS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 9.6
To 50 mL of 0.2 mol/L boric acid-0.2 mol/L potassium chloride TS for buffer solution add 36.85 mL of 0.2 mol/L sodium hydroxide VS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 10.0
To 50 mL of 0.2 mol/L boric acid-0.2 mol/L potassium chloride TS for buffer solution add 43.90 mL of 0.2 mol/L sodium hydroxide VS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 10.2
To 50 mL of 0.2 mol/L boric acid-0.2 mol/L potassium chloride TS for buffer solution add 50 mL of 0.2 mol/L sodium hydroxide VS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 10.4
Dissolve 12.376 g of boric acid and 24.736 g of boric acid in 0.1 mol/L sodium hydroxide TS and water to make 200 mL.

Boric acid-potassium chloride-sodium hydroxide buffer solution, pH 10.6
Dissolve 19.0 g of sodium borate in 900 mL of water, adjust the pH to exactly 9.0 with 1 mol/L hydrochloric acid TS, and add water to make 1000 mL.

Borate

Bradykinin $\text{C}_8\text{H}_{17}\text{N}_2\text{O}_{11}$ A white powder. Freely soluble in water and in acetic acid (31), and practically insoluble in diethyl ether. Optical rotation $<2.49\text{ }^\circ$ $[\alpha]_D^20: -80$ to $-90^\circ$ (15 mg, water, 5 mL, 100 mm).
**Purity** Related substances—Dissolve 2.0 mg of bradykinin in 0.2 mL of water, and use this solution as the sample solution. Perform the test with the sample solution as directed under Thin-layer Chromatography 〈2.02〉. Prepare 5 μL of the sample solution on a plate of cellulose for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water, pyridine and acetic acid (31:15:12:10:3) to a distance of about 10 cm, and dry the plate at 60°C. Spray evenly a solution of ninhydrin in 1-butanol (1 in 1000) on the plate, and heat at 60°C for 30 to 60 minutes: any spot other than the principal spot arisen from bradykinin does not appear.

**Brilliant green** C₂₇H₃₄N₂O₄S Fine, glistening, yellow crystals. It dissolves in water and in ethanol (95). The wavelength of absorption maximum: 623 nm.

**Bromine** Br [K 8529, Special class]

**Bromine-acetic acid TS** Dissolve 10 g of sodium acetate trihydrate in acetic acid (100) to make 100 mL, add 5 mL of bromine, and shake. Preserve in light-resistant containers, preferably in a cold place.

**Bromine-carbon tetrachloride TS** To 0.1 g of bromine add carbon tetrachloride to make 100 mL, and dilute a 2 mL portion of this solution with carbon tetrachloride to make 100 mL. Prepare before use.

**Bromine-cyclohexane TS** Dissolve 0.1 g of bromine in cyclohexane to make 100 mL. To 2 mL of this solution add cyclohexane to make 10 mL. Prepare before use.

**Bromine-sodium hydroxide TS** To 100 mL of a solution of sodium hydroxide (3 in 100) add 0.2 mL of bromine. Prepare before use.

**Bromine TS** Prepare by saturating water with bromine as follows: Transfer 2 to 3 mL of bromine to a glass-stoppered bottle, the stopper of which should be lubricated with petrolatum, add 100 mL of cold water, insert the stopper, and shake. Preserve in light-resistant containers, preferably in a cold place.

**Bromocresol green** C₂₁H₁₄Br₄O₅S [K 8840, Special class]

**Bromocresol green-sodium hydroxide TS** Triturate 0.2 g of bromocresol green with 2.8 mL of 0.1 mol/L sodium hydroxide VS in a mortar, add water to make 200 mL, and filter if necessary.

**Bromocresol green TS** Dissolve 50 mg of bromocresol green in 100 mL of ethanol (95), and filter if necessary.

**Bromocresol purple** C₁₂H₁₆Br₂O₅S [K 8841, Special class]

**Bromocresol purple-dipotassium hydrogenphosphatocitric acid TS** Mix 30 mL of bromocresol purple-sodium hydroxide TS and 30 mL of dibasic potassium phosphate-citric acid buffer solution, pH 5.3, and wash with three 60-mL portions of chloroform.

**Bromocresol purple-sodium hydroxide TS** Triturate 0.4 g of bromocresol purple with 6.3 mL of dilute sodium hydroxide TS in a mortar, add water to make 250 mL, and filter if necessary.

**Bromocresol purple TS** Dissolve 0.05 g of bromocresol purple in 100 mL of ethanol (95), and filter if necessary.

**Bromophenol blue** C₁₉H₁₀Br₄O₅S [K 8844, Special class]

**Bromophenol blue-potassium biphthalate TS** Dissolve 0.1 g of bromophenol blue in potassium biphthalate buffer solution, pH 4.6, to make 100 mL.

**Bromophenol blue TS** Dissolve 0.1 g of bromophenol blue in 100 mL of dilute ethanol, and filter if necessary.

**0.05% Bromophenol blue TS** Dissolve 0.01 g of bromophenol blue in water to make 20 mL.

**Bromophenol blue TS, dilute** Dissolve 0.05 g of bromophenol blue in 100 mL of ethanol (99.5). Prepare before use.

**Bromophenol blue TS, pH 7.0** Mix 10 mL of bromophenol blue TS and 10 mL of ethanol (95), and adjust the pH to 7.0 with dilute sodium hydroxide TS.

**N-Bromosuccinimide** C₇H₇BrNO₂ [K 9553, Special class]

**N-Bromosuccinimide TS** Dissolve 1 g of N-bromosuccinimide in 1000 mL of water.

**Bromothymol blue** C₂₂H₂₃Br₂O₂S [K 8842, Special class]

**Bromothymol blue-sodium hydroxide TS** To 0.2 g of powdered bromothymol blue add 5 mL of dilute sodium hydroxide TS and a small quantity of water, dissolve by shaking in a water bath at 50°C, then add water to make 100 mL.

**Bromothymol blue-sodium hydroxide-ethanol TS** Dissolve 50 mg of bromothymol blue in 4 mL of diluted 0.2 mol/L sodium hydroxide TS (1 in 10) and 20 mL of ethanol (99.5), and add water to make 100 mL.

**Bromothymol blue TS** Dissolve 0.1 g of bromothymol blue in 100 mL of dilute ethanol, and filter if necessary.

**Bromovalerylurea** C₈H₁₁BrN₂O₂ [Same as the name-sake monograph]

**Brucine** See brucine n-hydrate.

**Brucine dihydrate** See brucine n-hydrate.
Brucine n-hydrate \( \text{C}_2\text{H}_{10}\text{N}_4\text{O}_2\cdot n\text{H}_2\text{O} \) [K 8832, Special class]

B-type erythrocyte suspension Prepare a suspension containing 1 vol% of erythrocyte separated from human B-type blood in isotonic sodium chloride solution.

Bucillamine \( \text{C}_7\text{H}_{12}\text{NO}_3\text{S}_2 \) [Same as the namesake monograph]

Bucillamine for assay \( \text{C}_7\text{H}_{12}\text{NO}_3\text{S}_2 \) [Same as the monograph Bucillamine. However, when dried, it contains not less than 99.0% of bucillamine \( (\text{C}_7\text{H}_{12}\text{NO}_3\text{S}_2) \). Furthermore, it conforms to the following test.]

Purity Related substances—Dissolve 60 mg of bucillamine for assay in 20 mL of a mixture of water and methanol (1:1) and use this solution as the sample solution. Pipet 1 mL of this solution, add the mixture of water and methanol (1:1) to make exactly 100 mL, and use this solution as the standard solution. When the test is performed according to the Purity (3) under Bucillamine, the total area of the peaks other than the bucillamine peak from the sample solution is not larger than the peak area of bucillamine from the standard solution.

Bufalin for assay \( \text{C}_2\text{H}_3\text{O}_6\cdot x\text{H}_2\text{O} \) White, odorless, crystalline powder.

Absorbance \(<2.24\times 10^{-1}\%\) (300 nm): 143 – 153 (10 mg, methanol, 250 mL). Use the sample dried in a desiccator (silica gel) for 24 hours for the test.

Purity Related substances—Dissolve 40 mg of bufalin for assay in 5 mL of chloroform and use this solution as the sample solution. Pipet 1 mL of the sample solution, add chloroform to make exactly 100 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography \(<2.03\times 10^{-1}\%\). Spot 5 \( \mu L \) each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of cyclohexane, acetone and chloroform (4:3:3) to a distance of about 14 cm, and air-dry. Spray evenly sulfuric acid, and heat at 100°C for 2 to 3 minutes: any spot other than the principal spot obtained from the sample solution is not larger and not more intense than the peak area from the standard solution.

Content: not less than 99.0%. Assay—Weigh accurately about 10 mg of bufalin for assay, previously dried in a desiccator (silica gel) for 24 hours, dissolve in methanol to make exactly 10 mL, and use this solution as the sample solution. Perform the test with 20 \( \mu L \) of the sample solution as directed under Liquid Chromatography \(<2.07\times 10^{-1}\%\) according to the following conditions. Measure the peak area by the automatic integration method, and calculate the amount of bufalin by the area percentage method.

Operating conditions
Detector: An ultraviolet absorption photometer (wavelength: 300 nm).

Column: A stainless steel column 4 to 6 mm in inside diameter and 15 to 30 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 to 10 \( \mu m \) in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of water and acetonitrile (1:1).

Flow rate: Adjust the flow rate so that the retention time of bufalin is about 6 minutes.

Selection of column: Dissolve 0.01 g each of bufalin for assay, cinobufagin for assay and resibufogenin for assay in methanol to make 200 mL. Proceed with 20 \( \mu L \) of this solution according to the above conditions. Use a column giving elution of bufalin, cinobufagin and resibufogenin in this order and completely resolving these peaks.

Detection sensitivity: Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution (1). Pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of bufalin obtained from 20 \( \mu L \) of the standard solution (2) can be measured by the automatic integration method, and the peak height of bufalin from 20 \( \mu L \) of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About twice as long as the retention time of bufalin beginning after the solvent peak.

Bufalin for component determination See bufalin for assay.

Buffer solution for celmoleukin Combine 12.5 mL of 0.5 mol/L tris buffer solution, pH 6.8, 10 mL of sodium lauryl sulfate solution (1→10), 10 mL of glycerin, and 17.5 mL of water, shake, and then add and dissolve 5 mg of bromophenol blue.

Storage—Store in a cool place, shielded from light.

Buformin hydrochloride for assay \( \text{C}_8\text{H}_{12}\text{N}_2\text{HCl} \) [Same as the monograph Buformin Hydrochloride. When dried, it contains not less than 99.5% of buformin hydrochloride (\( \text{C}_8\text{H}_{12}\text{N}_2\text{HCl} \)).]

n-Butanol See 1-butanol.

sec-Butanol See 2-butanol.

1-Butanol \( \text{CH}_3(\text{CH}_2)_2\text{CH}_2\text{OH} \) [K 8810, Special class]

2-Butanol \( \text{CH}_3\text{CH}_2\text{CH}(\text{OH})\text{CH}_3 \) [K 8812, Special class]

2-Butanone \( \text{CH}_3\text{COC}_2\text{H}_3 \) [K 8900, Special class]

Butenafine hydrochloride for assay \( \text{C}_2\text{H}_3\text{N}_2\text{HCl} \) [Same as the monograph Butenafine Hydrochloride]

\( \text{N}-\text{t}-\text{Butoxytocarboxyl}-1\text{-glutamic acid-}\alpha\text{-phenyl ester} \) \( \text{C}_{16}\text{H}_{29}\text{NO}_4 \) White powder.

Melting point \(<2.60\times 95-104^\circ\text{C}\)

Purity Related substances—Dissolve 10 mg of \( \text{N}-\text{t}-\text{butoxytocarboxyl}-1\text{-glutamic acid-}\alpha\text{-phenyl ester} \) in 5 mL of dilute ethanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add dilute ethanol to make exactly 50 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography \(<2.05\times\) according to the following conditions. Measure the peak area by the automatic integration method, and calculate the amount of butenafine hydrochloride on the standard solution on three plates of silica gel with fluorescent indicator for thin-layer chromatography. Develop the first plate with a mixture of chloroform, ethyl acetate and acetic acid (100) (25:25:1), the second plate with a mixture of benzene, 1,4-dioxane and acetic acid (100) (95:25:4), and the third plate with a mixture of chloroform, methanol and acetic acid (100) (45:4:1) to a distance of about 12 cm, and air-dry these plates. Examine under ultraviolet light (main wavelength: 254 nm); the spots other than the principal spot obtained from the sample solution are not more intense than the spot from the standard so-
lution in all plates.

**n-Butyl acetate** CH₃COOCH₂CH₂CH₃CH₃ [K 8377, Special class]

**t-Butyl alcohol** (CH₃)₃COH A crystalline solid, having a characteristic odor. A colorless liquid at above an ordinary temperature.

Specific gravity <2.56> d₂₀°: about 0.78; Boiling point: about 83°C; Melting point: about 25°C.

Identification—Determine the infrared absorption spectrum as directed in the liquid film method as directed under Infrared Spectrophotometry <2.25> it exhibits absorption at the wave numbers of about 3370 cm⁻¹, 2970 cm⁻¹, 1471 cm⁻¹, 1202 cm⁻¹, 1022 cm⁻¹, 913 cm⁻¹ and 749 cm⁻¹.

**n-Butylamine** CH₃CH₂CH₂CH₂NH₂ A colorless liquid, having an amine-like, characteristic odor. Miscible with water, with ethanol (95) and with diethyl ether. The solution in water shows alkalinity and rapidly absorbs carbon dioxide from the air.

Specific gravity <2.56> d₂₀°; 0.740 - 0.747
Distilling range <2.57>: 76.5 - 79°C, not less than 96 vol.%

**Butyl benzoate** C₆H₅COOCH₂CH₂CH₃CH₃ A clear and colorless liquid.

Refractive index <2.45> nD₂₀: 1.495 - 1.500
Specific gravity <2.56> d₁₅°: 1.066 - 1.013

**n-Butyboronic acid** CH₃H₂BO₂ White flakes.
Melting point <2.60>: 90 - 92°C

**n-Butyl chloride** See 1-chlorobutane.

**n-Butyl formate** HCOO(CH₂)₃CH₃ Clear and colorless liquid, having a characteristic odor.
Specific gravity <2.56> d₂₀°: 0.884 - 0.904

**tert-Butyl methyl ether** (CH₃)₂COCH₃ Clear colorless liquid, having a specific odor.
Refractive index <2.45> nD₂₀: 1.3689
Specific gravity <2.56> d₁₅°: 0.7404

**Butyl parahydroxybenzoate** HOCH₃COOCH₂CH₂CH₂CH₃ [Same as the namesake monograph]

**Butyrolactone** C₄H₇O₂ Clear, colorless to practically colorless liquid.
Specific gravity <2.56> d₁₅°: 1.128 - 1.135
Boiling point <2.57>: 198 - 208°C

**Cadmium acetate** See cadmium acetate dihydrate.

**Cadmium acetate dihydrate** Cd(CH₃COO)₂·2H₂O White crystals or crystalline powder.

Identification—(1) Dissolve 0.2 g of cadmium acetate dihydrate in 20 mL of water, and use this as the sample solution. To 10 mL of the sample solution add 2 mL of iron (III) chloride TS: a red-brown color is produced.

(2) To 10 mL of the sample solution obtained in (1) add 1 mL of sodium sulfide TS: a yellow precipitate is produced.

**Cadmium ground metal** Cd [H 2113, First class]

**Cadmium-ninhydrin TS** Dissolve 0.05 g of cadmium acetate dihydrate in 5 mL of water and 1 mL of acetic acid (100), add 2-butanol to make 50 mL, and dissolve 0.1 g of ninhydrin in this solution. Prepare before use.

**Cadralazine for assay** C₁₂H₁₇N₂O₃ [Same as the monograph Cadralazine. When dried, it contains not less than 99.0% of cadralazine (C₁₂H₁₇N₂O₃).]

**Caffeine** See caffeine hydrate.

**Caffeine hydrate** C₈H₁₀N₄O₂·H₂O [Same as the namesake monograph]

**Caffeine, anhydrous** C₈H₁₀N₄O₂ [Same as the monograph Anhydrous Caffeine]

**Calcium acetate monohydrate** (CH₃COO)₂Ca·H₂O [K 8364, Special class]

**Calcium carbonate** CaCO₃ [K 8617, Special class]

**Calcium carbonate for assay** CaCO₃ [Same as the monograph Precipitated Calcium Carbonate. When dried, it contains not less than 99.0% of calcium carbonate (CaCO₃).]

**Calcium chloride** See calcium chloride dihydrate.

**Calcium chloride dihydrate** CaCl₂·2H₂O [K 8122, Special class]

**Calcium chloride for drying** CaCl₂ [K 8124, For drying]

**Calcium chloride for Karl Fischer method** CaCl₂ [K 8125, For water determination]

**Calcium chloride TS** Dissolve 7.5 g of calcium chloride dihydrate in water to make 100 mL (0.5 mol/L).

**Calcium gluconate for thin-layer chromatography** See calcium gluconate hydrate for thin-layer chromatography.

**Calcium gluconate hydrate for thin-layer chromatography** [Same as the monograph Calcium Gluconate Hydrate. When the test is performed as directed in the Identification (1) under Calcium Gluconate Hydrate, no spot other than the principal spot appears.]

**Calcium hydroxide** Ca(OH)₂ [K 8575, Special class]

**Calcium hydroxide for pH determination** Calcium hydroxide prepared for pH determination.

**Calcium hydroxide pH standard solution** See pH Determination <2.54>.

**Calcium hydroxide TS** To 3 g of calcium hydroxide add 1000 mL of cold distilled water, and occasionally shake the mixture vigorously for 1 hour. Allow to stand, and use the supernatant liquid (0.04 mol/L).

**Calcium nitrate** See calcium nitrate tetrahydrate.

**Calcium nitrate tetrahydrate** Ca(NO₃)₂·4H₂O [K 8549, Special class]

**Calcium oxide** CaO [K 8410, Special class]

**Calcium paraaminosalicylate hydrate for assay** C₇H₅CaNO₃·3½H₂O [Same as the monograph Calcium Paraaminosalicylate Hydrate. It contains not less than 99.0% of calcium paraaminosalicylate (C₇H₅CaNO₃), calculated on the anhydrous basis.]

**Camphor** C₈H₁₀O [Same as the monograph d-Camphor or dl-Camphor]
**d-Camphorsulfonic acid** $\text{C}_{10}\text{H}_{18}\text{O}_5\text{S}$ White crystals or crystalline powder, having a characteristic odor. Very soluble in water, and soluble in chloroform.

**Purity** Clarity and color of solution—Dissolve 1.0 g of d-camphorsulfonic acid in 10 mL of water: the solution is clear and colorless or pale yellow.

Loss on drying $<2.4\%$: not more than 2.0% (1 g, 105°C, 5 hours).

Content: not less than 99.0%, calculated on the dried basis. Assay—Weigh accurately about 4 g of d-camphorsulfonic acid, dissolve in 50 mL of water, and titrate $<2.50\%$ with 1 mol/L sodium hydroxide VS (indicator: 3 drops of methyl red TS). Perform a blank determination in the same manner.

Each mL of 1 mol/L sodium hydroxide VS $= 232.3$ mg of $\text{C}_{10}\text{H}_{18}\text{O}_5\text{S}$

**Candesartan cilexetil** for assay $\text{C}_{33}\text{H}_{34}\text{N}_6\text{O}_6$ [Same as the monograph Candesartan Cilexetil. It contains not less than 99.5% of candesartan cilexetil ($\text{C}_{33}\text{H}_{34}\text{N}_6\text{O}_6$), calculated on the anhydrous basis, and when performed the test as directed in the Purity (2) under Candesartan Cilexetil, the total area of the peaks other than candesartan cilexetil obtained from the sample solution is not larger than 1/2 times the peak area of candesartan cilexetil from the standard solution.]

**Caprylic acid** $\text{CH}_{3}(\text{CH}_{2})_6\text{COOH}$ A clear and colorless oily liquid, having a slight unpleasant odor. Freely soluble in ethanol (95) and in chloroform, and very slightly soluble in water.

Refractive index $<2.45$ $n_\text{D}^\circ: 1.426 – 1.430$

Specific gravity $<2.56$ $d_\text{D}^\circ: 0.908 – 0.912$

Distilling range $<2.57$: 238 – 242°C, not less than 95 vol%.

**Capsaicin for assay** See (E)-capsaicin for assay.

(E)-**Capsaicin** for assay $\text{C}_{18}\text{H}_{27}\text{NO}_3$ Use (E)-capsaicin for thin-layer chromatography meeting the following additional specifications.

Absorbance $<2.48$: $E_{1\text{cm}}^{1\text{%
mL of this solution} is not larger than 1/2 times the peak area of capsaicin from the standard solution.

Operating conditions
Detector, column, column temperature, mobile phase, and flow rate: Proceed the operating conditions in the Assay under Capsicum.

Time span of measurement: About 3 times as long as the retention time of capsaicin beginning after the solvent peak.

System suitability
System performance, and system repeatability: Proceed the system suitability in the Assay under Capsicum.

Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of capsaicin from 20 μL of this solution is equivalent to 3.5 to 6.5% of that of capsaicin from 20 μL of the standard solution.

(E)-**Capsaicin for component determination** See (E)-capsaicin for assay.

**Capsaicin for thin-layer chromatography** See (E)-capsaicin for thin-layer chromatography.

(E)-**Capsaicin for thin-layer chromatography** $\text{C}_{18}\text{H}_{27}\text{NO}_3$ White crystals, having a strong irritative odor. Very soluble in methanol, freely soluble in ethanol (95) and in diethyl ether, and practically insoluble in water.

Melting point $<2.60\%$: 65 – 70°C

Purity Related substances—Dissolve 20 mg of (E)-capsaicin for thin-layer chromatography in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed in the Identification under Capsicum: any spot other than the principal spot (Rf value is about 0.5) from the sample solution is not more intense than the spot from the standard solution.

**Carbazochrome** $\text{C}_{10}\text{H}_{12}\text{N}_4\text{O}_3$ Yellow-red to red crystals or crystalline powder. Melting point: about 222°C (with decomposition).

Content: not less than 98.0%. Assay—Dissolve about 0.2 g of carbazochrome, previously weighed accurately, in 20 mL of acetic acid (100) by heating, add 80 mL of acetic anhydride, cool, and titrate $<2.50\%$ with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS $= 23.62$ mg of $\text{C}_{10}\text{H}_{12}\text{N}_4\text{O}_3$

**Carbazochrome sodium sulfonate for component determination** See carbazochrome sodium sulfonate trihydrate.

**Carbazochrome sodium sulfonate trihydrate** $\text{C}_{10}\text{H}_{14}\text{Na}_2\text{O}_5\text{S}_3\text{H}_2\text{O}$ [Same as the monograph Carbazochrome Sodium Sulfonate Hydrate. It contains not less than 99.0% of carbazochrome sodium sulfonate ($\text{C}_{10}\text{H}_{14}\text{Na}_2\text{O}_5\text{S}_3$), calculated on the anhydrous basis, and meets the following additional requirement.]

Water $<2.48\%$: 14.0 – 15.0%

**Carbazole** $\text{C}_{12}\text{H}_8\text{N}$ White to nearly white floccose or plate-like crystals or crystalline powder. Freely soluble in pyridine and in acetone, slightly soluble in ethanol (99.5), and practically insoluble in water. It readily sublimes when heated.

Melting point $<2.60\%$: 243 – 245°C

Purity Clarity and color of solution—To 0.5 g of carbazole add 20 mL of ethanol (99.5), and dissolve by warming: the solution is clear.

Residue on ignition: Not more than 0.1% (1 g).

**Carbazole TS** Dissolve 0.125 g of carbazole in ethanol (99.5) to make 100 mL.

0.1 mol/L Carbonate buffer solution, pH 9.6 Dissolve
3.18 g of anhydrous sodium carbonate and 5.88 g of sodium hydrogen carbonate in water to make 1000 mL.

Carbon dioxide CO₂ [Same as the namesake monograph]

Carbon disulfide CS₂ [K 8732, Special class]
Preserve in tightly stoppered containers in a dark, cold place, remote from fire.

Carbonic anhydrase White powder. Derived from bovine RBC. Molecular weight about 29,000.

Carbon monoxide CO A toxic, colorless gas. Prepare by passing the gas generated by reacting formic acid with sulfuric acid through a layer of sodium hydroxide TS. Carbon monoxide from a metal cylinder may be used.

Carbon tetrachloride CCl₄ [K 8459, Special class]

Carvedilol for assay C₁₈H₂₆N₂O₄ [Same as the monograph Carvedilol]

Casein, milk A white to light yellow powder or grain.

Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method as directed under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 1650 cm⁻¹, 1540 cm⁻¹ and 1250 cm⁻¹.

Casein (milk origin) See casein, milk.

Casein peptone See peptone, casein.

Castor oil [Same as the namesake monograph]

Catechol C₆H₄(OH)₂ White crystals.

Melting point <2.60°: 104 – 107°C.

Preserve in a light-resistant tight container.

Cefadroxil C₁₆H₁₇N₃O₅S [Same as the namesake monograph]

Cefadroxil propylene glycolate

Cefadroxil for assay C₁₆H₁₇N₃O₅S [Same as the namesake monograph]

Cefepine pivoxil hydrochloride

Cefepine pivoxil hydrochloride hydrate

Cefepine pivoxil hydrochloride hydrate

Cefdinir lactam ring-cleavage lactones

Cefdinir lactam ring-cleavage lactones

Cetiostatin sodium C₁₄H₁₅N₅O₆S₂ A white to yellow powder. A mixture of diastereoisomers.

Identification—Determine the infrared absorption spectrum of cefdinir lactam ring-cleavage lactones as directed in the Paste method under Infrared Spectrophotometry of cefdinir lactam ring-cleavage lactones as directed in the Paste method under Infrared Spectrophotometry.

Content: not less than 95%. Assay—Dissolve about 5 mg of cefdinir lactam ring-cleavage lactones in 5 mL of 0.1 mol/L phosphate buffer solution, pH 7.0, and use this solution as the sample solution. Perform the test with 5 µL of the sample solution as directed in the operating conditions of the Purity (2) Related substances under Cefdinir, and calculate the areas of each peak by the automatic integration method. Determine the percent of the total peak area of 4 cefdinir lactam ring-cleavage lactones to the total area of all peaks.

Cell suspension solution for teclemoleukin Centrifuge for 5 minutes at 1000 r.p.m culture medium of NK-7 cells that have been cultured statically for 2 to 4 hours. Remove the supernatant by aspiration, and add culture medium for assay of teclemoleukin to a cell concentration of 2 to 4 x 10⁶ cells/mL.

Celmoleukin for liquid chromatography C_{693}H_{1118}N_{178}O_{203}S_{7} [Same as the monograph Celmoleukin (Genetical Recombination). However, contains 0.5 to 1.5 mg of protein per mL, polymers amount for 0.5% or less, and conforms to the following test].

Identification (1) When the amino acid sequence is investigated using the Edman technique and liquid chromatography, the amino acids are detected in the following sequence: alanine, proline, threonine, serine, serine, serine, threonine, lysine, lysine, threonine, glutamine, leucine, glutamine, leucine, and glutamic acid. Also, based on the results of the protein content determination test, place an amount of celmoleukin equivalent to about 0.3 mg in a hydrolysis tube, evaporate to dryness under vacuum, and then add 100 µL of hydrazine anhydride for amino acid sequence analysis. Reduce the internal pressure of the hydrolysis tube by heating for 6 hours at about 100°C. After evaporating to dryness under vacuum, add 250 µL of water to dissolve the residue. To this add 200 µL of benzaldehyde, shake occasionally, leave for one hour, centrifuge, and remove the aqueous layer. Add 250 µL of water to the benzaldehyde layer, shake, centrifuge, combine the aqueous layers, and evaporate to dryness under vacuum. Threonine is detected when amino acid analysis is conducted using the postcolumn technique with ninhydrin on a solution of the residue dissolved by adding 100 µL of 0.02 mol/L hydrochloric acid TS.

(2) Add 1 mL of protein digesting enzyme solution to 1 mL of celmoleukin, shake, and leave for 18 to 24 hours at 37°C. Pipet 1 mL of this solution and add 25 µL of trifluoroacetic acid (1 in 10). To another 1 mL, add 10 µL of 2-mercaptoethanol, leave for 30 minutes at 37°C, and then add 25 µL of trifluoroacetic acid (1 in 10). Perform Liquid Chromatography <2.07> on these two solutions separately under the conditions outlined in Celmoleukin (Genetical Recombination), Identification (4). Repeatedly pipet the celmoleukin derived peak fraction that elutes and when the test is performed according to Celmoleukin (Genetical Recombination), Identification (2), except for the lysines in positions 9 and 49 from the amino terminal amino acid, a peptide estimated from the complete primary structure is detected.

Cephaleine hydrobromate C_{29}H_{34}N_{2}O_{4}.2HBr.xH₂O A white or light-yellow crystalline powder.

Purity—Dissolve 10 mg in 10 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 10 mL, and use this solution as the standard solution. Perform the test with exactly 10 µL each of the sample solution and standard solution as directed in the Assay under Ipecac: when measure the peak areas 2 times as long as the retention time of emetine, the total area of the peaks other than cephaleine is not larger than the peak area of cephaleine from the standard solution.

Ceric ammonium sulfate See cerium (IV) tetraammonium sulfate dihydrate.

Ceric ammonium sulfate-phosphoric acid TS See cerium
Powder. Very soluble in water, and freely soluble in ethanol.

Ceric ammonium sulfate TS See cerium (IV) tetraammonium sulfate TS.

Cerium (III) nitrate hexahydrate Ce(NO₃)₂.6H₂O A colorless or light yellow, crystalline powder. It dissolves in water.

Purity (1) Chloride <1.03%; not more than 0.036%.
(2) Sulfate <1.14%; not more than 0.120%.

Content: not less than 98.0%. Assay—To about 1.5 g of cerous nitrate, accurately weighed, add 5 mL of sulfuric acid, and heat until white fumes are evolved vigorously. After cooling, add 200 mL of water, 0.5 mL of 0.1 mol/L silver nitrate VS, dissolve 5 g of ammonium peroxodisulfate, dissolve, and boil it for 15 minutes. After cooling, add 2 drops of 1,10-phenanthroline TS, and titrate with 0.1 mol/L ferrous ammonium sulfate VS until the pale blue color of the solution changes to red.

Each mL of 0.1 mol/L ferrous ammonium sulfate VS = 43.42 mg of Ce(NO₃)₂.6H₂O

Cerium (III) nitrate TS Dissolve 0.44 g of cerium (III) nitrate hexahydrate in water to make 1000 mL.

Cerium (IV) diammonium nitrate Ce(NH₄)₂(NO₃)₆ [K 8556, Special class]

Cerium (IV) diammonium nitrate TS Dissolve 6.25 g of cerium (IV) diammonium nitrate in 160 mL of diluted dilute nitric acid (9 in 50). Use within 3 days.

Cerium (IV) sulfate tetrahydrate Ce(SO₄)₂·4H₂O [K 8976, Special class]

Cerium (IV) tetraammonium sulfate dihydrate Ce(SO₄)₂·2(NH₄)₂SO₄·2H₂O [K 8976, Special class]

Cerium (IV) tetraammonium sulfate-phosphoric acid TS Dissolve 0.1 g of cerium (IV) tetraammonium sulfate in diluted phosphoric acid (4 in 5) to make 100 mL.

Cerium (IV) tetrammonium sulfate-phosphoric acid TS Dissolve 0.44 g of cerium (IV) tetrammonium sulfate in diluted sulfuric acid (3 in 5) to make 100 mL.

Cerox nitrate See cerium (III) nitrate hexahydrate.

Cerox nitrate TS See cerium (III) nitrate TS.

Cesium chloride CsCl White crystals or crystalline powder. Very soluble in water, and freely soluble in ethanol (99.5).

Loss on drying <2.41%; Not more than 1.0% (1 g, 110°C, 2 hours).

Content: not less than 99.0%. Assay—Weigh accurately about 0.5 g, previously dried, and dissolve in water to make exactly 200 mL. Pipet 20 mL of this solution, add 30 mL of water, and titrate <2.50> with 0.1 mol/L silver nitrate VS (indicator: fluorescein sodium TS).

Each mL of 0.1 mol/L silver nitrate VS = 16.84 mg of CsCl

Cesium chloride TS To about 0.5 g of cesium chloride add water to make 1000 mL.

Cetanol [Same as the namesake monograph]

Cetirizine hydrochloride for assay C₂₁H₂₂ClN₂O₃·2HCl [Same as the monograph Cetirizine Hydrochloride. When dried, it contains not less than 99.5% of cetirizine hydrochloride (C₁₂H₁₈ClN₂O₂·2HCl).

Cetirizine hydrochloride for assay C₂₁H₂₂ClN₂O₃·2HCl [Same as the monograph Cetirizine Hydrochloride. When dried, it contains not less than 99.5% of cetirizine hydrochloride (C₁₂H₁₈ClN₂O₂·2HCl).]
spot other than the principal spot at the Rf value of about 0.4 does not appear.

**Chlomotropic acid** See disodium chlomotropate dihydrate.

**Chlomotropic acid TS** Dissolve 0.05 g of disodium chlomotropate dihydrate in the solution prepared by cautiously adding 68 mL of sulfuric acid to 30 mL of water, cooling, then adding water to make 100 mL. Preserve in light-resistant containers.

**Chlomotropic acid TS, concentrated** Suspend 0.5 g of disodium chlomotropate dihydrate in 50 mL of sulfuric acid, centrifuge, and use the supernatant liquid. Prepare before use.

**Chloral hydrate** CCl₃CH(OH)₂ [Same as the namesake monograph]

**Chloral hydrate TS** Dissolve 5 g of chloral hydrate in 3 mL of water.

**Chloramine** See sodium toluensulfonchloramide trihydrate.

**Chloramphenicol** C₁₆H₁₄ClN₃O₂ [Same as the monograph Chloramphenicol]

**Chlorauric acid** See hydrogen tetrachloroaurate (III) tetrahydrate.

**Chlorauric acid TS** See hydrogen tetrachloroaurate (III) tetrahydrate TS.

**Chlordiazepoxide** C₁₆H₁₄ClN₃O₂ [Same as the namesake monograph]

**Chlordiazepoxide for assay** C₁₆H₁₄ClN₃O₂ [Same as the monograph Chlordiazepoxide. When dried, it contains not less than 99.0% of C₁₆H₁₄ClN₃O₂].

**Chlorhexidine hydrochloride** C₂₂H₃₀Cl₂N₁₀.2HCl [Same as the namesake monograph Chlorhexidine hydrochloride]

**Chlorinated lime** [Same as the namesake monograph]

**Chlorinated lime TS** Triturate 1 g of chlorinated lime with 9 mL of water, and filter. Prepare before use.

**Chlorine** Cl₂ A yellow-green gas, having a suffocating odor. It is heavier than air, and dissolves in water. Prepare from chlorinated lime with hydrochloric acid. Chlorine from a metal cylinder may be used.

**Chlorine TS** Use a saturated solution of chlorine in water. Preserve this solution in fully filled, light-resistant, glass-stoppered bottles, preferably in a cold place.

**Chloroacetic acid** C₂H₃ClO₂ [K 8899, Special class]

**p-Chloroaniline** See 4-chloroaniline

**4-Chloroaniline** H₂NC₆H₄Cl White crystals or crystalline powder. Freely soluble in ethanol (95) and in acetone, and soluble in hot water.

**Melting point** <2.60°: 70 – 72°C

**Residue on ignition** <2.44°: not more than 0.1% (1 g).

**4-Chlorobenzenediazonium TS** Dissolve 0.5 g of 4-chloroaniline in 1.5 mL of hydrochloric acid, and add water to make 100 mL. To 10 mL of this solution add 10 mL of sodium nitrite TS and 5 mL of acetone. Prepare before use.

**p-Chlorobenzene sulfonamide** See 4-chlorobenzene sulfonamide.

**4-Chlorobenzene sulfonamide** ClC₆H₄SO₂NH₂ White to pale yellow, odorless, crystalline powder. Dissolves in acetone.

**Purity** Related substances—Dissolve 0.60 g of 4-chlorobenzene sulfonamide in acetone to make exactly 300 mL, and perform the test with 5 μL of this solution as directed in the Purity (5) under Chlorproamidine: any spot other than the principal spot at the Rf value of about 0.5 does not appear.

**p-Chlorobenzoic acid** See 4-chlorobenzoic acid.

**4-Chlorobenzoic acid** C₆H₄COOH White crystals or powder. Sparingly soluble in ethanol (95), slightly soluble in chloroform, and practically insoluble in water.

**Melting point** <2.60°: 238 – 242°C

**Content** not less than 99.0%. Assay—Weigh accurately about 0.3 g of 4-chlorobenzoic acid, dissolve in 30 mL of neutralized ethanol, and titrate <2.50° with 0.1 mol/L sodium hydroxide VS (indicator: 2 drops of phenolphthalein TS). Each mL of 0.1 mol/L sodium hydroxide VS

\[= 15.66 \text{ mg of C}_6\text{H}_4\text{ClO}_2\]

**1-Chlorobutane** CH₃(CH₂)₂Cl Clear and colorless liquid, miscible with ethanol (95) and with diethyl ether, practically insoluble in water.

**Refractive index** <2.45° n₂₀°: 1.401 – 1.045

**Specific gravity** <2.56° d₂₀°: 0.884 – 0.890

**Boiling point** <2.57°: about 78°C

**Chlorobutanol** C₆H₅ClO [Same as the namesake monograph]

**1-Chloro-2,4-dinitrobenzene** C₆H₃(NO₂)₂Cl Light yellow crystals or crystalline powder.

**Melting point** <2.60°: 50 – 54°C.

Preserve in a light-resistant tight container.

**3′-Chloro-3′-deoxythymidine for liquid chromatography** C₁₀H₁₃N₃O₄Cl Occurs as a white powder.

**Purity**—Dissolve 10 mg of 3′-chloro-3′-deoxythymidine for liquid chromatography in the mobile phase to make 100 mL. Perform the test with 10 μL of this solution as directed in the Purity (3) under Zidovudine: a peak is not observed at the retention time for zidovudine.

**(2-Chloroethyl) diethylamine hydrochloride** C₆H₁₄ClN.HCl White powder.

**Content** not less than 95.0%. Assay—Weigh accurately about 0.2 g of (2-chloroethyl)diethylamine hydrochloride, previously dried at 45°C for 3 hours under reduced pressure, and dissolve in 15 mL of acetic acid (100). To this solution add 10 mL of a mixture of acetic acid (100) and mercury (II) acetate TS for nonaqueous titration (5:3), and titrate <2.50° with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS

\[= 17.21 \text{ mg of C}_6\text{H}_4\text{ClN.HCl}\]
Chloroform \( \text{CHCl}_3 \) [K 8322, Special class]

Chloroform, ethanol-free Mix 20 mL of chloroform with 20 mL of water, gently shake for 3 minutes, separate the chloroform layer, wash the layer again with two 20-mL portions of water, and filter it through dry filter paper. To the filtrate add 5 g of anhydrous sodium sulfate, shake for 5 minutes, allow the mixture to stand for 2 hours, and filter through dry filter paper. Prepare before use.

Chloroform for Karl Fischer method See Water Determination <2,48>.

Chlorogenic acid for thin-layer chromatography See (E)-chlorogenic acid for thin-layer chromatography.

(E)-Chlorogenic acid for thin-layer chromatography \( \text{C}_{16}\text{H}_{18}\text{O}_9 \) A white powder. Freely soluble in methanol and in ethanol (99.5), and sparingly soluble in water. Melting point: about 205°C (with decomposition).

Purity Related substances—Dissolve 1.0 mg of (E)-chlorogenic acid for thin-layer chromatography in 2 mL of methanol, and use this solution as the sample solution. Perform the test with this solution as directed under Thin-layer Chromatography <2,67>. Spot 10 \( \mu \)L of the sample solution on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of ethyl acetate, water and formic acid (6:1:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): no spot other than the principal spot at around \( R_f \) 0.5 appears.

\( p \)-Chlorophenol See 4-Chlorophenol.

4-Chlorophenol \( \text{ClC}_6\text{H}_4\text{OH} \) Colorless or pale red crystals or crystalline mass, having a characteristic odor. Very soluble in ethanol (95%), in chloroform, in diethyl ether and in glycerin, and sparingly soluble in water. Melting point: about 43°C.

Content: not less than 99.0%. Assay—Weigh accurately about 0.2 g of 4-chlorophenol, and dissolve in water to make 100 mL. Measure exactly 25 mL of this solution into an iodine flask, add exactly 20 mL of 0.05 mol/L bromine VS and then 5 mL of hydrochloric acid, stopper immediately, shake occasionally for 30 minutes, and allow to stand for 15 minutes. Add 5 mL of a solution of potassium iodide (1 in 5), stopper immediately, shake well, and titrate <2.50> with 0.1 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS). Perform a blank determination.

Each mL of 0.05 mol/L bromine VS = 3.214 mg of \( \text{C}_6\text{H}_5\text{ClO} \)

Preserve in tight, light-resistant containers.

(2-Chlorophenyl)-diphenylmethanol for thin-layer chromatography \( \text{C}_{24}\text{H}_{40}\text{O}_5 \) To 5 g of clotrimazole add 300 mg of 4-chlorophenol, and dissolve in water to make exactly 250 mL. Proceed with 10 \( \mu \)L of this solution as directed in the Purity (7) under Clotrimazole: any spot other than the principal spot does not appear.

Chloroplatinic acid See hydrogen hexachloroplatinate (IV) hexahydrate.

Chloroplatinic acid-potassium iodide TS See hydrogen hexachloroplatinate (IV)-potassium iodide TS.

Chloroplatinic acid TS See hydrogen hexachloroplatinate (IV) TS.

Chlorophenesin carbamate for assay \( \text{C}_{16}\text{H}_{19}\text{ClN}_2\cdot\text{C}_2\text{H}_4\text{O}_4 \) [Same as the monograph Chlorphenesin Carbamate. When dried, it contains not less than 99.0% of chlorphenesin carbamate (\( \text{C}_{16}\text{H}_{17}\text{ClN}_2\text{O}_4\)).]

Chlorpheniramine maleate \( \text{C}_{16}\text{H}_{19}\text{ClN}_2\cdot\text{C}_2\text{H}_4\text{O}_4 \) [Same as the namesake monograph]

Chlorpromazine hydrochloride for assay \( \text{C}_{17}\text{H}_{14}\text{ClN}_2\text{S} \cdot \text{HCl} \) [Same as the monograph Chlorpromazine Hydrochloride]

Chlorpropamide for assay \( \text{C}_{16}\text{H}_{17}\text{ClN}_2\text{O}_4 \) [Same as the monograph Chlorpropamide. When dried, it contains not less than 99.0% of chlorpropamide (\( \text{C}_{16}\text{H}_{17}\text{ClN}_2\text{O}_4\)).]

Cholesterol \( \text{C}_{19}\text{H}_{36}\text{OH} \) [Same as the namesake monograph]

Cholesterol benzoate \( \text{C}_{15}\text{H}_{20}\text{O}_2 \) White crystalline powder.

Melting point <2.60>: 145 – 152°C

Cholic acid for thin-layer chromatography \( \text{C}_{28}\text{H}_{40}\text{O}_6 \) White, crystals or crystalline powder. Soluble in acetic acid (100), sparingly soluble in acetone and in ethanol (95), and very slightly soluble in water. Melting point: about 198°C.

Purity Related substances—Dissolve 25 mg in acetone to make exactly 250 mL. Proceed with 10 \( \mu \)L of this solution as directed in the Purity (7) under Ursodeoxycholic Acid: any spot other than the principal spot, having \( R_f \) about 0.1, does not appear.

Content: not less than 98.0%. Assay—Weigh accurately about 0.5 g, previously dried at 80°C for 4 hours (in vacuum, phosphorous (V) oxide), dissolve in 40 mL of neutralized ethanol and 20 mL of water, add 2 drops of phenolphthalein TS, and titrate with 0.1 mol/L sodium hydroxide VS until immediately before the end-point has been reached. Then add 100 mL of freshly boiled and cooled water, and continue the titration <2.50>. Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 40.86 mg of \( \text{C}_{19}\text{H}_{36}\text{O}_6 \)

Choline chloride \( \left(\text{CH}_3\right)_3\text{NCH}_2\text{CH}_2\text{OH}\)Cl White crystalline powder.

Melting point <2.60>: 303 – 305°C (decomposition).

Water <2.48>: less than 0.1%.
Chromic acid-sulfuric acid TS
Saturate chromium (VI) trioxide in sulfuric acid.

Chromium trioxide See chromium (VI) trioxide.

Chromium trioxide TS See chromium (VI) trioxide TS.

Chromium (VI) trioxide CrO₃
A dark red-purple thin needle-shaped or inner prism-like crystals, or light masses.

Identification—To 5 mL of a solution (1 in 50) add 0.2 mL of lead (II) acetate TS: yellow precipitates appear which does not dissolve on the addition of acetic acid.

Chromium (VI) trioxide TS
Dissolve 3 g of chromium (VI) trioxide in water to make 100 mL.

Chromogenic synthetic substrate
Equal amount mixture of N-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginyl-p-nitroanilid hydrochloride and N-benzoyl-L-isoleucyl-p-methoxy glutamyl-glycyl-L-arginyl-p-nitroanilid hydrochloride. White or pale yellow masses or powder. It is slightly soluble in water.

Identification—Perform the test with the solution (1 in 30,000) as directed under Untraviolet-visible Spectrophotometry 2.24: the absorption maximum at about 316 nm is observed.

Purity
Free 4-nitroaniline: not more than 0.5%.

Loss on drying
<2.40: not more than 5% (0.2 g, reduced pressure (0.3 kPa), calcium chloride, between 30 and 40°C, 18 hours).

Content:
not less than 95% and not more than 105% of the label.

Chromophore TS for teceleukin
Mix 0.1 mL of diluted hydrogen peroxide (30) (1 in 20) with 10 mL of 0.2 mol/L citric acid buffer, pH 3.8, containing 0.2 mmol/L 3,3'-5,5'-tetramethylbenzidine dihydrochloride dehydrate, and use immediately.

Cibenzoline succinate for assay C₁₈H₁₈N₂C₄H₆O₄
Same as the monograph Cibenzoline Succinate. When dried, it contains not less than 99.0% of cibenzoline succinate (C₁₈H₁₈N₂C₄H₆O₄) and meets the following requirements.

Purity
Related substances—Dissolve 0.10 g of cibenzoline succinate in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add methanol to make exactly 100 mL. To exactly 1 mL of this solution add methanol to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography 2.01. Spot 10 μL of each sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of ethyl acetate, methanol and ammonia solution (28) (20:3:2) to a distance of about 10 cm, air-dry the plate, and dry at 80°C for 30 minutes. After cooling, examine under ultraviolet light (main wavelength: 254 nm): the spot other than the principal spot obtained with the sample solution is not more intense than the spot with the standard solution. On standing the plate for 30 minutes in the tank saturated with iodine vapor, the spot other than the principal spot obtained with the sample solution is not more intense than the spot with the standard solution.

Cilastatin ammonium for assay C₁₆H₂₉N₃O₅S: 375.48
A white crystalline powder.

Water
<2.40: not more than 0.5% (0.5 g, volumetric titration, direct titration).

Residue on ignition
<2.40: not more than 0.5% (1 g).

Purity
Related substances—Dissolve 40 mg of the substance to be examined in 25 mL of water, and use this as the sample solution. Pipet 3 mL of the sample solution, add water to make exactly 100 mL, and use this as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography 2.01 according to the following conditions, and determine the each peak area by the automatic integration method. Separately, perform the test with 20 μL of water in the same manner to correct any variance of the peak area caused the variation of the baseline: the total area of the peaks other than cilastatin is not larger than 1/6 times the peak area of cilastatin from the standard solution.

Operating conditions
Detector: An ultraviolet absorption photometer (wavelength: 210 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 30°C.

Mobile phase A: A mixture of dilute phosphoric acid (1 in 1000) and acetonitrile (7:3).

Mobile phase B: Diluted phosphoric acid (1 in 1000).

Flowing of the mobile phase: Control the gradient by mixing the mobile phases A and B as directed in the following table.

<table>

Flow rate: 2.0 mL per minute.

Time span of measurement: 40 minutes.

System suitability
Test for required detectability: To exactly 1 mL of the standard solution add water to make exactly 30 mL. Confirm that the peak area of cilastatin obtained with 20 μL of this solution is equivalent to 2.3 to 4.5% of that with 20 μL of the standard solution.

System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions: the retention time of cilastatin is about 20 minutes, and the number of theoretical plates and the symmetry factor of the peak of cilastatin are not less than 10,000 and not more than 2.5, respectively.

System repeatability: When the test is repeated 3 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of cilastatin is not more than 3.0%.

Residual solvent—Weigh accurately about 1 g, dissolve in water to make exactly 100 mL, and use this as the sample solution. Separately, weigh accurately about 0.10 g of ethanol (99.5), add water to make exactly 100 mL, and use this as the standard solution. Perform the test with exactly 1 μL each of the sample solution and standard solution as directed under
Gas Chromatography 2.02 according to the following conditions. Determine the peak areas, $A_T$ and $A_S$, of ethanol by the automatic integration method, and calculate the amount of ethanol ($C_2H_5OH$): not more than 0.5%.

$$\text{Amount} \times 100 \times M_1 \times M_S = M_2$$

$M_5$: Amount (mg) of ethanol (99.5)
$M_1$: Amount (mg) of the sample

Operating conditions

**Detector:** A hydrogen flame-ionization detector.

**Column:** A fused silica column 0.5 mm in inside diameter and 30 m in length, coated the inside with 5% diphenyl-95% dimethylpolysiloxane for gas chromatography in thickness of 5 μm.

**Column temperature:** Inject the sample at a constant temperature of about 50°C, keep on for 150 seconds, then raise to 70°C at the rate of 8°C per minute, and keep this for 30 seconds.

**Carrier gas:** Helium.

**Flow rate:** Adjust so that the retention time of ethanol is about 1 minute.

**Sprint ratio:** 5:1

**System suitability**

Test for required detectability: To exactly 1 mL of the standard solution add water to make exactly 10 mL, and designate this the solution for system suitability test. To exactly 1 mL of the solution for system suitability test add water to make exactly 10 mL. Confirm that the peak area of ethanol obtained with 1 μL of this solution is equivalent to 7 to 13% of that with 1 μL of the solution for system suitability test.

**System performance:** When the procedure is run with 1 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of ethanol are not less than 1500 and not more than 1500 and not more than 3.0, respectively.

**System repeatability:** When determine the peak area of methanol by repeating 6 times with 1 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area is not more than 2.0%.

**Content:** not less than 99.0% of cilastatin ammonium ($C_{16}H_{29}N_3O_5S$), calculated on the anhydrous basis and corrected on the amount of ethanol. Assay—Weigh accurately about 0.5 g, dissolve in 30 mL of methanol, and add 5 mL of water. Adjust to pH 3.0 with 0.1 mol/L hydrochloric acid TS, and titrate 2.50 with 0.1 mol/L perchloric acid VS (indicator: 3 drops of crystal violet). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L perchloric acid VS

\[ = 14.72 \text{ mg of } C_{16}H_{29}N_3O_5 \]

**Cinchonidine** $C_{19}H_{22}N_2O$ White crystals or crystalline powder. Soluble in ethanol (95), in methanol and in chloroform, sparingly soluble in diethyl ether, and practically insoluble in water. A solution of cinchonidine in ethanol (95) (1 in 100) is levorotatory. Melting point: about 207°C

**Content:** not less than 98.0%. Assay—Weigh accurately about 0.3 g of cinchonidine, dissolve in 20 mL of acetic acid (100), add 80 mL of acetic anhydride, and titrate 2.50 with 0.1 mol/L perchloric acid VS (indicator: 3 drops of crystal violet). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L perchloric acid VS

\[ = 14.72 \text{ mg of } C_{19}H_{22}N_2O \]

**Cinchonine** $C_{19}H_{22}N_2O$ White crystals or powder.

**Identification:** Dissolve 1 g in 20 mL of dilute hydrochloric acid (1 in 4), and add 2 mL of potassium hexacyanoferrate (II) TS: yellow precipitates appear, which are dissolved by heating, and crystals are formed after allowing to cool.

**Purity** Cinchonidine and quinine—To 1 g add 30 mL of water, add dilute hydrochloric acid (2 in 3) dropwise until the substance to be tested dissolves, and neutralize with ammonia TS. To this solution add 10 mL of a solution of sodium tartrate dihydrate (1 in 2), boil, and allow to stand for 1 hour: no precipitates appear.

**Content:** not less than 98.0%. Assay—Weigh accurately about 0.3 g, dissolve in 50 mL of acetic acid (100), and titrate 2.50 with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS

\[ = 14.72 \text{ mg of } C_{19}H_{22}N_2O \]

**Cineol for assay** $C_{10}H_{18}O$ Clear and colorless liquid, having a characteristic aroma.

**Refractive index** 2.457 – 2.459

**Specific gravity** 2.50

**Purity** (1) Related substances (i)—Dissolve 0.20 g of cineol for assay in 10 mL of hexane and use this solution as the sample solution. Perform the test with the sample solution as directed under Thin-layer Chromatography 2.02. Spot 5 μL of the sample solution on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of hexane and ethyl acetate (9:1) to a distance of about 10 cm, and air-dry. Spray evenly 4-methoxybenzaldehyde-sulfuric acid TS, and heat at 105°C for 5 minutes: any spot other than the principal spot does not appear.

(2) Related substances (ii)—Dissolve 0.10 g of cineol for assay in 25 mL of hexane and use this solution as the sample solution. Perform the test with 2 μL of the sample solution as directed under Gas Chromatography 2.02 according to the following conditions. Measure each peak area by the automatic integration method and calculate the amount of cineol by the area percentage method: it is not less than 99.0%.

**Operating conditions**

Proceed the operating conditions in the Assay under Eucalyptus Oil except detection sensitivity and time span of measurement.

**Detection sensitivity:** Measure 1 mL of the sample solution and add hexane to make 100 mL. Adjust the detection sen-
sitivity so that the peak height of cineol obtained from 2 μL of this solution is 40% to 60% of the full scale.

Time span of measurement: About 3 times as long as the retention time of cineol beginning after the solvent peak.

**Cinnamaldehyde for thin-layer chromatography** See (E)-cinnamaldehyde for thin-layer chromatography.

**(E)-Cinnamaldehyde for thin-layer chromatography**

C_{9}H_{8}O \ A colorless or light yellow liquid, having a characteristic aromatic odor. Very soluble in methanol and in ethanol (99.5), and practically insoluble in water.

Absorbance \ <2.24 \ \varepsilon_{273}^{1} (285 nm): \ 1679 – 1943 (5 mg, methanol, 2000 mL).

Purity Related substances—Dissolve 10 mg of (E)-cinnamaldehyde for thin-layer chromatography in 2 mL of methanol. Perform the test with 1 μL of this solution as directed in the Identification (3) under Kakkonto Extract: no spot other than the principal spot (Rf value is about 0.4) appears.

**Cinnamic acid** C_{9}H_{8}O_{2} White crystalline powder, having a characteristic odor.

Melting point \ <2.60: \ 132 – 135°C

**(E)-Cinnamic acid for assay** (E)-Cinnamic acid for thin-layer chromatography. It meets the following requirements.

Purity Related substances—Conduct this procedure without exposure to light, using light-resistant vessels. Dissolve 10 mg in 50 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography \ <2.0: \ \varepsilon_{295}^{1} \ \text{according to the following conditions, and determine each peak area by the automatic integration method and calculate the amount of cinobufagin is about 7 minutes.} \ \text{the method: the total area of the peaks other than (E)-cinnamic acid and the solvent is not larger than the peak area of (E)-cinnamic acid obtained with the standard solution.}

Operating conditions

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay (1) under Ryokejutsukanto Extract.

Time span of measurement: About 6 times as long as the retention time of (E)-cinnamic acid.

System suitability

Test for required detectability: To exactly measured 1 mL of the standard solution add the mobile phase to make exactly 20 mL. Confirm that the peak area of (E)-cinnamic acid obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.

System performance, and system repeatability: Proceed as directed in the system suitability in the Assay (1) under Ryokejutsukanto Extract.

**(E)-Cinnamic acid for thin-layer chromatography**

C_{9}H_{8}O_{2} White crystals or crystalline powder, having a characteristic aromatic odor. Freely soluble in methanol and in ethanol (99.5), and practically insoluble in water.

Melting point \ <2.60: \ 132 – 136°C

Absorbance \ <2.24 \ \varepsilon_{273}^{1} (273 nm): \ 1307 – 1547 (5 mg dried with silica gel for 24 hours, methanol, 1000 mL).

Purity Related substances—Conduct this procedure without exposure to light, using light-resistant vessels. Dissolve 10 mg in 5 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Proceed the test with 10 μL each of the sample solution and standard solution as directed in the Identification (1) under Ryokejutsukanto Extract: the spot other than the principal spot of around Rf 0.5 is not more intense than the spot obtained with the standard solution.

**(E)-Cinnamic acid for component determination** See (E)-cinnamic acid for assay.

**Cinobufagin for assay** C_{22}H_{34}O_{5}xH_{2}O White crystalline odorless powder.

Absorbance \ <2.24 \ \varepsilon_{273}^{1} \text{(295 nm):} \ 125 – 127 (10 mg, methanol, 250 mL). Use the sample dried in a desiccator (silica gel) for 24 hours for the test.

Purity Related substances—Proceed with 40 mg of cinobufagin for assay as directed in the Purity under bufalin for component determination.

Content: Not less than 98.0%. Assay—Weigh accurately about 10 mg of cinobufagin for assay, previously dried in a desiccator (silica gel) for 24 hours, dissolve in methanol to make exactly 10 mL, and use this solution as the sample solution. Perform the test with 20 μL of the sample solution as directed under Liquid Chromatography \ <2.0: \ \varepsilon_{295}^{1} \ \text{according to the following conditions. Measure each peak area by the automatic integration method and calculate the amount of cinobufagin by the area percentage method.}

Operating conditions

Detector: Ultraviolet absorption photometer (wavelength: 295 nm).

Column: A stainless steel column 4 to 6 mm in inside diameter and 15 to 30 cm in length, packed with octadecyl-silanized silica gel for liquid chromatography (5 to 10 μm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of water and acetonitrile (1:1).

Flow rate: Adjust the flow rate so that the retention time of cinobufagin is about 7 minutes.

Selection of column: Dissolve 10 mg each of bufalin for assay, cinobufagin for assay and resibufogenin for assay in methanol to make 200 mL. Proceed with 20 μL of this solution under the above operating conditions. Use a column giving elution of bufalin, cinobufagin and resibufogenin in this order, and clearly dividing each peak.

Detection sensitivity: Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution (1). Pipet 1 mL of the standard solution (1), add methanol to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of cinobufagin obtained from 20 μL of the standard solution (2) can be measured by the automatic integration method, and the peak height of cinobufagin from 20 μL of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About twice as long as the retention time of cinobufagin beginning after the solvent peak.

**Cinobufagin for component determination** See cinobufagin for assay.

**Cinnoxacin for assay** C_{13}H_{10}N_{2}O_{5} [Same as the mono-
graph Cinoxacin. When dried, it contains not less than 99.0% of cinoxacin (C₁₂H₁₀N₂O₅).

Cisplatin Cl₂H₂N₂Pt [Same as the namesake monograph]

Citic acid See citric acid monohydrate.

Citic acid-acetic acid TS To 1 g of citric acid monohydrate add 90 mL of acetic anhydride and 10 mL of acetic acid (100), and dissolve under shaking.

Citic acid-acetic anhydride TS To 1 g of citric acid monohydrate add 50 mL of acetic anhydride, and dissolve by heating. Prepare before use.

Citic acid monohydrate C₆H₈O₇·H₂O [K 8283, or same as the monograph Citric Acid Hydrate]

Citic acid-phosphate-acetonitrile TS Dissolve 2.1 g of citric acid monohydrate, 13.4 g of dipotassium hydrogen phosphate and 3.1 g of potassium dihydrogen phosphate in 1000 mL of a mixture of water and acetonitrile (3:1).

0.01 mol/L. Citric acid TS Dissolve 2.1 g of citric acid monohydrate in water to make 1000 mL.

1 mol/L. Citric acid TS for buffer solution Dissolve 210.14 g of citric acid monohydrate in water to make 1000 mL.

Clofibrate C₁₅H₁₃ClO₃ [Same as the namesake monograph]

Clozazolam C₁₇H₁₄Cl₂N₂O₂ [Same as the namesake monograph]

Cobalt (II) chloride-ethanol TS Dissolve 0.5 g of cobalt (II) chloride hexahydrate, previously dried at 105°C for 2 hours, in ethanol (99.5) to make 100 mL.

Cobalt (II) chloride hexahydrate CoCl₂·6H₂O [K 8129, Special class]

Cobalt (II) chloride TS Dissolve 2 g of cobalt (II) chloride hexahydrate in 1 mL of hydrochloric acid and water to make 100 mL (0.08 mol/L).

Cobalt (II) nitrate hexahydrate Co(NO₃)₂·6H₂O [K 8552, Special class]

Cobaltous chloride See cobalt (II) chloride hexahydrate.

Cobaltous nitrate See cobalt (II) nitrate hexahydrate.

Codeine phosphate for assay See codeine phosphate hydrate for assay.

Codeine phosphate hydrate for assay C₁₅H₁₂NO₃·H₃PO₄·½H₂O [Same as the monograph Codeine Phosphate Hydrate. It contains not less than 99.0% of codeine phosphate (C₁₅H₁₂NO₃·H₃PO₄), calculated on the anhydrous basis.]

Collodion Clear, colorless, viscous liquid, having a diethyl ether-like odor.

\[ \text{pH} < 2.5; 5.0 - 8.0 \]

Stir 5 g of collodion while warming, add 10 mL of water gradually, and dry at 110°C after evaporating to dryness: mass of the residue is 0.250–0.275 g.

Concentrated chromotropic acid TS See chromotropic acid, concentrated.

Concentrated diazobenzenesulfonic acid TS See diazobenzenesulfonic acid TS, concentrated.

Congo red C₁₂H₁₂N₂Na₂O₆S₂ [K 8532, Special class]

Congo red TS Dissolve 0.5 g of congo red in 100 mL of a mixture of ethanol (95) and water (1:9).

Control anti-interleukin-2 antiserum TS Anti-interleukin-2 antiserum is diluted with culture media for celmoleu-kin, so that the diluted antiserum solution neutralizes the same volume of about 800 unit/mL solution of Celmoleukin (Genetical Recombination).

Coomassie brilliant blue G-250 C₁₅H₁₈N₂O₅S [K 8552, Special class] A deep violet powder. A solution in ethanol (99.5) (1 in 100,000) exhibits an absorption maxima at a wavelength of 608 nm.

Content: not less than 50%.

Coomassie staining TS Dissolve 125 mg of Coomassie brilliant blue R-250 in 100 mL of a mixture of water, methanol and acetic acid (100) (5:4:1), and filter.

Copper Cu [K 8660, Special class]

Copper (II) acetate monohydrate Cu(CH₃COO)₂·H₂O Blue-green crystals or crystalline powder.

Identification—(1) Dissolve 1 g of copper (II) acetate monohydrate in 10 mL of diluted sulfuric acid (1 in 2), and heat: the odor of acetic acid is perceptible.

(2) Dissolve 0.1 g of copper (II) acetate monohydrate in 20 mL of water, and add 3 mL of ammonia solution (28): a dark blue color is developed.

Copper (II) acetate TS, strong Dissolve 13.3 g of copper (II) acetate monohydrate in a mixture of 195 mL of water and 5 mL of acetic acid.

Copper (II) chloride-acetone TS Dissolve 0.3 g of copper (II) chloride dihydrate in acetone to make 10 mL.

Copper (II) chloride dihydrate CuCl₂·2H₂O [K 8145, Special class]

Copper (II) disodium ethylenediamine tetraacetate tetrahydrate C₁₅₀H₁₂₀Cl₂N₂O₄·4H₂O A blue powder.

\[ \text{pH} < 2.5; 7.0 - 9.0 \]

Purity Clarity and color of solution—Add 0.10 g of copper (II) disodium ethylenediamine tetraacetate tetrahydrate to 10 mL of freshly boiled and cooled water: the solution is blue in color and clear.

Content: not less than 98.0%. Assay—Weigh accurately about 0.45 g of copper (II) disodium ethylenediamine tetraacetate tetrahydrate, and add water to make exactly 100 mL. Pipet 10 mL of this solution, adjust the pH of the mixture to about 1.5 by adding 100 mL of water and dilute nitric acid, then add 5 mL of a solution of 1,10-phenanthroline mono-
hydrate in methanol (1 in 20), and titrate $<2.50$ with 0.01 mol/L bismuth nitrate VS until the color of the solution changes from yellow to red (indicator: 2 drops of xylol orange TS).

Each mL of 0.01 mol/L bismuth nitrate VS = 4.698 mg of Cu$_{2}$H$_3$CuN$_2$Na$_2$O$_8$.4H$_2$O

Copper (II) hydroxide Cu(OH)$_2$. Light blue powder. Practically insoluble in water.

*Content*: not less than 95.0% as Cu(OH)$_2$. Assay—Weigh accurately about 0.6 g of Copper (II) hydroxide, and dissolve in 3 mL of hydrochloric acid and water to make exactly 500 mL. Pipet 25 mL of this solution, add 75 mL of water, 10 mL of a solution of ammonium chloride (3 in 50), 3 mL of diluted ammonia solution (28) (1 in 10) and 0.05 g of murexide-sodium chloride indicator, and titrate $<2.50$ with 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate VS until the color of the liquid is changed from yellow-green to red-purple.

Each mL of 0.01 mol/L disodium dihydrogen ethylenediamine tetraacetate VS = 0.9756 mg of Cu(OH)$_2$.

Copper (II) sulfate CuSO$_4$ [K 8984, First class]

Copper (II) sulfate pentahydrate CuSO$_4$.5H$_2$O [K 8983, Special class]

Copper (II) sulfate-pyridine TS Dissolve 4 g of copper (II) sulfate pentahydrate in 90 mL of water, then add 30 mL of pyridine. Prepare before use.

Copper (II) sulfate TS, alkaline Dissolve 150 g of potassium bicarbonate, 101.4 g of potassium carbonate and 6.93 g of copper (II) sulfate pentahydrate in water to make 1000 mL.

Copper (II) sulfate TS Dissolve 12.5 g of copper (II) sulfate pentahydrate in water to make 100 mL (0.5 mol/L).

Copper (standard reagent) Cu [K 8005, Standard reagent for qualitative analysis]

Coptisine chloride for thin-layer chromatography C$_{19}$H$_{14}$NO$_{4}$Cl Orange-red, crystals or crystalline powder. Slightly soluble in methanol, and very slightly soluble in water and in ethanol (99.5). Melting point: about 260°C (with decomposition).

Identification Determine the absorption spectrum of a solution (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry $<2.24>$. It exhibits maxima between 237 nm and 241 nm, between 264 nm and 268 nm, between 354 nm and 358 nm, and between 452 nm and 462 nm.

Purity Related substances—Dissolve 1 mg in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography $<2.05>$. Spot 1 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of methanol, ammonium acetate solution (3 in 10) and acetic acid (100) (20:1:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): the spot other than the principal spot (Rf value is about 0.4) obtained from the sample solution is not more intense than the spot from the standard solution.

Corn oil [Same as the namesake monograph]

Cortisone acetate C$_{25}$H$_{35}$O$_{6}$ [Same as the namesake monograph]

Cottonseed oil A refined, nonvolatile fatty oil obtained from the seed of plants of Gossypium hirsutum Linné (Gossypium) or of other similar species. A pale yellow, odorless, oily liquid. Miscible with diethyl ether, and with hexane. Slightly soluble in ethanol (95).

Refractive index $<2.45> n^20_{D}$: 1.472 – 1.474

Specific gravity $<2.50> d^25_{20}$: 0.915 – 0.921

Acid value $<1.13>$: not more than 0.5.

Saponification value $<1.13>$: 190 – 198

Iodine value $<1.13>$: 103 – 116

Cresol CH$_3$C$_6$H$_4$(OH) [Same as the namesake monograph]

m-Cresol CH$_3$C$_6$H$_4$(OH) [K 8305, Special class]

m-Cresol purple See metacresol purple.

m-Cresol purple TS See metacresol purple TS.

p-Cresol CH$_3$OH [K 8306, Special class]

Cresol red C$_{22}$H$_{21}$O$_{6}$S [K 8308, Special class]

Cresol red TS Dissolve 0.1 g of cresol red in 100 mL of ethanol (95), and filter if necessary.

Crystalline trypsin To trypsin obtained from bovine pancreas gland add an appropriate amount of trichloroacetic acid to precipitate the trypsin, and recrystallize in ethanol (95). White to yellowish white crystals or powder. It is odorless. Freely soluble in water and in sodium tetraborate-calcium chloride buffer solution, pH 8.0.

*Content*: not less than 45 FIP Units of trypsin per mg. Assay—(i) Sample solution: Weigh accurately an appropriate amount of crystallized trypsin according to the labeled Units, dissolve in 0.001 mol/L hydrochloric acid TS to prepare a solution containing 50 FIP Units per mL, and use this solution as the sample solution. Prepare before use, and preserve in ice. (ii) Apparatus: Use a glass bottle as a reaction reservoir 20 mm in inside diameter and 50 mm in height, equipped with a rubber stopper for attachment to a glass/silver-silver chloride electrode for pH determination, nitrogen-induction tube and an exhaust port. Fix the reaction reservoir in a thermostat, and keep the temperature at 25 ± 0.1°C by means of a precise thermostimulator. (iii) Procedure: Pipet 1.0 mL of Na$_2$-benzoyl-L-arginine ethyl ester TS, transfer to the reaction reservoir, and add 9.0 mL of sodium tetraborate-calcium chloride buffer solution, pH 8.0. Allow to stand in the thermostat for 10 minutes to make the temperature of the contents reach to 25 ± 0.1°C, adjust the pH of the solution to 8.00 by adding dropwise 0.1 mol/L sodium hydroxide VS while stirring and passing a current of nitrogen, add exactly 0.05 mL of the sample solution previously allowed to stand at 25 ± 0.1°C, then immediately add dropwise 0.1 mol/L sodium hydroxide VS by a 50 μL-micropipet (minimum graduation of 1 μL) while stirring to keep the reaction solution at pH 8.00, and read the amount of 0.1 mol/L sodium hydroxide VS consumed and the reaction time when the pH reached 8.00. Continue this procedure up to 8 minutes. Separately, transfer 10 mL of sodium
tetraborate-calcium chloride buffer solution, pH 8.0, and perform a blank determination in the same manner. (iv) Calculation: Plot the amount of consumption (μL) of 0.1 mol/L sodium hydroxide VS against the reaction time (minutes), select linear reaction times, \( t_1 \) and \( t_2 \), designate the corresponding consumption amount of 0.1 mol/L sodium hydroxide VS as \( v_1 \) and \( v_2 \), respectively, and designate \( f \) of sodium hydroxide consumed per minute as \( D \) (FIP Unit).

\[
D \text{ (μmol NaOH/min)} = \frac{v_2 - v_1}{t_2 - t_1} \times f \times \frac{1}{10}
\]

\( f \): Factor of 0.1 mol/L sodium hydroxide VS

FIP Units per mg of crystallized trypsin to be tested

\[
= \frac{(D_1 - D_0) \times T}{L \times M}
\]

\( D_1 \): μmol of sodium hydroxide consumed in 1 minute when the sample solution is used

\( D_0 \): μmol of sodium hydroxide consumed in 1 minute when the solution for blank determination is used

\( M \): Amount (mg) of crystallized trypsin sampled

\( L \): Amount (mL) of the sample solution put in the reaction reservoir

\( T \): Total volume (mL) of the sample solution prepared by dissolving in 0.001 mol/L hydrochloric acid TS

One FIP Unit is an amount of enzyme which decomposes 1 μmol of N-α-benzoyl-L-arginine ethyl ester per minute under the conditions described in the Assay.

Storage—Preserve in a cold place.

Crystalline trypsin for ulinastatin assay A proteolytic enzyme prepared from bovine pancreas. White to light yellow crystalline powder. Odorless. Sparingly soluble in water, and dissolves in 0.001 mol/L hydrochloric acid TS.

Content: not less than 3200 trypsin Units per mg. Assay—(i) Sample solution: Weigh accurately about 20 mg of crystalline trypsin for ulinastatin assay, and dissolve in 0.001 mol/L hydrochloric acid TS so that each mL of the solution contains about 3000 trypsin Units. Dilute this solution with 0.001 mol/L hydrochloric acid TS so that each mL of the solution contains about 40 trypsin Units, and use this solution as the sample solution. (ii) Diluent: Dissolve 4.54 g of potassium dihydrogen phosphate in water to make exactly 500 mL (Solution I). Dissolve 4.73 g of anhydrous disodium hydrogen phosphate in water to make exactly 500 mL (Solution II). To 80 mL of Solution II add a suitable amount of Solution I to adjust to pH 7.6. (iii) Substrate solution: Dissolve 85.7 mg of N-α-benzoyl-L-arginine ethyl ester hydrochloride in water to make exactly 100 mL, and use this solution as the substrate stock solution. Pipet 10 mL of the stock solution, add the diluent to make exactly 100 mL, and use this solution as the substrate solution. The absorbance of the substrate solution determined at 253 nm as directed under Ultra-violet-visible Spectrophotometry \( <2.24 > \) using water as the blank solution. Determine the difference of the absorbance change per minute, \( A \), when the difference has been constant for at least 3 minutes. (v) Calculation: Trypsin Units per mg is obtained by use of the following equation. One trypsin Unit is an amount of the enzyme which gives 0.003 change in absorbance per minute under the conditions described above.

\[
\text{Trypsin Units per mg} = \frac{A}{0.003 \times M}
\]

\( M \): Amount (mg) of the substance to be assayed in 0.2 mL of the sample solution

Storage—Preserve in a cold place.

Crystal violet C\(_2\)H\(_3\)N\(_3\)O\(_2\) [K 8289, Special class]

Crystal violet TS Dissolve 0.1 g of crystal violet 10 mL of acetic acid (100).

Culture medium for assay of teceleukin Add 100 mL of fetal calf serum to 1000 mL of medium for float culture. Store at 4°C.

Culture medium for celmoleukin Take a specified amount of RPMI-1640 powdered medium that contains glutamate but does not contain sodium hydrogen carbonate, add water to dissolve, and add N-2-hydroxyethylpiperidine-N-2-ethansulfonic acid as a buffering agent to a concentration of 0.025 mol/L. To 1000 mL of this solution add 0.1 g (potency) of streptomycin sulfate, 100,000 units of potassium benzylpenicillin, and 2 g of sodium hydrogen carbonate, adjust the pH to 7.1 to 7.2 with sodium hydroxide TS, and then sterilize by filtration. To this solution add fetal calf serum heated at 56°C for 30 minutes to 20 vol%.

Cu-PAN Prepare by mixing 1 g of 1-(2-pyridylazo)-2-naphthol (free acid) with 11.1 g of copper (II) disodium ethylenediamine tetraacetate tetrahydrate.

A grayish orange-yellow, grayish red-brown or light grayish purple powder.

Absorbance—Dissolve 0.50 g of Cu-PAN in diluted 1,4-dioxane (1 in 2) to make exactly 50 mL. Pipet 1 mL of this solution, add methanol to make exactly 100 mL. Read the absorbance of this solution at 470 nm as directed under Ultra-violet-visible Spectrophotometry \( <2.24 > \), using water as the blank solution: the absorbance is not less than 0.48.

Purity Clarity and color of solution—Dissolve 0.50 g of Cu-PAN in 50 mL of diluted 1,4-dioxane (1 in 2); the solution is clear and yellow-brown.

Cu-PAN TS Dissolve 1 g of Cu-PAN in 100 mL of diluted 1,4-dioxane (1 in 2).

Cupferron C\(_6\)H\(_4\)N\(_2\)O\(_2\) [K 8289, Special class]

Cupferron TS Dissolve 6 g of cupferron in water to make 100 mL. Prepare before use.

Cupric acetate See copper (II) acetate monohydrate.

Cupric acetate TS, strong See copper (II) acetate monohydrate TS, strong.

Cupric carbonate See cupric carbonate monohydrate.

Cupric carbonate monohydrate Cu\(_2\)CO\(_3\)·Cu(OH)\(_2\)·H\(_2\)O A blue to blue-green powder. It is insoluble in water, and dissolves annoyingly in dilute acid. It dissolves in ammonia TS and shows a deep blue color.

Purity (1) Chloride \(<1.0\%\>): not more than 0.036%.

...
(2) Sulfate \( <1.14\% \): not more than 0.120%.

(3) Iron—Dissolve 5.0 g of cupric carbonate monohydrate in excess ammonia TS and filter. Wash the residue with ammonia TS, dissolve in dilute hydrochloric acid, add excess ammonia TS and filter. Wash the residue with ammonia TS, and dry to constant mass: the residue is not more than 10 mg.

Cupric chloride See copper (II) chloride dihydrate.

Cupric chloride-acetone TS See copper (II) chloride-acetone TS.

Cupric sulfate See copper (II) sulfate pentahydrate.

Cupric sulfate, anhydrous See copper (II) sulfate (anhydrous).

Cupric sulfate-pyridine TS See copper (II) sulfate-pyridine TS.

Cupric sulfate solution, alkaline See copper (II) sulfate solution, alkaline.

Cupric sulfate TS See copper (II) sulfate TS.

1 mol/L Cupriethylenediamine TS Put 100 g of copper (II) hydroxide in a 1-L thick-walled bottle marked a 500-mL line, and add water to make 500 mL. Connect the bottle with a liquid introducing funnel, a introducing glass tube and a gas removing glass tube. Adjust so that the lower end of the bottom of the bottle. Introduce the nitrogen for about 3 hours to replace the inside gas by adjusting the pressure (about 14 kPa) to a mild bubbling. Then add gradually 160 mL of ethylenediamine TS through the funnel while introducing the nitrogen and cooling the bottle with the running water, and replace the funnel with a glass rod to close tightly. After introducing the nitrogen for further 10 minutes, replace the gas removing tube with a glass rod to close tightly. Keep the inside pressure with the nitrogen to about 14 kPa. After allowing the bottle to stand for about 16 hours while occasional shaking, filter the content if necessary using a glass-filter under reducing pressure, and reserve under nitrogen atmosphere. The concentration of copper (II) ion of this solution is about 1.3 mol/L. Determine the concentration of ethylenediamine of this solution using a titration method with 0.1 mol/L hydrochloric acid VS (pH Determination \( <2.5\% \)).

\[
X = \frac{N_1 \cdot a}{V_1}
\]

\( X \): Concentration of ethylenediamine (mol/L)
\( a \): Volume of 0.1 mol/L hydrochloric acid VS consumed for the titration (mL)
\( N_1 \): Concentration of 0.1 mol/L hydrochloric acid VS (mol/L)

(2) Copper (II) ion—Pipet 2 mL (\( V_2 \)) of the solution to be assayed, add 20 mL of water, about 3 g of potassium iodide and 50 mL of 2 mol/L sulfuric acid TS, shake for 5 minutes, and titrate \( <2.50\% \) the liberated iodine with 0.1 mol/L sodium thiosulfate VS. When the solution turns light yellow at near the end point add 3 mL of starch TS and 10 mL of a solution of ammonium thiocyanate (2 in 10), and then titrate until the blue color disappears.

\[
Y = \frac{N_2 \cdot b}{V_2}
\]

\( Y \): Concentration of copper (II) ion (mol/L)
\( b \): Volume of 0.1 mol/L sodium thiosulfate VS consumed for the titration (mL)
\( N_2 \): Concentration of 0.1 mol/L sodium thiosulfate VS (mol/L)

Curcumin \( C_{21}H_{20}O_6 \) A reddish yellow crystalline powder.

Melting point \( <2.60\% \): 180 – 183°C. Preserve in a light-resistant tight container.

Curcumin TS Dissolve 0.125 g of curcumin in acetic acid (100) to make 100 mL. Prepare this solution as the sample solution.

Curcumin for assay \( C_{21}H_{20}O_6 \) Yellow to orange crystalline powder. Slightly soluble in methanol, very slightly soluble in ethanol (99.5), and practically insoluble in water.

Absorbance \( <2.24\% \) \( E_{1\%}^{1cm} \) (422 nm): 1460 – 1700 (dried for 24 hours in a desiccator (in vacuum, silica gel), 2.5 mg, methanol, 1000 mL).

Melting point \( <2.60\% \): 180 – 184°C

Purity: Related substances—(1) Dissolve 4 mg of curcumin for assay in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 50 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer chromatography \( <2.0\% \). Spot 5 \( \mu L \) each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of dichloromethane and methanol (19:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): the spots other than the principal spot at the Rt value of about 0.5 obtained from the sample solution are not more intense than the spot from the standard solution.

(2) Dissolve 1.0 mg of curcumin for assay in 5 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 10 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography \( <2.0\% \) according to the following conditions. Determine each peak from both solutions by the automatic integration method: the total area of the peaks other than the peak of curcumin obtained from the sample solution is not larger than the peak area of curcumin from the standard solution. Operating conditions

Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay under Turmeric.

Detector: A visible absorption photometer (wavelength: 422 nm).

Time span of measurement: About 4 times as long as the retention time of curcumin beginning after the solvent peak.

System suitability
Test for required detectability: Pipet 1 mL of the standard solution, add methanol to make exactly 20 mL. Confirm that the peak area of curcumin obtained from 10 μL of this solution is equivalent to 3.5 to 6.5% of that of curcumin from 10 μL of the standard solution.

System performance and system repeatability: Proceed as directed in the system suitability in the Assay under Turmeric.

Curcumin for component determination See curcumin for assay.

Cyanoacetic acid C₂H₂NO₂ White to light yellow crystals. Very soluble in water.

Content: not less than 99%. Assay—Weigh accurately about 300 mg of cyanoacetic acid, add 25 mL of water and 25 mL of ethanol (95) to dissolve, and titrate \( <2.50 \) with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS \( = 85.06 \text{ mg of C}_2\text{H}_2\text{NO}_2 \)

Cyanocobalamin C₁₉₈H₅₀CoN₁₄O₁₁P \[ Same as the namesake monograph \]

Cyanogen bromide TS To 100 mL of ice-cold water add 1 mL of bromine, shake vigorously, and add ice-cold potassium cyanide TS dropwise until the color of bromine just disappears. Prepare this test solution in a hood before use.

On handling this solution, be careful not to inhale its vapors, which are very toxic.

1-Cyanoguanidine NH₂C(NH)NHCN A white crystalline powder. Freely soluble in water.

Melting point \( <2.60°: 209 – 212°C \)

Loss on drying \( <2.41°: \) not more than 0.1% (1 g, 105°C, 3 hours).

Nitrogen content \( <1.00°: 66.0 – 67.3% \) (after drying).

Cyanopropylmethylyphenylsilicone for gas chromatography Prepared for gas chromatography.

6% Cyanopropylphenyl-94% dimethyl silicone polymer for gas chromatography Prepared for gas chromatography.

6% Cyanopropyl-6% phenyl-methyl silicone polymer for gas chromatography Prepared for gas chromatography.

7% Cyanopropyl-7% phenylmethylysilicone polymer for gas chromatography Prepared for gas chromatography.

Cycloartenyl ferulate for thin-layer chromatography C₃₀H₄₈O₆ A white to light brown, crystalline powder or powder. Soluble in acetone, slightly soluble in acetonitrile, and practically insoluble in water and in methanol. Melting point: about 155°C.

Identification (1) Determine the absorption spectrum of a solution in heptane (1 in 50,000) as directed under Ultraviolet-visible Spectrophotometry \( <2.24°: \) it exhibits maxima between 229 nm and 233 nm, between 289 nm and 293 nm, and between 313 nm and 317 nm.

(2) Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry \( <2.25°: \) it exhibits absorption at the wave numbers of about 2940 cm\(^{-1}\), 1691 cm\(^{-1}\), 1511 cm\(^{-1}\) and 1270 cm\(^{-1}\).

Purity Related substances—Dissolve 2.0 mg in 2 mL of acetone, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Proceed the test with 5 μL each of the sample solution and standard solution as directed in the Identification under Brown Rice: the spot other than the principle spot, having R\(_T\) value of about 0.4, obtained from the sample solution is not more intense than the spot from the standard solution.

Cyclohexane C₆H₁₂ \[ K 8464, Special class \]

Cyclohexylamine C₆H₅NH₂ A clear and colorless liquid, having a characteristic amine-like odor. Miscible with water, with \( N, N \)-dimethylformamide and with acetone.

Purity Related substances—Use cyclohexylamine as the sample solution. Separately, pipet 1 mL of cyclohexylamine, add hexane to make exactly 100 mL, and use this as the standard solution. Perform the test as directed in Thin-layer Chromatography \( <2.0°: \) Spot 5 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of ethyl acetate, methanol, ammonia water (28) and cyclohexane (6:2:1:1) to a distance of about 10 cm, and air-dry the plate. Allow the plate to stand in iodine vapor: the spot other than the principal spot obtained with the sample solution is not more intense than the spot with the standard solution.

Cyclohexylmethanol C₆H₁₂O A liquid having slight camphor odor. Soluble in ethanol (99.5).

Refractive index \( <2.45°: n_20^B: \) about 1.464

Biological point \( <2.57°: \) about 185°C

Cyclosporine U C₃₅H₅₆N₁₂O₁₂ White powder.

Optical rotation \( <2.49° \) \([α]_D^B: \) about \( −190°C \) (0.1 g, methanol, 20 mL 100 mm).

L-Cysteic acid C₇H₇NO₃S White powder.

Melting point \( <2.60°: \) about 260°C.

Optical rotation \( <2.49° \) \([α]_D^B: \) +7.5 – +9.0° (1.5 g, water, 20 mL, 100 mm).

L-Cysteine hydrochloride See L-cysteine hydrochloride monohydrate.

L-Cysteine hydrochloride monohydrate HSC₇H₇(CH(NH)₂COOH.HCl.H₂O \[ K 8470, Special class \]

L-Cystine HOOCCH(NH)₂SSCH₂CH(NH₂)COOH \[ K 9048, \( \lambda^{(-)}\)-Cystine, Special class \]

Cytochrome c An oxidase (molecular weight: 8000 – 13,000) derived from bovine cardiac muscle.

Absorbance \( <2.24° \) \( E_{cm}^{276} \): not less than 800 (after drying, 40 mg, 10,000 mL of 0.1 mol/L hydrochloric acid TS).

Dacuronium Bromide for thin-layer chromatography C₃₃H₃₁Br₂N₂O₆ White crystalline powder. Very soluble in water, freely soluble in ethanol (95), and practically insoluble in acetic anhydride. Hygrosopic.

Identification—Determine the infrared absorption spectrum of dacuronium bromide for thin-layer chromatography
according to the potassium bromide disk method under Infrared Spectrophotometry. It exhibits the absorptions at the wave numbers at about 2940 cm\(^{-1}\), 1737 cm\(^{-1}\), 1630 cm\(^{-1}\), 1373 cm\(^{-1}\), 1233 cm\(^{-1}\) and 1031 cm\(^{-1}\).

**Purity** Related substances—Dissolve 10 mg of dacuronic chloride for thin-layer chromatography in 2 mL of ethanol (95), and use this solution as the sample solution. Pipet 1 mL of this solution, add ethanol (95) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 mL each of the sample solution and standard solution as directed in the Purity (2). Related substances under Pancuronium Bromide: the spots other than the principal spot from the sample solution do not show more intense color than the spot from the standard solution. Water \(<2.48\): not more than 1.0% (1 g, volumetric titration, direct titration).

**Content** not less than 98.0%, calculated on the dehydrated basis. Assay—Weigh accurately about 0.2 g of dacuronic chloride for thin-layer chromatography, dissolve in 50 mL of acetic anhydride by warming, and titrate \(<2.50\) with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 34.53 mg of C\(_3\)H\(_5\)BrN\(_2\)O\(_3\).

**p,p’-DDD** (2,2-Bis(4-chlorophenyl)-1,1-dichloroethane)

\[ C\(_{14}\)H\(_9\)Cl\(_5\) \]

**Melting point** \(<2.60\): 108 – 110°C

**Purity** Related substances—Dissolve 10 mg of p,p’-DDD in hexane for purity of crude drug to make exactly 100 mL, pipet 1 mL of this solution, add hexane for purity of crude drug to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 1 mL each of the sample solution and standard solution (1) as directed under Gas Chromatography \(<2.02\) according to the following conditions, and measure each peak area from these solutions by the automatic integration method: the total peak area other than p,p’-DDD from the sample solution is not larger than the peak area of p,p’-DDD from the standard solution (1).

Operating conditions

Proceed the operating conditions in the Purity (2) under Crude Drugs Test \(<5.01\) except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add hexane for purity of crude drug to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of p,p’-DDD obtained from 1 μL of the standard solution (2) can be measured by the automatic integration method, and the peak height of p,p’-DDD from 1 μL of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About twice as long as the retention time of p,p’-DDD beginning after the solvent peak.

**p,p’-DDE** (2,2-Bis(4-chlorophenyl)-1,1-dichloroethylene)

\[ C\(_{14}\)H\(_9\)Cl\(_4\) \]

**Melting point** \(<2.60\): 88 – 90°C

**Purity** Related substances—Proceed as directed in the Purity of p,p’-DDD using the following standard solution (1).

Standard solution (1): Pipet 1 mL of the sample solution, and add hexane for purity of crude drug to make exactly 100 mL.

**o,p’-DDT** (1,1,1-Trichloro-2-(2-chlorophenyl)-2-(4-chlorophenyl)ethane)

\[ C\(_{14}\)H\(_9\)Cl\(_3\) \]

**Melting point** \(<2.60\): 73 – 75°C

**Purity** Related substances—Proceed as directed in the Purity of p,p’-DDD.

**p,p’-DDT** (1,1,1-Trichloro-2,2-bis(4-chlorophenyl)ethane)

\[ C\(_{14}\)H\(_9\)Cl\(_4\) \]

**Melting point** \(<2.60\): 108 – 110°C

**Purity** Related substances—Proceed as directed in the Purity of p,p’-DDD using the following standard solution (1).

Standard solution (1): Pipet 1 mL of the sample solution, and add hexane for purity of crude drug to make exactly 100 mL.

**n-Decyl trimethylammonium bromide** C\(_{15}\)H\(_{29}\)NBr

White powder. Melting point: about 232°C (with decomposition).

**Content** not less than 99%. Assay—Weigh accurately about 0.5 g of n-decyl trimethylammonium bromide, dissolve in 50 mL of water, and titrate \(<2.50\) with 0.1 mol/L silver nitrate VS (indicator: 1 mL of potassium chromate TS). Perform a blank determination in the same manner and make any necessary correction.

Each mL of 0.1 mol/L silver nitrate VS = 28.03 mg of C\(_{15}\)H\(_{29}\)NBr.

**0.005 mol/L n-Decyl trimethylammonium bromide TS**

Dissolve 6.94 g of potassium dihydrogen phosphate, 3.22 g of disodium hydrogen phosphate dodecahydrate and 1.40 g of n-decyl trimethylammonium bromide in water to make 1000 mL.

**Defibrinated blood of rabbit** Transfer 100 mL of blood obtained from rabbit to a flask, put in about 20 glass balls 8 mm in diameter, shake for 5 minutes gently, and filter through gauze. Prepare before use.

**Decolorized fuschin TS** Add 1 g of fuschin in 100 mL of water, heat at about 50°C, then cool with occasional shaking. After standing for 48 hours, mix and filter. To 4 mL of the filtration add 6 mL of hydrochloric acid and water to make 100 mL. Use after standing for at least 1 hour. Prepare before use.

**n-Decyl trimethylammonium bromide for assay** C\(_{15}\)H\(_{29}\)N\(_2\)O\(_7\)

Yellow, crystals or crystalline powder. It is sparingly soluble in methanol, and slightly soluble in water and in ethanol (99.5).

**Melting point**: about 240°C (with decomposition).

**Absorbance** \(<2.20\) E\(_{1%}\) (333 nm): 577 – 642 (3 mg, water, 500 mL). Use the sample dried in a desiccator (silica gel) for not less than 1 hour for the test.

**Purity** (1) Related substances 1—Dissolve 5.0 mg of dehydrocorydaline nitrate for assay in 1 mL of a mixture of
water and methanol (1:1), and use this solution as the sample solution. Pipet 0.5 mL of the sample solution, add a mixture of water and methanol (1:1) to make exactly 50 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.01>. Spot 5 μL of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop immediately with a mixture of methanol, a solution of ammonium acetate (3 in 10) and acetic acid (100) (20:1:1) to a distance of about 30 cm, and air-dry the plate. Spray Dragendorff’s TS on the plate, air-dry, and spray sodium nitrite TS; the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

(2) Related substances—Dissolve 5.0 mg of dehydrocorydaline nitrate for assay in 10 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 5 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and measure each peak area from these solutions by the automatic integration method: the total area of peaks other than dehydrocorydaline from the sample solution is not larger than the peak area of dehydrocorydaline from the standard solution.

Operating conditions
Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay under Corydalis Tuber.
Detector: Ultraviolet absorption photometer (wavelength: 230 nm).
Time span of measurement: About 3 times as long as the retention time of dehydrocorydaline, beginning after the peak of nitric acid.
System suitability
System performance and system repeatability: Proceed as directed in the system suitability in the Assay under Corydalis Tuber.
Test for required detectability: To exactly 1 mL of the standard solution add the mobile phase to make exactly 20 mL. Confirm that the peak area of dehydrocorydaline obtained from 10 μL of the solution is equivalent to 3.5 to 6.5% of that from 5 μL of the standard solution.

Dehydrocorydaline nitrate for component determination
See dehydrocorydaline nitrate for assay.

Demethoxycurcumin C20H18O5 Yellow to orange crystalline powder or powder. Sparingly soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: 166 – 170°C.

Identification Determine the absorption spectrum of a solution of demethoxycurcumin in methanol (1 in 400,000) as directed under Ultraviolet-visible Spectrophotometry <2.2.4>: it exhibits a maximum between 415 nm and 420 nm.

Purity Related substances—(1) Dissolve 4 mg of demethoxycurcumin in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test as directed under Thin-layer Chromatography <2.01>. Spot 5 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of dichloromethane and methanol (19:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm); the spots other than the principal spot at the Rf value of about 0.3 obtained from the sample solution are not more intense than the spot from the standard solution.

(2) Dissolve 1.0 mg of demethoxycurcumin in 5 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak from both solutions by the automatic integration method: the total area of the peaks other than the peak of demethoxycurcumin obtained from the sample solution is not larger than the peak area of demethoxycurcumin from the standard solution.

Operating conditions
Column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay under Turmeric.
Detector: A visible absorption photometer (wavelength: 422 nm).
Time span of measurement: About 4 times as long as the retention time of demethoxycurcumin beginning after the solvent peak.

System suitability
Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of demethoxycurcumin obtained from 10 μL of this solution is equivalent to 3.5 to 6.5% of that of demethoxycurcumin from 10 μL of the standard solution.
System performance and system repeatability: Proceed as directed in the system suitability in the Assay under Turmeric.

N-Demethylerythromycin C36H65NO13 White pow- der.

N-Demethylroxithromycin C40H74N2O15 White pow- der.

Identification—Determine the infrared absorption spectrum of a solution of the substance to be tested in chloroform (1 in 20) as directed in the solution method under Infrared Spectrophotometry <2.25> using a 0.1-mm cell made of potassium bromide: it exhibits absorption at the wave numbers of about 3600 cm⁻¹, 3520 cm⁻¹, 3450 cm⁻¹, 3340 cm⁻¹, 1730 cm⁻¹ and 1627 cm⁻¹.

2'-Deoxyuridine for liquid chromatography C12H12N2O5 White, crystalline powder.

Melting point <2.60>: 162 – 166°C
Purity—Dissolve 3.0 mg of 2'-deoxyuridine for liquid chromatography in diluted methanol (1 in 25) to make 50 mL. Perform the test with 10 μL of this solution as directed under Liquid Chromatography <2.01> according to the operating conditions in the Purity under Idoxuridine Ophthalmic Solution. Measure each peak area by the automatic integration method to the range about twice the retention time of 2'-deoxyuridine, and calculate the amount of 2'-deoxyuridine by the area percentage method: it shows a purity of not less than 98.5%.
Deuterochloroform (CDCl₃), heavy water (D₂O), etc.

The maximum wavelength at about 262 nm.

Resonance spectroscopy

CD₃OD Prepared for nuclear magnetic resonance spectroscopy.

NMR solvents

Deuterated dimethylsulfoxide for nuclear magnetic resonance spectroscopy (CD₃)₂SO Prepared for nuclear magnetic resonance spectroscopy.

Deuterated formic acid for nuclear magnetic resonance spectroscopy DCOOD Prepared for nuclear magnetic resonance spectroscopy.

Deuterated hydrochloric acid for nuclear magnetic resonance spectroscopy DCl Prepared for nuclear magnetic resonance spectroscopy.

Deuterated methanol for nuclear magnetic resonance spectroscopy CD₂OD Prepared for nuclear magnetic resonance spectroscopy.

Deuterated NMR solvents Prepared for nuclear magnetic resonance spectroscopy. For example: deuterated dimethylsulfoxide [CD₃]₂SO, deuterated pyridine (C₅D₅N), deuterochloroform (CDCl₃), heavy water (D₂O), etc.

Deuterated pyridine for nuclear magnetic resonance spectroscopy C₅D₅N Prepared for nuclear magnetic resonance spectroscopy.

Deuterochloroform for nuclear magnetic resonance spectroscopy CDCl₃ Prepared for nuclear magnetic resonance spectroscopy.

Devarda’s alloy [K 8653, For Nitrogen analysis]

Diacetyl CH₃COCOCH₃ A yellow to yellow-green, clear liquid, having a strong, pungent odor. Miscible with ethanol (95) and with diethyl ether, and freely soluble in water.

Congealing point <2.40>: −2.0 to −5.5°C

Refractive index <2.45> nD: 1.390 – 1.398

Specific gravity <2.56> d20°: 0.98 – 1.00

Boiling point <2.57>: 85 – 91°C

Purity Clarity of solution—Dissolve 1.0 g of diacetyl in 10 mL of water: the solution is clear.

Content: not less than 98.5%. Assay—Weigh accurately about 5 mg of 2′-deoxyuridine for liquid chromatography, previously dried in vacuum at 60°C for 3 hours, and dissolve in water to make exactly 250 mL. Pipet 10 mL of this solution, dilute with water to make exactly 20 mL. Perform the test with this solution as directed under Ultraviolet-visible Spectrophotometry <2.24>, and determine absorbance A at the maximum wavelength at about 262 nm.

Amount (mg) of deoxyuridine (C₉H₁₂N₂O₅)

\[ A = \frac{A}{447} \times 5000 \]

Dermatan sulfate Dermatan sulfate is mucopolysaccharide purified from the skin and small intestines of pigs by alkaline extraction, followed by digestion with protease and fractionation by alcohol. When cellulose acetate membrane electrophoresis of dermatan sulfate is performed and the membrane is stained in a toluidine blue O solution (1 in 200), a single band appears.

Operation conditions of cellulose acetate membrane electrophoresis—Cellulose acetate membrane: 6 cm in width and 10 cm in length.

Mobile phase: Dissolve 52.85 g of calcium acetate monohydrate in water to make 100 mL.

Run time: 3 hours (1.0 mA/cm)

Deuterated dimethylsulfoxide for nuclear magnetic resonance spectroscopy (CD₃)₂SO Prepared for nuclear magnetic resonance spectroscopy.

Deuterated pyridine for nuclear magnetic resonance spectroscopy DCOOD Prepared for nuclear magnetic resonance spectroscopy.

Deuterated hydrochloric acid for nuclear magnetic resonance spectroscopy DCl Prepared for nuclear magnetic resonance spectroscopy.

Deuterated methanol for nuclear magnetic resonance spectroscopy CD₂OD Prepared for nuclear magnetic resonance spectroscopy.

Deuterated NMR solvents Prepared for nuclear magnetic resonance spectroscopy. For example: deuterated dimethylsulfoxide [CD₃]₂SO, deuterated pyridine (C₅D₅N), deuterochloroform (CDCl₃), heavy water (D₂O), etc.

Deuterated pyridine for nuclear magnetic resonance spectroscopy C₅D₅N Prepared for nuclear magnetic resonance spectroscopy.

Deuterochloroform for nuclear magnetic resonance spectroscopy CDCl₃ Prepared for nuclear magnetic resonance spectroscopy.

Devarda’s alloy [K 8653, For Nitrogen analysis]

Diacetyl CH₃COCOCH₃ A yellow to yellow-green, clear liquid, having a strong, pungent odor. Miscible with ethanol (95) and with diethyl ether, and freely soluble in water.

Congealing point <2.40>: −2.0 to −5.5°C

Refractive index <2.45> nD: 1.390 – 1.398

Specific gravity <2.56> d20°: 0.98 – 1.00

Boiling point <2.57>: 85 – 91°C

Purity Clarity of solution—Dissolve 1.0 g of diacetyl in 10 mL of water: the solution is clear.

Content: not less than 98.5%. Assay—Weigh accurately about 0.4 g of diacetyl, add exactly 75 mL of hydroxylamine TS, and heat on a water bath for 1 hour under a reflux condenser. After cooling, titrate <2.50> the excess hydroxylamine with 0.5 mol/L hydrochloric acid VS until the color of the solution changes from blue to yellow-green through green (indicator: 3 drops of bromophenol blue TS). Perform a blank determination in the same manner.

Each mL of 0.5 mol/L hydrochloric acid VS

\[ = 21.52 \text{ mg of C}_2\text{H}_4\text{O}_2 \]

Diacetyl TS Dissolve 1 mL of diacetyl in water to make 100 mL, and dilute 5 mL of this solution with water to make 100 mL. Prepare before use.

2,3-Diaminonaphthalene C₁₀H₁₀N₂ Light yellow-brown crystals or powder. Slightly soluble in ethanol (95) and in diethyl ether, and practically insoluble in water.

Melting point <2.60>: 193 – 198°C

Sensitivity—Pipe tet separately 40 mL each of the selenium standard solution and diluted nitric acid (1 in 60) as the blank solution into beakers, and to these solutions add ammonia solution (28) to adjust the pH to between 1.8 and 2.2. Dissolve 0.2 g of hydroxylaminommonium chloride in each of these solutions under gentle shaking, add 5 mL of 2,3-diaminonaphthalene TS, mix by shaking, and allow to stand for 100 minutes. Transfer these solutions to separators separately, rinse the beakers with 10 mL of water, add these rinsings to the separators, extract each with 5.0 mL of cyclohexane by thorough shaking for 2 minutes, and centrifuge the cyclohexane layers to remove moisture. When the absorbance at 378 nm of cyclohexane extract obtained from selenium standard solution is determined using the solution obtained from the blank solution as the reference solution as directed under Ultraviolet-visible Spectrophotometry <2.24>, it is not less than 0.08.

Selenium standard solution—Weigh accurately 40 mg of selenium, dissolve in 100 mL of diluted nitric acid (1 in 2), by heating on water bath if necessary, and add water to make exactly 1000 mL. Pipet 5 mL of this solution, and add water to make exactly 200 mL. Pipet 2 mL of this solution, and add diluted nitric acid (1 in 60) to make exactly 50 mL. Prepare before use. This solution contains 0.04 µg of selenium (Se) per mL.

2,4-Diaminophenol dihydrochloride C₆H₇N₂O.2HCl Pale yellow-brown to grayish yellow crystalline powder. Freely soluble in water, slightly soluble in ethanol (95), and practically insoluble in diethyl ether.

Purity Clarity of solution—Dissolve 1.0 g of 2,4-diaminophenol hydrochloride in 20 mL of water: the solution is clear or a slight turbidity is produced.

Loss on drying <2.47>: not more than 0.5% (1 g, 105°C, 3 hours).

Residue on ignition <2.44>: not more than 0.5% (1 g).

Content: not less than 98.0%. Assay—Weigh accurately about 0.2 g of 2,4-diaminophenol hydrochloride, dissolve in 50 mL of water, and titrate <2.50> with 0.1 mol/L silver nitrate VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L silver nitrate VS

\[ = 9.853 \text{ mg of C}_6\text{H}_7\text{N}_2\text{O.2HCl} \]
2,4-Diaminophenol dihydrochloride TS
Dissolve 1 g of 2,4-diaminophenol hydrochloride and 20 g of sodium bisulfite in 100 mL of water, and filter, if necessary.

2,4-Diaminophenol See 2,4-diaminophenol dihydrochloride.

2,4-Diaminophenol hydrochloride TS
See 2,4-diaminophenol dihydrochloride TS.

Diammonium hydrogen citrate C$_6$H$_8$N$_2$O$_7$ • H$_2$O [K 8284, Special class]

Diammonium hydrogen phosphate (NH$_4$)$_2$HPO$_4$ [K 9016, Special class]

Diazepam for assay C$_{16}$H$_{13}$ClN$_2$O [Same as the monograph, Diazepam. When dried, it contains not less than 99.0% of diazepam (C$_{16}$H$_{15}$ClN$_2$O), and meets the additional following requirement.]

Purity Related substance—Dissolve 50 mg in 10 mL of water, add methanol to make 100 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add methanol to make exactly 100 mL. Pipet 2 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography (2.01) according to the following conditions, and determine each peak area by the automatic integration method: the area of the peak other than diazepam from the sample solution is not larger than the peak area of diazepam from the standard solution.

Operating conditions
Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay under Diazepam Tablets.

Time span of measurement: About 4.5 times as long as the retention time of diazepam, beginning after the solvent peak.

System suitability
System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of diazepam are not less than 5000 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of diazepam is not more than 2.0%.

Diazobenzenesulfonylic acid TS
Weigh 0.9 g of sulfanilic acid, previously dried at 105°C for 3 hours, dissolve it in 10 mL of dilute hydrochloric acid by heating, and add water to make 100 mL. Pipet 3.0 mL of this solution, add 2.5 mL of sodium nitrite TS, and allow to stand for 5 minutes while cooling with ice. Then add 5 mL of sodium nitrite TS and water to make 100 mL, and allow to stand in ice water for 15 minutes. Prepare before use.

Diazobenzenesulfonylic acid TS, concentrated
Weigh 0.2 g of sulfanilic acid, previously dried at 105°C for 3 hours, dissolve it in 20 mL of 1 mol/L hydrochloric acid TS by warming. Cool this solution with ice, and add 2.2 mL of a solution of sodium nitrite (1 in 25) dropwise under stirring. Allow to stand in ice water for 10 minutes, and add 1 mL of a solution of sulfaminic acid (1 in 20). Prepare before use.

Diazobenzenesulfonylic acid TS, concentrated
Weigh accurately 0.9 g of sulfanilic acid, add 0.9 mL of hydrochloric acid and 20 mL of water, and dissolve by heating. After cooling, filter, and dilute the filtrate with water to make exactly 100 mL. Pipet 1.5 mL of this solution, cool in an ice bath, and add exactly 1 mL of sodium nitrite solution (1 in 20) dropwise, while shaking. Cool in an ice bath for 10 minutes, add cold water to make exactly 50 mL. Store in a cold place, and use within 8 hours.

Dibasic ammonium phosphate See diammominhydrogen phosphate.

0.5 mol/L Dibasic sodium phosphate TS
See 0.5 mol/L disodium hydrogen phosphate TS.

Dibekacin sulfate C$_{18}$H$_{37}$N$_5$O$_8$.H$_2$SO$_4$
[Same as the namesake monograph]

Dibenz[a,h]anthracene C$_{22}$H$_{14}$ Very pale yellow to green-yellow crystalline powder or powder. Practically insoluble in water, in methanol and in ethanol (99.5). Melting point: 265–270°C.

Identification Perform the test with dibenz[a,h]anthracene as directed in the Purity: the mass spectrum of the main peak shows a molecular ion peak (m/z 278) and a fragment ion peak (m/z 139).

Purity Related substances—Dissolve 3.0 mg of dibenz[a,h]anthracene in methanol to make 100 mL, and use this solution as the sample solution. Perform the test with 1
1.02 g of disodium hydrogen phosphate, anhydrous and 6.80 g of potassium dihydrogen phosphate in 1000 mL of water to make exactly 50 mL. Pipet 5 mL of this solution, add a mixture of the solution containing 1.02 g of disodium hydrogen phosphate and 6.80 g of potassium dihydrogen phosphate in 1000 mL of water and methanol (1:1) to make exactly 20 mL, and use this solution as the sample solution. Separately, weigh accurately about 8 mg of acetic acid (100), add 25 mL of methanol, and add the solution containing 1.02 g of disodium hydrogen phosphate and 6.80 g of potassium dihydrogen phosphate in 1000 mL of water to make exactly 20 mL, and use this solution as the control solution. Perform the test with exactly 20 mL of each of the sample solution and control solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine each peak area by the automatic integration method. After making correction for the peak areas based on the baseline and the peak of acetic acid on the chromatogram obtained with the sample solution, calculate the amount of \( N,N' \)-dibenzylethylenediamine by the area percentage method.

### System suitability

- **Detector:** An ultraviolet absorption photometer (wavelength: 220 nm).
- **Column:** A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecytrimethylsilane silica gel for liquid chromatography (5 \( \mu \)m in particle diameter).
- **Column temperature:** A constant temperature of about 40\({}^\circ\)C.
- **Mobile phase:** A mixture of water, methanol and 0.25 mol/L potassium dihydrogen phosphate TS, pH 3.5 (11:7:2).
- **Flow rate:** Adjust the flow rate so that the retention time of \( N,N' \)-dibenzylethylenediamine is about 4 minutes.
- **Time span of measurement:** About 5 times as long as the retention time of \( N,N' \)-dibenzylethylenediamine.

### Related substances

- **System suitability**
  - **System performance:** Dissolve an amount of Benzylpenicillin Benzyathine, equivalent to about 85,000 Units, in 25 mL of methanol, add a solution containing 1.02 g of disodium hydrogen phosphate and 6.80 g of potassium dihydrogen phosphate in 1000 mL of water to make exactly 50 mL. Pipet 5 mL of this solution, add a mixture of the solution containing 1.02 g of disodium hydrogen phosphate and 6.80 g of potassium dihydrogen phosphate in 1000 mL of water and methanol (1:1) to make exactly 20 mL. When the procedure is run with 20 mL of this solution under the above operating conditions, \( N,N' \)-dibenzylethylenediamine and benzylpenicillin are eluted in this order with the resolution between these peaks being not less than 20.
  - **System repeatability:** When the test is repeated 6 times with 20 mL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of \( N,N' \)-dibenzylethylenediamine is not more than 2.0%.

### 2.6-Dibromo-N-chloro-1,4-benzoquinone monoimine

- **CAS number:** \( \text{C}_8\text{H}_6\text{Br}_2\text{CINO} \) [K 8491, Special class]

standard class. The water content is not more than 0.01

2-(2-ethoxyethoxy)ethanol Clear, colorless liquid, of which the boiling point is about 203

water is alkaline, and readily absorbs carbon dioxide in air.

Specific gravity <2.50> d^20_1: 0.702 – 0.708

Diethanolamine hydrochloride See 2,2’-iminodiethanol hydrochloride.

Diethylamine (C_2H_5)NH A clear, colorless liquid, having an amine-like odor. Miscible with water and with ethanol (95). The solution in water is alkaline, and readily absorbs carbon dioxide in air.

Specific gravity <2.50> d^20_1: 1.118 – 1.120

Diethylylm glycol adipinate for gas chromatography Prepared for gas chromatography.

Diethylene glycol monoethyl ether (C_2H_5OCH_2CH_2)OH Clear and colorless liquid, miscible with water.

Specific gravity <2.50> d^20_1: 0.940 – 0.950

Distilling range <2.50>: 158 – 160°C, not less than 95 vol%.

Diethylene glycol monoethyl ether for water determination See Water Determination <2.40>.

Diethylene glycol succinate ester for gas chromatography Prepared for gas chromatography.

Diethylene glycol succinate polyester for gas chromatography Prepared for gas chromatography.

Diethylym ether C_2H_5OC_2H_5 [K 8103, Special class]

Diethyl ether, dehydrated C_2H_5OC_2H_5 [K 8103, Special class. The water content is not more than 0.01%].

Diethyl ether for purity of crude drug C_2H_5OC_2H_5 [K 8103, Special class]. Use diethyl ether meeting the following additional specification. Evaporate 300.0 mL of diethyl ether for purity of crude drug in vacuum at a temperature not higher than 40°C, add the diethyl ether to make exactly 1 mL, and use this solution as the sample solution. Separately, dissolve 2.0 mg of γ-BHC in hexane for purity of crude drug to make exactly 100 mL. Pipet 1 mL of this solution, and add hexane for purity of crude drug to make exactly 100 mL. Pipet 2 mL of this solution, add hexane for purity of crude drug to make exactly 100 mL, and use this solution as the standard solution I. Perform the test with 1 μL each of the sample solution and standard solution I as directed under Gas Chromatography <2.02> according to the following operating conditions, and determine each peak area by the automatic integration method: the total area of peaks other than the solvent peak from the sample solution is not larger than the peak area of γ-BHC from the standard solution I.

Operating conditions
Proceed the operating conditions in the Purity (2) under the Crude Drugs Test <5.02> except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution I, add hexane for purity of crude drug to make exactly 20 mL, and use this solution as the standard solution II. Adjust the detection sensitivity so that the peak area of γ-BHC obtained from 1 μL of the standard solution II can be measured by the automatic integration method, and the peak height of γ-BHC from 1 μL of the standard solution I is about 20% of the full scale.

Time span of measurement: About three times as long as the retention time of γ-BHC beginning after the peak of solvent.

N,N-Diethyl-N’-1-naphthylethylenediamine oxalate C_18H_32N_4O_4 A white crystalline powder.

Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3340 cm⁻¹, 2940 cm⁻¹, 1581 cm⁻¹, 1536 cm⁻¹, 1412 cm⁻¹, 789 cm⁻¹, 774 cm⁻¹ and 721 cm⁻¹.

Purity Clarity of solution—To 0.1 g add 20 mL of water, and dissolve by warming: the solution is clear.

N,N-Diethyl-N’-1-naphthylethylenediamine oxalate-ace tone TS Dissolve 1 g of N,N-diethyl-N’-1-naphthylethylenediamine oxalate in 100 mL of a mixture of acetone and water (1:1). Prepare before use.

N,N-Diethyl-N’-1-naphthylethylenediamine oxalate TS Dissolve 1 g of N,N-diethyl-N’-1-naphthylethylenediamine oxalate in water to make 1000 mL.

Diethyl phthalate C_8H_6(COOC_2H_5)_2 A colorless, clear liquid.

Refractive index <2.45> n^20_2: 1.500 – 1.505

Purity Related substances—To 1 mL of diethyl phthalate add a solution of tetra-n-heptylammonium bromide in a mixture of water, acetonitrile and methanol (137:80:23) (2 in 625) to make 100 mL. To 6 mL of this solution add a solution of tetra-n-heptylammonium bromide in a mixture of water, acetonitrile and methanol (137:80:23) (2 in 625) to make 50 mL, and use this solution as the sample solution. Perform the test with 10 μL of the sample solution as directed in the Assay under Cefetamet Pivoxil Hydrochloride: any peaks other than peaks of diethyl phthalate and the solvent are not observed.
Diethyl terephthalate \( \text{C}_2\text{H}_4\text{(COOC}_2\text{H}_5\text{)}_2 \) White to pale brownish white, crystalline or mass.  
*Melting point* \( <2.60^\circ \text{C} \); \( >44 - 46^\circ \text{C} \)
*Content*: not less than \( 99\% \). Assay—Dissolve 100 mg of diethyl terephthalate in 10 mL of methanol. Perform the test with \( 2 \mu\text{L} \) of this solution as directed under Gas Chromatography \( <2.02> \) according to the following conditions, and determine the area of each peak by the automatic integration method.

\[
\text{Content (\%)} = \frac{\text{peak area of diethyl terephthalate}}{\text{total of all peak areas}} \times 100
\]

*Operating conditions*
- **Detector**: Hydrogen flame-ionization detector.
- **Column**: A glass tube 4 mm in inside diameter and 2 m in length, packed with Shimalted W(AW, DMCS) coated with SE-30 in 10% (177 – 250 \( \mu\text{m} \) in particle diameter).
- **Column temperature**: A constant temperature of about \( 200^\circ \text{C} \).
- **Carrier gas**: Helium.
- **Flow rate**: Adjust the flow rate so that the retention time of diethyl terephthalate is between 6 and 7 minutes.
- **Time span of measurement**: About 5 times as long as the retention time of diethyl terephthalate beginning after the solvent peak.

**Difenidol hydrochloride** \( \text{C}_9\text{H}_{12}\text{NO}_4\text{HCl} \) [Same as the namesake monograph]

**Digitonin** \( \text{C}_{22}\text{H}_{26}\text{N}_2\text{O}_4\text{HCl} \) [Same as the monograph Dihydrocodeine Phosphate. It contains not less than \( 99.0 \% \) of dihydrocodeine phosphate \( \text{C}_{18}\text{H}_{23}\text{NO}_3\text{H}_3\text{PO}_4 \), calculated on the dried basis.]

**Dihydrocodeine phosphate for assay** \( \text{C}_{18}\text{H}_{23}\text{NO}_3\text{H}_3\text{PO}_4 \) [Same as the namesake monograph]

**Dihydroergocristine mesilate for thin-layer chromatography** \( \text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_4 \) A pale yellowish white powder.  
*Purity* Related substances—Dissolve 6 mg of dihydroergocristine mesilate for thin-layer chromatography in exact 100 mL of a mixture of chloroform and methanol (9:1), and perform the test with 5 \( \mu\text{L} \) of this solution as directed in the Purity (3) under Zidovudine: spots other than the principal spot with an RF value of about 0.23 are not observed.

**3,4-Dihydroxy-6-hydroxy-2(1H)-quinolinone** \( \text{C}_7\text{H}_3\text{NO}_2 \) A white to light brown powder or granule. Melting point: about \( 240^\circ \text{C} \) (with decomposition).

**Identification**—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry \( <2.25> \); it exhibits absorption at the wave numbers of about 3210 cm\(^{-1}\), 1649 cm\(^{-1}\), 1502 cm\(^{-1}\), 1252 cm\(^{-1}\), and 816 cm\(^{-1}\).

**2,4-Dihydroxybenzoic acid** \( \text{C}_8\text{H}_4\text{(COOC}_2\text{H}_5\text{)}_2 \) [Same as the namesake monograph]

**1,3-Dihydroxynaphthalene** \( \text{C}_9\text{H}_4\text{(OH)}_2 \) Purple-brown, crystals or powder. Freely soluble in water and in ethanol (95).

*Melting point* \( <2.60^\circ \text{C} \); about \( 125^\circ \text{C} \)

**2,7-Dihydroxynaphthalene** \( \text{C}_9\text{H}_4\text{(OH)}_2 \)

*Purity* not less than \( 97.0\% \).

**2,7-Dihydroxynaphthalene TS** Dissolve 0.10 g of 2,7-dihydroxynaphthalene in 1000 mL of sulfuric acid, and allow to stand until the yellow color initially developed disappears. If the solution is blackened notably, prepare freshly.

**Diisopropylamine** \( [(\text{CH}_3)_2\text{CH}]_2\text{NH} \) Colorless, clear liquid, having an amine-like odor. Miscible with water and with ethanol (95). The solution in water is alkaline.

*Refractive index* \( <2.45> \) \( n_2^\circ \): 1.391 – 1.394  
*Specific gravity* \( <2.56> \) \( d_2^\circ \): 0.715 – 0.722

**Diltiazem hydrochloride** \( \text{C}_2\text{H}_{18}\text{N}_2\text{O}_4\text{S.HCl} \) [Same as the namesake monograph]

**Dilute acetic acid** See acetic acid, dilute.

**Dilute bismuth subnitrate-potassium iodide TS for spray** Dissolve 10 g of \( \text{L-tartaric acid} \) in 50 mL of water, and add 5 mL of bismuth subnitrate TS.

**Dilute bromophenol blue TS** See bromophenol blue TS, dilute.

**Dilute p-dimethylaminobenzaldehyde-ferric chloride TS** See 4-dimethylaminobenzaldehyde-ferric chloride TS, dilute.

**Dilute 4-dimethylaminobenzaldehyde-iron (III) chloride TS** See 4-dimethylaminobenzaldehyde-iron (III) chloride TS, dilute.

**Diluted ethanol** See ethanol, diluted.

**Dilute ethanol** See ethanol, dilute.

**Dilute ferric ammonium sulfate TS** See ammonium iron...
Dilute ferric chloride TS See iron (III) chloride TS, dilute.

Dilute hydrochloric acid See hydrochloric acid, dilute.

Dilute hydrogen peroxide TS See hydrogen peroxide TS, dilute.

Dilute iodine TS See iodine TS, dilute.

Dilute iron-phenol TS See iron-phenol TS, dilute.

Dilute lead subacetate TS See lead subacetate TS, dilute.

Dilute methyl red TS See methyl red TS, dilute.

Dilute nitric acid See nitric acid, dilute.

Dilute potassium hydroxide-ethanol TS See potassium hydroxide-ethanol TS, dilute.

Dilute sodium hydroxide TS See sodium hydroxide TS, dilute.

Dilute sulfuric acid See sulfuric acid, dilute.

Dilute thymol blue TS See thymol blue TS, dilute.

Dilute vanadium pentoxide TS See vanadium (V) oxide TS, dilute.

Dimedon C6H12O2 White to pale yellow, crystalline powder. Melting point <2.60°: 145 – 149°C

Dimenhydrinate for assay C17H21NO.C7H7ClN4O2 [Same as the monograph Dimenhydrinate. When dried, it contains not less than 53.8% and not more than 54.9% of diphenhydramine (C17H21NO) and not more than 46.1% of 8-chlorotheophylline (C12H17N2O).]

Dimethoxymethane C3H8O2 Colorless, clear and volatile liquid. Miscible with methanol, with ethanol (95) and with diethyl ether. N,N-Dimethylacetamide CH2CON(CH3)2 Clear and colorless liquid. Specific gravity <2.50°: d: 0.938 – 0.945 (Method 3). Boiling point <2.57°: 163 – 165°C Water <2.48°: not more than 0.2% (0.1 g, Coulometric titration). Purity—Perform the test with 3 μL of N,N-dimethylacetamide as directed under Gas Chromatography <2.02> according to the following conditions, determine each peak area by the automatic integration method, and calculate the amount of N,N-dimethylacetamide by the area percentage method: not less than 98.0%.

Operating conditions Detector: A hydrogen flame-ionization detector. Column: A fused silica column 0.25 mm in inside diameter and 30 m in length, coated the inside surface 0.5 μm in thickness with polyethylene glycol 20 M for gas chromatography.

Column temperature: The sample is injected at a constant temperature of about 70°C, keep this temperature for 1 minute, then raise to 200°C in a rate of 10°C per minute, and keep 200°C for 3 minutes.

Time span of measurement: About 2 times as long as the retention time of N,N-dimethylacetamide.

System suitability Test for required detection: To exactly 1.0 g of N,N-dimethylacetamide add acetone to make exactly 100 mL. Pipet 5 mL of this solution, and add acetone to make exactly 50 mL. Confirm that the peak area of N,N-dimethylacetamide obtained from 3 μL of this solution is equivalent to 40 to 60% of the full-scale.

System repeatability: When the test is repeated with 3 μL of N,N-dimethylacetamide under the above operating conditions, the relative standard deviation of the peak area of N,N-dimethylacetamide is not more than 2.0%.

Dimethylyamine (CH3)2NH Colorless, clear liquid, having amine-like, characteristic odor. It is miscible with water and with ethanol (99.5). It is alkaline. Specific gravity <2.50°: d: 0.85 – 0.93 Content: 38.0 – 45.0%. Assay—Weigh accurately about 1 g of dimethylyamine, transfer to a flask containing exactly 20 mL of 0.5 mol/L sulfuric acid VS, and titrate <2.50> the excess sulfuric acid with 1 mol/L sodium hydroxide VS (indicator: 2 drops of methyl red TS). Perform a blank determination in the same manner.

Each mL of 0.5 mol/L sulfuric acid VS = 45.08 mg of (CH3)2NH

4-Dimethylaminooantipyrine C13H17N3O Colorless or white crystals, or a white crystalline powder. Purity Related substances—Proceed the test with 5 μL of a solution of 4-dimethylaminooantipyrine (1 in 2000) as directed in the Assay under Cefpime Sodium, determine each peak area in a range of about 2 times as long as the retention time of 4-dimethylaminooantipyrine after the solvent peak by the automatic integration method, and calculate the total amount of the peaks other than 4-dimethylaminooantipyrine by the area percentage method: not more than 1.8%.

(Dimethylamino)azo(benzensulfonyl chloride C14H10ClN2O5 Prepared for amino acid analysis or biochemistry.

p-Dimethylaminobenzaldehyde See 4-dimethylaminobenzaldehyde.

4-Dimethylaminobenzaldehyde (CH3)2NC6H4CHO [K 8496, p-Dimethylaminobenzaldehyde, Special class]

p-Dimethylaminobenzaldehyde-ferric chloride TS See 4-dimethylaminobenzaldehyde-ferric chloride TS, dilute

p-Dimethylaminobenzaldehyde-hydrochloric acid TS See 4-dimethylaminobenzaldehyde-hydrochloric acid TS.
4-Dimethylaminobenzaldehyde-hydrochloric acid TS  
Dissolve 1.0 g of 4-dimethylaminobenzaldehyde in 50 mL of hydrochloric acid while cooling, and add 50 mL of ethanol (95).

4-Dimethylaminobenzaldehyde-iron (III) chloride TS  
Dissolve 0.125 g of 4-dimethylaminobenzaldehyde in a cold mixture of 65 mL of sulfuric acid and 35 mL of water, then add 0.05 mL of iron (III) chloride TS. Use within 7 days.

4-Dimethylaminobenzaldehyde-iron (III) chloride TS, dilute  
To 80 mL of water add carefully 100 mL of 4-dimethylaminobenzaldehyde-iron (III) chloride TS and 0.15 mL of iron (III) chloride TS, while cooling with ice.

\( p \)-Dimethylaminobenzaldehyde TS  
See 4-dimethylaminobenzaldehyde TS.

4-Dimethylaminobenzaldehyde TS  
Dissolve 10 g of 4-dimethylaminobenzaldehyde in a cold mixture of 90 mL of sulfuric acid and 10 mL of water. Prepare before use.

\( p \)-Dimethylaminobenzaldehyde TS for spraying  
See 4-dimethylaminobenzaldehyde TS for spraying.

4-Dimethylaminobenzaldehyde TS for spraying  
Dissolve 1.0 g of 4-dimethylaminobenzaldehyde in 20 mL of dilute sulfuric acid. Prepare before use.

\( p \)-Dimethylaminobenzylidene rhodanine  
See 4-dimethylaminobenzylidene rhodanine.

4-Dimethylaminobenzylidene rhodanine  
\( C_{12}H_{12}N_2O_2 \) [K 8495, Special class]

\( p \)-Dimethylaminobenzylidene rhodanine TS  
See 4-dimethylaminobenzylidene rhodanine TS.

4-Dimethylaminobenzylidene rhodanine TS  
Dissolve 20 mg of 4-dimethylaminobenzylidene rhodanine in acetone to make 100 mL.

\( p \)-Dimethylaminocinnamaldehyde  
See 4-dimethylaminocinnamaldehyde.

4-Dimethylaminocinnamaldehyde  
\( C_9H_7NO \) Orange crystals or crystalline powder, having a characteristic odor. Freely soluble in dilute hydrochloric acid, sparingly soluble in ethanol (95) and in diethyl ether, and practically insoluble in water.

Melting point \(<2.60\%>: 140 – 142^\circ\text{C}\)

Purity  
Clarity of solution—Dissolve 0.2 g of 4-dimethylaminocinnamaldehyde in 20 mL of ethanol (95): the solution is clear.

Loss on drying \(<2.41\%>: 0.5\%\) (1 g, 105°C, 2 hours).

Residue on ignition \(<2.44\%>: 0.1\%\) (1 g).

Nitrogen content \(<1.08\%>: 7.8 – 8.1\%\) (105°C, 2 hours, after drying).

\( p \)-Dimethylaminocinnamaldehyde TS  
See 4-dimethylaminocinnamaldehyde TS.

4-Dimethylaminocinnamaldehyde TS  
Before use, add 1 mL of acetic acid (100) to 10 mL of a solution of 4-dimethylaminocinnamaldehyde in ethanol (95) (1 in 2000).

Dimethylaminophenol  
\( (CH_3)_2NC_6H_4OH \) Dark purple, crystals or crystalline mass.

Melting point \(<2.60\%>: 85^\circ\text{C}\)

Dimethylamine  
See \( N,N \)-dimethylamine.

\( N,N \)-Dimethylamine  
\( C_9H_{12}N(CH_3)_2 \) Colorless or light yellow liquid, having a characteristic odor.

Specific gravity \(<2.56> d^2_20: 0.955 – 0.960\)

Distilling range \(<2.57\>: 192 – 195^\circ\text{C}, not less than 95 vol\%.

Dimethylformamide  
See \( N,N \)-dimethylformamide.

\( N,N \)-Dimethylformamide  
\( \text{HCON(CH}_3\text{)}_2 \) [K 8500, Special class]  
Read absorbance as directed under Ultraviolet-visible Spectrophotometry \(<2.24>\) (in a 1-cm cell, using water as the blank): the absorbance is not more than 0.60 at 270 nm, not more than 0.15 at 280 nm, and not more than 0.05 at 300 nm.

Dimethylglyoxime  
\( C_9H_{12}O_2 \) [K 8498, Special class]

Dimethylglyoxime-thiosemicarbazide TS  
Solution A: Dissolve 0.5 g of dimethylglyoxime in hydrochloric acid to make 100 mL. Prepare before use. Solution B: Dissolve 0.1 g of thiosemicarbazide in 50 mL of water with the acid of warming if necessary, and add diluted hydrochloric acid (1 in 2) to make 100 mL. Prepare before use.

Mix 10 mL of each solution A and solution B, add diluted hydrochloric acid (1 in 2) to make 100 mL, and allow the mixture to stand for 1 hour. Use within 24 hours.

Dimethylglyoxime TS  
Dissolve 1 g of dimethylglyoxime in ethanol (95) to make 100 mL.

Dimethyl malonate  
\( C_9H_{12}O_2 \) Clear, colorless or pale yellow liquid.

Specific gravity \(<2.48\%>: 1.152 – 1.162\)

Water \(<2.48\%>: 0.3\%\).

Residue on ignition \(<2.44\%>: 0.1\%\).

\( N,N \)-Dimethyl-n-octylamine  
\( C_{11}H_{24}N \) Colorless liquid.

Refractive index \(<2.45\%>: n^D_20: 1.424\)

\( N,N \)-Dimethyl-p-phenylenediammonium dichloride  
\( C_{12}H_{14}N_2Cl_2 \) [K 8193, \( N,N \)-Dimethyl-p-phenylenediammonium dichloride, Special class]

\( N,N \)-Dimethyl-p-phenylenediammonium hydrochloride  
See \( N,N \)-dimethyl-p-phenylenediamine dichloride.

Dimethyl phthalate  
\( C_9H_{10}O_4 \) Colorless, clear liquid, having a slight aroma.

Refractive index \(<2.45\%>: n^D_20: 1.491 – 1.493\)

Purity—To 6.0 mL of a solution of Dimethyl phthalate in isooctane (1 in 100) add a solution of n-amyl alcohol in hexane (3 in 1000) to make 50 mL, and perform the test with 10 mL of this solution as directed under Liquid Chromatography \(<2.01\>\) according to the conditions described in the Assay under Ergocalciferol or Cholecalciferol: any peak other than the principal peak does not appear.

Dimethylsulfoxide  
\( (CH_3)_2SO \) [K 9702, Special class]

Dimethylsulfoxide for ultraviolet-visible spectrophotometry  
\( (CH_3)_2SO \) Colorless crystals or clear colorless liquid, having a characteristic odor. It is highly hygroscopic.

Congealing point \(<2.42\>\): not less than 18.3°C.

Purity—Read absorbance of dimethylsulfoxide for ultra-
violet-visible spectrophotometry, immediately after saturating with nitrogen, using water as the blank as directed under Ultraviolet-visible Spectrophotometry \(2.26\); its value is not more than 0.20 at 270 nm, not more than 0.09 at 275 nm, not more than 0.06 at 280 nm, and not more than 0.015 at 300 nm. It exhibits no characteristic absorption between 260 nm and 350 nm.

\(\text{Water } < 2.45; \text{ not more than 0.1\%}.\)

2,6-Dimethyl-4(2-nitrosoaryl)3,5-pyridinedicarboxylic acid dimethyl ester for thin-layer chromatography

\(\text{C}_{17}\text{H}_{17}\text{O}_{4}\) Irradiate xenon light at 50,000 lx of illumination for 8 hours to a methanol solution of nifedipine (1 in 100), and evaporate the methanol on a water bath. Recrystallize the residue 4 times from 1-propanol, and dry in a desiccator (in vacuum, phosphorus pentoxide). Pale blue crystals. Very soluble in chloroform, freely soluble in acetone, and practically insoluble in water.

\(\text{Melting point } < 2.60; 93 - 95^\circ\text{C}\)

Content: not less than 99.0%. Assay—Weigh accurately about 0.4 g of 2,6-dimethyl-4(2-nitrosoaryl)-3,5-pyridinedicarboxylic acid dimethyl ester for thin-layer chromatography, dissolve in 70 mL of acetic acid (100), and titrate with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L perchloric acid VS = 32.83 mg of \(\text{C}_{17}\text{H}_{17}\text{O}_{4}\).

3-(4,5-Dimethylthiazole-2-yl)-2,5-diphenyl-2H-tetrazolium bromide \(\text{C}_{16}\text{H}_{16}\text{BrN}_{5}\) Yellow crystals. Melting point: about 195\(^\circ\text{C}\) (with decomposition).

3-(4,5-Dimethylthiazole-2-yl)-2,5-diphenyl-2H-tetrazolium bromide TS Dissolve 5 g of 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyl-2H-tetrazolium bromide in phosphate-buffered sodium chloride TS to make 1000 mL.

Dimorpholamine for assay [Same as the monograph Dimorpholamine. When dried, it contains not less than 99.0% of dimorpholamine (\(\text{C}_{20}\text{H}_{38}\text{N}_{4}\text{O}_{4}\)).

\(\text{m-Dinitrobenezene } \text{See 1,3-dinitrobenezene.}\)

1,2-Dinitrobenezene \(\text{C}_{6}\text{H}_{4}(\text{NO}_{2})_{2}\) Occurs as yellowish white to brownish yellow crystals or a crystalline powder.

Identification—Determine the infrared absorption spectrum of 1,2-dinitrobenezene as directed in the paste method under Infrared Spectrophotometry \(2.25\); it exhibits absorption at the wave numbers of about 3100 cm\(^{-1}\), 1585 cm\(^{-1}\), 1526 cm\(^{-1}\), 1352 cm\(^{-1}\), and 793 cm\(^{-1}\).

\(\text{Melting point } < 2.60; 116 - 119^\circ\text{C}\)

1,3-Dinitrobenezene \(\text{C}_{6}\text{H}_{5}(\text{NO}_{2})_{2}\) Light yellow to reddish-yellow crystals or crystalline powder.

\(\text{Melting point } < 2.60; 88 - 92^\circ\text{C}\).

Preserve in a light-resistant tight container.

\(\text{m-Dinitrobenezene TS } \text{See 1,3-dinitrobenezene TS.}\)

1,3-Dinitrobenezene TS Dissolve 1 g of 1,3-dinitrobenezene in 100 mL of ethanol (95%). Prepare before use.

\(\text{m-Dinitrobenezene TS, alkaline } \text{See 1,3-dinitrobenezene TS, alkaline.}\)

1,3-Dinitrobenezene TS, alkaline Mix 1 mL of tetramethylammonium hydroxide and 140 mL of ethanol (99.5), titrate a part of the mixture with 0.01 mol/L hydrochloric acid VS, and dilute the remainder with ethanol (99.5) to give a 0.008 mol/L solution. Before use, mix 40 mL of this solution with 60 mL of a solution of 1,3-dinitrobenezene in benzene (1 in 20).

2,4-Dinitrochlorobenezene See 1-chloro-2, 4-dinitrobenzene.

2,4-Dinitrofluorobenzene See 1-fluoro-2, 4-dinitrobenzene.

2,4-Dinitrophenol \(\text{C}_{6}\text{H}_{4}\text{OH(NO}_{2})_{2}\) Yellow crystals or crystalline powder.

\(\text{Melting point } < 2.60; 110 - 114^\circ\text{C}\)

2,4-Dinitrophenol TS Dissolve 0.5 g of 2,4-dinitrophenol in 100 mL of ethanol (95).

2,4-Dinitrophenylhydrazine \((\text{NO}_{2})_{2}\text{C}_{6}\text{H}_{3}\text{NHNH}_{2}\) [K 8460, Special class]

2,4-Dinitrophenylhydrazine-diethylene glycol dimethyl ether TS Dissolve 3 g of 2,4-dinitrophenylhydrazine in 100 mL of diethylene glycol dimethyl ether while heating, cool, and filter if necessary.

2,4-Dinitrophenylhydrazine-ethanol TS Dissolve 1.5 g of 2,4-dinitrophenylhydrazine in a cold mixture of 10 mL of sulfuric acid and 10 mL of water, then add a mixture of 1 volume of aldehyde-free ethanol and 3 volumes of water to make 100 mL, and filter if necessary.

2,4-Dinitrophenylhydrazine TS Dissolve 1.5 g of 2,4-dinitrophenylhydrazine in a cold mixture of 10 mL of sulfuric acid and 10 mL of water, then add water to make 100 mL, and filter if necessary.

Dinonyl phthalate \(\text{C}_{20}\text{H}_{38}\text{O}_{4}\) Colorless to pale yellow, clear liquid.

\(\text{Specific gravity } < 2.50; 0.967 - 0.987\)

\(\text{Acid value } < 1.13\); not more than 2.

Dioxane See 1,4-dioxane.

1,4-Dioxane \(\text{C}_{4}\text{H}_{8}\text{O}_{2}\) [K 8461, Special class]

Diphenhydramine \(\text{C}_{17}\text{H}_{19}\text{NO}\) [Same as the namesake monograph]

Diphenhydramine tannate [Same as the namesake monograph]

Diphenyl \(\text{C}_{12}\text{H}_{10}\) White crystals or crystalline powder, having a characteristic odor. Freely soluble in acetone and in diethyl ether, soluble in ethanol (95), and practically insoluble in water.

\(\text{Melting point } < 2.60; 68 - 72^\circ\text{C}\)

\(\text{Purity} \text{—Dissolve } 0.1 \text{ g of diphenyl in } 5 \text{ mL of acetone and use this solution as the sample solution. Perform the test with } 2 \mu\text{L of this solution as directed under Gas Chromatography } <2.02> \text{ according to the following conditions. Measure each peak area by the automatic integration method and calculate the amount of diphenyl by the area percentage method; it shows the purity of not less than 98.0\%.}\)

Operating conditions

Detector: Hydrogen flame-ionization detector.

Column: A glass tube about 3 mm in inside diameter and about 2 m in length, packed with 150 to 180 \(\mu\text{m}\) mesh siliceous earth for gas chromatography coated with 10\% of
polyethylene glycol 20 M for thin-layer chromatography.

Column temperature: A constant temperature of about 180°C.

Carrier gas: Nitrogen.

Flow rate: Adjust the flow rate so that the retention time of diphenyl is about 8 minutes.

Detection sensitivity: Adjust the detection sensitivity so that the peak height of diphenyl obtained from 2 μL of the solution prepared by adding acetone to 1.0 mL of the sample solution to make 100 mL is 5% to 15% of the full scale.

Time span of measurement: About 3 times as long as the retention time of diphenyl beginning after the solvent peak.

Diphenylamine (C₆H₅)₂NH [K 8487, Special class]

Diphenylamine-acetic acid TS Dissolve 1.5 g of diphenylamine in 1.5 mL of sulfuric acid and acetic acid (100) to make 100 mL.

Diphenylamine-acetic acid (100) TS See diphenylamine-acetic acid TS.

Diphenylamine TS Dissolve 1 g of diphenylamine in 100 mL of sulfuric acid. Use the colorless solution.

9,10-Diphenylanthracene C₂₆H₁₈ Yellow crystalline powder. Soluble in diethyl ether, and practically insoluble in water.

Melting point <2.60°: about 248°C

1,4-Diphenylbenzene C₂₆H₂₀ White scaly crystals, having a slight aromatic odor. It is freely soluble in ethanol (99.5), and slightly soluble in water.

Identification—Determine the infrared absorption spectrum of 1,4-diphenylbenzene as directed in the potassium bromide disk method as di-bromide disk method under Infrared Spectrophotometry 〈2,25〉: it exhibits absorption at the wave numbers of about 3050 cm⁻¹, 3030 cm⁻¹, 2960 cm⁻¹, 1449 cm⁻¹, 1302 cm⁻¹, 1267 cm⁻¹, 1124 cm⁻¹, 995 cm⁻¹, 834 cm⁻¹, 740 cm⁻¹ and 680 cm⁻¹.

Diphenylcarbazide See 1,5-diphenylcarbonohydrazide.

Diphenylcarbazide TS See 1,5-diphenylcarbonohydrazide TS.

Diphenylcarbazone C₁₈H₁₄N₂O [K 8488, Special class]

1,5-Diphenylcarbonohydrazide C₁₃H₁₄N₄O [K 8487, Special class]

1,5-Diphenylcarbonohydrazide TS Dissolve 0.2 g of 1,5-diphenylcarbonohydrazide in 100 mL of a mixture of ethanol (95) and acetic acid (100) (9:1).

5% Diphenyl-95% dimethylpolysiloxane for gas chromatography Prepared for gas chromatography.

Diphenyl ether C₆H₄O Colorless crystals, having a geranium-like aroma. Dissolves in alcohol (95) and in diethyl ether, and practically insoluble in water.

Specific gravity <2.56> d₄° = 1.072 – 1.075

Boiling point <2.57>: 254 – 259°C

Melting point <2.60°>: 28°C

Diphenyl imidazole C₆H₅N₂ White crystals or crystaline powder, freely soluble in acetic acid (100), and sparingly soluble in methanol.

Melting point <2.60°>: 234 – 238°C

Loss on drying <2.41>: not more than 0.5% (0.5 g, 105°C, 3 hours).

Content: not less than 99.0%. Assay—Dissolve about 0.3 g of diphenyl imidazole, previously dried and weighed accurately, in 70 mL of acetic acid (100), and titrate <2.50> with 0.1 mol/L perchloric acid VS (indicator: 2 drops of crystal violet TS).

Each mL of 0.1 mol/L perchloric acid VS = 22.03 mg of C₆H₅N₂

Diphenyl phthalate C₄H₆(COOC₆H₅)₂ White crystalline powder.

Melting point <2.60°>: 71 – 76°C

Purity Related substances—Dissolve 60 mg of diphenyl phthalate in 50 mL of chloroform and use this solution as the sample solution. Proceed with 10 μL of the sample solution as directed in the Assay under Tolnaftate Solution: any peak other than the principal peak at the retention time of about 8 minutes and the peak of the solvent does not appear. Adjust the detection sensitivity so that the peak height of diphenyl phthalate obtained from 10 μL of the sample solution is 50 to 100% of the full scale, and the time span of measurement is about twice as long as the retention time of diphenyl phthalate after the solvent peak.

1,1-Diphenyl-4-pyridinino-1-butene hydrochloride for thin-layer chromatography C₂₁H₂₅N.HCl To 1 g of diphenidole hydrochloride add 30 mL of 1 mol/L hydrochloric acid TS, and heat under a reflux condenser for 1 hour. After cooling, extract twice with 30 mL-portions of chloroform, combine the chloroform extracts, wash twice with 10 mL portions of water, and evaporate chloroform under reduced pressure. Recrystallize the residue from a mixture of diethyl ether and ethanol (95) (3:1), and dry in a desiccator (in vacuum, silica gel) for 2 hours. White crystals or crystalline powder.

Absorbance <2.24> E₅₅₆ cm⁻¹ (250 nm): 386 – 446 (10 mg, water, 1000 mL).

Melting point <2.60°>: 176 – 180°C

Content: not less than 99.0%. Assay—Dissolve about 0.2 g of 1,1-diphenyl-4-pyridinino-1-butene hydrochloride for thin-layer chromatography, previously weighed accurately, in 20 mL of acetic acid (100), add 20 mL of acetic anhydride, and titrate <2.50> with 0.05 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.05 mol/L perchloric acid VS = 16.39 mg of C₂₁H₂₅N.HCl

Dipicolinic acid C₆H₅NO₂ White powder.

Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry 〈2.25〉: it exhibits absorption at the wave numbers of about 2630 cm⁻¹, 1701 cm⁻¹, 1576 cm⁻¹, 1416 cm⁻¹, 1300 cm⁻¹ and 1267 cm⁻¹.
Purity: Clarity and color of solution—Dissolve by warming 0.5 g in 20 mL of ethanol (99.5), and cool; a clear, colorless liquid.

Content: Not less than 98.0%. Assay—Weigh accurately about 0.1 g, add 25 mL of ethanol (99.5), dissolve by warming, cool, then titrate with 0.1 mol/L sodium hydroxide VS (indicator: 2 drops of phenolphthalein TS). Perform a blank determination in the same manner and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 8.356 mg of C₈H₇O₄N

Dipotassium hydrogen phosphate K₂HPO₄ [K 9017, Special class]

Disodium hydrogen phosphate-citric acid buffer solution, pH 5.3 Mix 100 mL of 1 mol/L dipotassium hydrogen phosphate TS for buffer solution and 38 mL of 1 mol/L citric acid TS for buffer solution, and add water to make 200 mL.

1 mol/L Disodium hydrogen phosphate TS for buffer solution Dissolve 174.18 g of diopotassium hydrogen phosphate in water to make 1000 mL.

Diprophyline C₆H₅N₂O₂ A white, powder or grain. Freely soluble in water, and slightly soluble in ethanol (95).

Identification—Determine the infrared absorption spectrum of the substance to be examined, previously dried at 105°C for 4 hours, as directed in the potassium bromide disk method under Infrared Spectrophotometry (<2.25): it exhibits absorption at the wave numbers of about 3460 cm⁻¹, 3330 cm⁻¹, 1651 cm⁻¹, 1242 cm⁻¹, 1059 cm⁻¹, and 1035 cm⁻¹.

α,α'-Dipyridyl See 2,2'-bipyridyl.

Disodium chloromotropate dihydrate C₁₀H₁₄N₄O₄ [K 8316, Special class] Preserve in light-resistant containers.

Disodium hydrogen ethylenediamine tetaacetate dihydrate C₁₀H₁₂N₂Na₂O₈.2H₂O [K 9020, Special class]

0.1 mol/L Disodium hydrogen ethylenediamine tetaacetate TS Dissolve 37.2 g of disodium hydrogen ethylenediamine tetraacetate dihydrate in water to make 1000 mL.

0.04 mol/L Disodium hydrogen ethylenediamine tetaacetate TS Dissolve 14.890 g of disodium hydrogen ethylenediamine tetraacetate dihydrate in water to make 1000 mL.

0.4 mol/L Disodium hydrogen ethylenediamine tetaacetate TS, pH 8.5 Dissolve 148.9 g of disodium hydrogen ethylenediamine tetraacetate dihydrate in about 800 mL of water, adjust to pH 8.5 with 8 mol/L sodium hydroxide TS, and add water to make 1000 mL.

Disodium ethylenediaminetetraacetate See disodium hydrogen ethylenediamine tetraacetate dihydrate.

Disodium ethylenediaminetetraacetate copper See copper (II) disodium ethylenediamine tetraacetate tetrahydrate.

0.1 mol/L Disodium ethylenediaminetetraacetate TS See 0.1 mol/L disodium hydrogen ethylenediamine tetaacetate TS.

Disodium hydrogen phosphate, anhydrous Na₂HPO₄ [K 9020, Special class]

Disodium hydrogen phosphate-citric acid buffer solution, pH 3.0 Dissolve 35.8 g of disodium hydrogen phosphate dodecahydrate in water to make 500 mL. To this solution add a solution of citric acid monohydrate (21 in 1000) to adjust the pH to 3.0.

Disodium hydrogen phosphate-citric acid buffer solution, pH 4.5 Dissolve 21.02 g of citric acid monohydrate in water to make 1000 mL, and adjust the pH to 4.5 with a solution prepared by dissolving 35.82 g of disodium hydrogen phosphate 12-water in water to make 1000 mL.

Disodium hydrogen phosphate-citric acid buffer solution, pH 5.0 Dissolve 7.1 g of anhydrous disodium hydrogen phosphate in water to make 1000 mL, and adjust to pH 5.0 with a solution prepared by dissolving 5.25 g of citric acid monohydrate in water to make 1000 mL.

Disodium hydrogen phosphate-citric acid buffer solution, pH 5.4 Dissolve 1.05 g of citric acid monohydrate and 2.92 g of disodium hydrogen phosphate dodecahydrate in 200 mL of water, and adjust the pH with phosphoric acid or sodium hydroxide TS, if necessary.

Disodium hydrogen phosphate-citric acid buffer solution, pH 6.0 Dissolve 71.6 g of disodium hydrogen phosphate dodecahydrate in water to make 1000 mL. To this solution add a solution, prepared by dissolving 21.0 g of citric acid monohydrate in water to make 1000 mL, until the pH becomes 6.0 (ratio of volume: about 63:37).

Disodium hydrogen phosphate-citric acid buffer solution, pH 6.0 To 1000 mL of 0.05 mol/L disodium hydrogen phosphate TS add a solution prepared by dissolving 5.25 g of citric acid monohydrate in water to make 1000 mL to adjust pH 6.0.

Disodium hydrogen phosphate-citric acid buffer solution, pH 7.2 Dissolve 7.1 g of disodium hydrogen phosphate in water to make 1000 mL. Adjust this solution to pH 7.2 with a solution prepared by dissolving 5.3 g of citric acid monohydrate in water to make 1000 mL.

Disodium hydrogen phosphate-citric acid buffer solution, pH 7.5 Dissolve 5.25 g of citric acid monohydrate in water to make 1000 mL. Add this solution to 1000 mL of 0.05 mol/L disodium hydrogen phosphate TS to adjust the pH to 7.5.

Disodium hydrogen phosphate-citric acid buffer solution for penicillium origin β-galactosidase, pH 4.5 Dissolve 71.6 g of disodium hydrogen phosphate dodecahydrate in water to make 1000 mL, and adjust the pH to 4.5 with a solution prepared by dissolving 21.0 g of citric acid monohydrate in water to make 1000 mL (volume ratio: about 44:56).

Disodium hydrogen phosphate dodecahydrate Na₂HPO₄.12H₂O [K 9019, Special class]

Disodium hydrogen phosphate for pH determination Na₂HPO₄ [K 9020, for pH determination]

Disodium hydrogen phosphate TS Dissolve 12 g of disodium hydrogen phosphate dodecahydrate in water to make 100 mL (0.3 mol/L).
0.05 mol/L Disodium hydrogen phosphate TS Dissolve 7.0982 g of disodium hydrogen phosphate in water to make 1000 mL.

0.5 mol/L Disodium hydrogen phosphate TS Dissolve 70.982 g of disodium hydrogen phosphate in water to make 1000 mL.

Disodium 1-nitroso-2-naphthol-3,6-disulfonate

C_{10}H_{5}NNa_{2}O_{8}S_{2} Yellow crystals or crystalline powder. Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method as directed under Infrared Spectrophotometry 2.255: it exhibits absorption at the wave numbers of about 3400 cm\(^{-1}\), 1639 cm\(^{-1}\), 1451 cm\(^{-1}\), 1270 cm\(^{-1}\), 1231 cm\(^{-1}\), 1173 cm\(^{-1}\), 1049 cm\(^{-1}\), 848 cm\(^{-1}\) and 662 cm\(^{-1}\).

Preserve in a light-resistant tight container.

Dissolved acetylene C_{2}H_{2} [K 1902]

Distigmine bromide for assay C_{22}H_{32}Br_{2}N_{4}O_{4} [Same as the monograph Distigmine Bromide. It contains not less than 99.0% of distigmine bromide (C_{22}H_{32}Br_{2}N_{4}O_{4}), calculated on the anhydrous basis.]

Distilled water for injection [Use the water prescribed by the monographs of Water for Injection or Sterile Water for Injection in Containers. Prepared by distillation. It is not necessary to check the conformity to all the specification items of the monograph, if it is confirmed that the water to be used is suitable for the purpose of relevant test.]

2,6-Di-tert-butylcresol [(CH\(_{3}\))\(_{2}\)C\(_{6}\)H\(_{4}\)(CH\(_{3}\))OH A white, crystalline powder. Freely soluble in ethanol (95). Melting point 2.60: 69 - 71°C

Residue on ignition 2.44: not more than 0.05%.

2,6-Di-tert-butylcresol TS Dissolve 0.1 g of 2,6-di-tert-butylcresol in ethanol (95) to make 10 mL.

2,6-Di-tert-butyl-p-cresol See 2,6-di-tert-butylicresol.

2,6-Di-tert-butyl-p-cresol TS See 2,6-di-tert-butylcresol TS.

1,3-Di (4-pyridyl) propane C\(_{10}\)H\(_{14}\)N\(_{2}\) A pale yellow powder.

Melting point 2.60: 61 - 62°C

Water 2.48: less than 0.1%.

1,1'-[3,3'-Dithiobis(2-methyl-1-oxopropyl)]-1-diproline C\(_{18}\)H\(_{28}\)N\(_{2}\)O\(_{2}\)S\(_{2}\) White, crystals or crystalline powder. Sparingly soluble in methanol, and practically insoluble in water. Identification—Determine the infrared absorption spectrum of 1,1'-[3,3'-dithiobis(2-methyl-1-oxopropyl)]-1-diproline according to potassium bromide disk method under Infrared Spectrophotometry 2.255: it exhibits absorption at the wave numbers of about 2960 cm\(^{-1}\), 1750 cm\(^{-1}\), 1720 cm\(^{-1}\), 1600 cm\(^{-1}\), 1480 cm\(^{-1}\), 1450 cm\(^{-1}\) and 1185 cm\(^{-1}\).

Purity Related substances—Dissolve 0.10 g of 1,1'-[3,3'-dithiobis(2-methyl-1-oxopropyl)]-1-diproline in exactly 10 mL of methanol. Perform the test with this solution as directed in the Purity (3) under Captopril: any spot other than the principal spot at the RF value of about 0.2 does not appear.

Content: not less than 99.0%. Assay—Weigh accurately about 0.3 g of 1,1'-[3,3'-dithiobis(2-methyl-1-oxopropyl)]-1-diproline, dissolve in 20 mL of methanol, add 50 mL of water, and titrate 2.50 with 0.1 mol/L sodium hydroxide VS until the color of the solution changes from yellow through bluish green to blue (indicator: 3 drops of bromothymol blue TS). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 21.63 mg of C\(_{22}\)H\(_{32}\)N\(_{2}\)O\(_{4}\)

Dithiodiglycolic acid C\(_{4}\)H\(_{6}\)O\(_{2}\)S Prepared for amino acid analysis or biochemistry.

Dithiodipropionic acid C\(_{4}\)H\(_{8}\)O\(_{2}\) Prepared for amino acid analysis or biochemistry.

Dithiothreitol C\(_{4}\)H\(_{6}\)O\(_{2}\)S Crystals.

Melting point 2.60: about 42°C

Dithizone C\(_{4}\)H\(_{9}\)NHNHC\(_{6}\)N\(_{2}\)H\(_{2}\) [K 8490, Special class]

Dithizone solution for extraction Dissolve 30 mg of dithizone in 1000 mL of chloroform, and add 5 mL of ethanol (95). Store in a cold place. Before use, shake a suitable volume of the solution with one-half of its volume of diluted nitric acid (1 in 100), and use the chloroform layer after discarding the water layer.

Dithizone TS Dissolve 25 mg of dithizone in ethanol (95) to make 100 mL. Prepare before use.

Dopamine hydrochloride for assay C\(_{9}\)H\(_{11}\)NO\(_{2}\)HCl [Same as the monograph Dopamine hydrochloride. When dried, it contains not less than 99.0% of dopamine hydrochloride (C\(_{9}\)H\(_{11}\)NO\(_{2}\)HCl)].

Doxifluridine C\(_{8}\)H\(_{11}\)FN\(_{2}\)O\(_{3}\) [Same as the namesake monograph]

Doxifluridine for assay C\(_{8}\)H\(_{11}\)FN\(_{2}\)O\(_{3}\) [Same as the monograph Doxifluridine. When dried, it contains not less than 99.5% of dioxifluridine (C\(_{8}\)H\(_{11}\)FN\(_{2}\)O\(_{3}\)).]

Dragendorff’s TS Dissolve 0.85 g of bismuth subnitrate in 10 mL of acetic acid (100) and 40 mL of water with vigorous shaking (solution A). Dissolve 8 g of potassium iodide in 20 mL of water (solution B). Immediately before use, mix equal volumes of solution A, solution B and acetic acid (100). Store solution A and solution B in light-resistant containers.

Dragendorff’s TS for spraying Add 20 mL of diluted acetic acid (31) (1 in 5) to 4 mL of a mixture of equal volumes of solution A and solution B of Dragendorff’s TS. Prepare before use.

Dried human normal plasma powder Freeze-dried normal plasma obtained from healthy human.

Dried sodium carbonate Na\(_{2}\)CO\(_{3}\) [Same as the namesake monograph]

Droxidopa for assay C\(_{9}\)H\(_{12}\)NO\(_{3}\) [Same as the monograph Droxidopa. When dried, it contains not less than 99.5% of droxidopa (C\(_{9}\)H\(_{12}\)NO\(_{3}\)).]

Dydrogesterone for assay C\(_{21}\)H\(_{28}\)O\(_{2}\) [Same as the monograph Dydrogesterone. When dried, it contains not less than 99.5% of C\(_{21}\)H\(_{28}\)O\(_{2}\)].

Ebastine for assay C\(_{32}\)H\(_{39}\)NO\(_{2}\) [Same as the monograph

---

**JP XVI**

**General Tests / 9.41 Reagents, Test Solutions 221**
Ebastine. When dried, it contains not less than 99.5% of ebastine (C₂₂H₂₉NO₅).

Ebacet sodium hydrate for assay C₂₀H₂₇NaO₅S.5H₂O
[Same as the monograph Ebacet Sodium Hydrate. It contains not less than 99.5% of ebacet sodium (C₂₀H₂₇NaO₅S), calculated on the anhydrous basis.]

E. coli protein Process E. coli cells (E. coli N4830/pTB281) retaining a plasmid deficient in the celmoleukin gene according to the celmoleukin purification process in the following order; (i) extraction, (ii) butylated vinyl polymer hydrophobic chromatography, (iii) carboxymethylated vinyl polymer ion-exchange column chromatography, and (iv) sulfopropyl-polymer ion-exchange chromatography, and during process (iv) collect the fractions corresponding to the celmoleukin elution position. Dialyze the fractions obtained in (iv) against 0.01 mol/L acetate buffer solution, pH 5.0, and take the dialysis solution as E. coli protein.

Identification—Clear and colorless solution.

Protein content: When determining the protein content using the Assay (I) Total protein content under Celmoleukin (Genetical Recombination), the protein content per mL is 0.1 to 0.5 mg.

E. coli protein stock solution A solution obtained by culturing a bacteria that contains a plasmid lacking the teceleukin gene but is otherwise exactly identical to the teceleukin-producing E. coli strain in every function except teceleukin production, and then purified using a purification technique that is more simple than that for teceleukin. Determine the amount of protein by Brodford method using bovine serum albumin as the standard substance. Store shielded from light at -70°C.

Eleutherose B for liquid chromatography C₁₇H₂₀O₄.H₂O A white crystalline powder. Sparingly soluble in methanol, slightly soluble in water, and very slightly soluble in ethanol (99.5). Melting point: 190 – 194°C.

Identification—Determine the absorption spectrum of a solution in methanol (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>; it exhibits a maximum between 261 nm and 265 nm.

Purity Related substances—Dissolve 1.0 mg in 10 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak area by the automatic integration method: the total area of peaks other than emetine from the sample solution is not larger than the peak of emetine from the standard solution (1).

Operating conditions
Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Identification under Eleutherococcus Senticosus Rhizome.

Time span of measurement: About 3 times as long as the retention time of eleutherose B beginning after the solvent peak.

System suitability
Test for required detectability: To exactly 1 mL of the standard solution add methanol to make exactly 20 mL. Confirm that the peak area of eleutherose B obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.

System performance: Proceed as directed in the system suitability in the Identification under Eleutherococcus Senticosus Rhizome.

EMB plate medium Melt eosin methylene blue agar medium by heating, and cool to about 50°C. Transfer about 20 mL of this medium to a Petri dish, and solidify horizontally. Place the dish with the cover slightly opened in the incubator to evaporate the inner vapor and water on the plate.

Emetine hydrochloride for assay C₂₉H₂₁N₂O₄.2HCl.xH₂O A white or light-yellow crystalline powder. Soluble in water.

Melting point <2.60>; about 250°C [with decomposition, after drying in a desiccator (reduced pressure below 0.67 kPa, phosphorus (V) oxide, 50°C) for 5 hours].

Absorbance <2.24> E₁cm(283 nm): 116 – 127 (10 mg, diluted methanol (1 in 2), 400 mL) [after drying in a desiccator (reduced pressure below 0.67 kPa, phosphorus (V) oxide, 50°C) for 5 hours.]

Purity Related substances—Dissolve 10 mg of emetine hydrochloride for assay in 10 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 10 μL each of the sample solution and standard solution (1) as directed under Liquid Chromatography <2.01> according to the following operating conditions. Determine the peak areas from both solutions by the automatic integration method: the total area of peaks other than emetine from the sample solution is not larger than the peak of emetine from the standard solution (1).

Operating conditions
Proceed the operating conditions in the Assay under Ipecac except the detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add the mobile phase to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the sensitivity so that the peak area of emetine obtained from 10 μL of the standard solution (2) can be measured by the automatic integration method, and the peak height of emetine obtained from 10 μL of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About 3 times as long as the retention time of emetine beginning after the solvent peak.

Emetine for component determination See emetine for assay.

Emorfonyl for assay C₁₁H₁₅N₃O₃ [Same as the monograph Emorfonyl. When dried, it contains not less than 99.0% of emorfonyl (C₁₁H₁₅N₃O₃).]

Enalapril maleate C₂₀H₂₉N₂O₄,C₆H₄O₄ [Same as the namesake monograph]
dium by heating in a water bath, and adjust the pH to between 7.5 and 7.8. Add 10 g of lactose monohydrate previously dissolved in a small quantity of water, mix thoroughly, and add 1 mL of fuchsin-ethanol (95 TS). After cooling to about 50°C, add dropwise a freshly prepared solution of sodium bisulfite (1 in 10) until a light red color develops owing to reducing fuchsin, requiring about 10 to 15 mL of a solution of sodium sulfite heptahydrate (1 in 10). Dispense the mixture, and sterilize fractionally on each of three successive days for 15 minutes at 100°C.

**Endo’s plate medium** Melt Endo’s medium by heating, and cool to about 50°C. Transfer about 20 mL of this medium to a Petri dish, and solidify horizontally. Place the dishes with the cover slightly opened in the incubator to evaporate the inner vapor and water on the surface of the agar.

**Enflurane** C₇H₆ClF₂O [Same as the namesake monograph]

**Enzyme TS** The supernatant liquid is obtained as follows: To 0.3 g of an enzyme preparation potent in amylolytic and phosphorolytic activities, obtained from Aspergillus oryzae, add 10 mL of water and 0.5 mL of 0.1 mol/L hydrochloric acid TS, mix vigorously for a few minutes, and centrifuge. Prepare before use.

**Eosin** See eosin Y.

**Eosin Y** C₉H₈Br₃Na₂O₅ Red, masses or powder.

**Identification**—To 10 mL of a solution (1 in 1000) add 1 drop of hydrochloric acid: yellow-red precipitates appear.

**Eosin methyl blue agar medium** Dissolve by boiling 10 g of casein peptone, 2 g of dipotassium hydrogenphosphate and 25 to 30 g of agar in about 900 mL of water. To this mixture add 10 g of lactose monohydrate, 20 mL of a solution of eosin Y (1 in 50), 13 mL of a solution of sodium bisulfite (1 in 10) until a light red color develops owing to reducing fuchsin, requiring about 10 to 15 mL of a solution of sodium sulfite heptahydrate (1 in 10). Dispense the mixture, and sterilize fractionally on each of three successive days for 15 minutes at 100°C.

**Ephedrine hydrochloride** C₁₀H₁₅NO.HCl [Same as the namesake monograph]

**Ephedrine hydrochloride for assay** See ephedrine hydrochloride.

**6-Epideoxytetracycline hydrochloride** C₂₀H₂₁NO₇.HCl Yellow to dark yellow, crystals or crystalline powder.

**Purity** Related substances—Dissolve 20 mg of 6-epideoxytetracycline hydrochloride in 25 mL of 0.01 mol/L hydrochloric acid TS, and use this solution as the sample solution. Proceed the test with 20 μL of the sample solution as directed in the Purity (2) under Oxytetracycline Hydrochloride, determine each peak area by the automatic integration method, and calculate the amounts of them by the area percentage method: the total amount of the peaks other than 4-epoxytetracycline is not more than 10%.

**Eriochrome black T** C₉H₁₂N₃NaO₆S [K 8736, Special class]

**Eriochrome black T-sodium chloride indicator** Mix 0.1 g of eriochrome black T and 10 g of sodium chloride, and triturate until the mixture becomes homogeneous.

**Eriochrome black T TS** Dissolve 0.3 g of eriochrome black T and 2 g of hydroxyamphetamine chloride in methanol to make 50 mL. Use within 1 week. Preserve in light-resistant containers.

**Erythromycin B** C₃₇H₆₇NO₁₂ White to light yellowish white powder.

**Purity** Related substances—Dissolve 10 mg of erythromycin B in 1 mL of methanol, add a mixture of phosphate buffer solution, pH 7.0 and methanol (15:1) to make 5 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add a mixture of phosphate buffer solution, pH 7.0 and methanol (15:1) to make exactly 20 mL, and use this solution as the standard solution. Proceed with exactly 100 μL each of the sample solution and standard solution as directed in the Purity (3) Related substances under Erythromycin, and determine each peak area from the solutions by the automatic integration method: the total of areas of the peaks other than erythromycin B from the sample solution is not more than the peak area of erythromycin B from the standard solution.

**Erythromycin C** C₃₆H₆₅NO₁₃ White to light yellowish white powder.

**Purity** Related substances—Dissolve 10 mg of erythromycin C in 1 mL of methanol, add a mixture of phosphate buffer solution, pH 7.0 and methanol (15:1) to make 5 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add a mixture of phosphate buffer solution, pH 7.0 and methanol (15:1) to make exactly 20 mL, and use this solution as the standard solution. Proceed with exactly 100 μL each of the sample solution and standard solution as directed in the Purity (3) Related substances under Erythromycin, and determine each peak area from the solutions by the automatic integration method: the total of areas of the peaks other than erythromycin C from the sample solution is not more than the peak area of erythromycin C from the standard solution.

**Essential oil** Same as the essential oil under the monograph.

**Etacrylic acid for assay** [Same as the monograph Etacrylic acid. When dried, it contains not less than 99.0% of etacrylic acid (C₁₂H₁₂Cl₂O₄)₃.]

**Ethanol** See ethanol (95).

**Ethanol, aldehyde-free** Transfer 1000 mL of ethanol (95) to a glass-stoppered bottle, add the solution prepared by dissolving 2.5 g of lead (II) acetate trihydrate in 5 mL of water, and mix thoroughly. In a separate container, dissolve 5 g of potassium hydroxide in 25 mL of warm ethanol (95), cool, and add this solution gently, without stirring, to the first so-
lution. After 1 hour, shake this mixture vigorously, allow to stand overnight, decant the supernatant liquid, and distil the ethanol.

**Ethanol, dehydrated** See ethanol (99.5).

**Ethanol, dilute** To 1 volume of ethanol (95) add 1 volume of water. It contains 47.45 to 50.00 vol% of C₂H₅OH.

**Ethanol, diluted** Prepare by diluting ethanol (99.5).

**Ethanol for alcohol number determination** See Alcohol Number Determination <1.01>.

**Ethanol for disinfection** [Same as the namesake monograph]

**Ethanol for gas chromatography** Use ethanol prepared by distilling ethanol (99.5) with iron (II) sulfate heptahydrate. Preserve in containers, in which the air has been displaced with nitrogen, in a dark, cold place.

**Ethanol-free chloroform** See chloroform, ethanol-free.

**Ethanol-isotonic sodium chloride solution** To 1 volume of ethanol (95) add 19 volumes of isotonic sodium chloride solution.

**Ethanol, methanol-free** See ethanol (95), methanol-free.

**Ethanol, neutralized** To a suitable quantity of ethanol (95) add 2 to 3 drops of phenolphthalein TS, then add 0.01 mol/L or 0.1 mol/L sodium hydroxide VS until a light red color develops. Prepare before use.

**Ethanol (95)** C₂H₅OH [K 8102, Special class]

**Ethenzamide** C₉H₁₁NO₂ [Same as the namesake monograph]

**Ether** See diethyl ether.

**Ether, anesthetic** C₆H₅OC₂H₅ [Same as the namesake monograph]

**Ether, dehydrated** See diethyl ether, dehydrated.

**Ether for purity of crude drug** See diethyl ether for purity of crude drug.

**Ethynylestradiol** C₂₀H₂₄O₂ [Same as the namesake monograph]

**3-Ethoxy-4-hydroxybenzaldehyde** C₉H₁₀O₃ White to pale yellowish white crystalline. Freely soluble in ethanol (95), and slightly soluble in water.

**Melting point** <2.60°: 76 – 78°C

**Content:** not less than 98.0%. Assay—Weigh accurately about 0.3 g of 3-ethoxy-4-hydroxybenzaldehyde, previously dried in a desiccator (phosphorous (V) oxide) for 4 hours, dissolve in 50 mL of N,N-dimethylacetamide, and titrate <2.50° with 0.1 mol/L sodium methoxide VS (indicator: thymol blue TS).

Each mL of 0.1 mol/L sodium methoxide VS = 16.62 mg of C₉H₁₀O₃

**p-Ethoxyphenol** See 4-ethoxyphenol.

**4-Ethoxyphenol** C₈H₁₀O₂ White to light yellow-brown crystals or crystalline powder. Freely soluble in ethanol (95), and very slightly soluble in water.

**Melting point** <2.60°: 62 – 68°C

**Purity**—Dissolve 0.5 g of 4-Ethoxyphenol in 5 mL of ethanol (95), and use this solution as the sample solution. Perform the test as directed under Gas Chromatography <2.02> according to the following conditions. Measure each peak area by the automatic integration method and calculate the amount of substance other than 4-ethoxyphenol by the area percentage method: it is not more than 2.0%.

**Operating conditions**

Detector: Thermal conductivity detector.

Column: A glass column about 3 mm in inside diameter and about 2 m in length, packed with 180- to 250-μm siliceous earth for gas chromatography coated with methyl-silicone polymer for gas chromatography.

Column temperature: A constant temperature of about 150°C.

Carrier gas: Herium.

Flow rate: Adjust the flow rate so that the retention time of 4-ethoxyphenol is about 5 minutes.

Detection sensitivity: Adjust the detection sensitivity so that the peak height of 4-ethoxyphenol obtained from 1 μL of the sample solution is not less than 50% of the full scale.

Time span of measurement: 3 times as long as the retention time of 4-ethoxyphenol beginning after the solvent peak.

**Ethyl acetate** CH₃COOC₂H₅ [K 8361, Special class]

**Ethyl aminobenzoate** C₉H₁₀O₂ [Same as the namesake monograph]

**Ethylbenzene** C₆H₅C₂H₅ A colorless liquid. Freely soluble in ethanol (99.5) and in acetone, and practically insoluble in water.

**Specific gravity** <2.56°: d₂₀°: 0.862 – 0.872

**Boiling point** <2.57°: about 135°C

**Ethyl benzoate** C₆H₅COOC₂H₅ Clear, colorless liquid.

**Refractive index** <2.45°: n₂₀°: 1.502 – 1.507

**Specific gravity** <2.56°: d₂₀°: 1.045 – 1.053

**Ethyl n-caprylate** C₁₀H₂₀O₂ Clear and colorless to almost colorless liquid.

**Specific gravity** <2.56°: d₂₀°: 0.864 – 0.871

**Purity** Related substances—Dissolve 0.1 g of ethyl n-caprylate in 10 mL of dioxane and use this solution as the sample solution. Pipet 1 mL of the sample solution, add dichloromethane to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 5 μL of each of the sample solution and standard solution (1) as directed under Gas Chromatography <2.02> according to the following conditions, and measure each peak area from these solutions by the automatic integration method: the total peak areas other than ethyl n-caprylate from the sample solution is not larger than the peak area of ethyl n-caprylate from the standard solution (1).

**Operating conditions**

Proceed the operating conditions in the Assay under Men-
Ethyl parahydroxybenzoate \( \text{HOC}_2\text{H}_3\text{COOC}_2\text{H}_3 \) [Same as the namesake monograph]

2-Ethyl-2-phenylmalondiamide \( \text{C}_1\text{H}_3\text{O}_2\text{N}_2 \) White, odorless crystals. Soluble in ethanol (95), and very slightly soluble in water. Melting point: about 120°C (with decomposition).

Purity Related substances—To 5.0 mg of 2-ethyl-2-phenylmalondiamide add 4 mL of pyridine and 1 mL of bis-trimethylsilylaceton, shake thoroughly, and heat at 100°C for 5 minutes. After cooling, add pyridine to make exactly 10 mL, and use this solution as the sample solution. Perform the test with 2 \( \mu \)L of the sample solution as directed under Gas Chromatography (2.02) according to the conditions in the Purity (3) under Primidone: any peak other than the peaks of 2-ethyl-2-phenylmalondiamide and the solvent does not appear. Adjust the detection sensitivity so that the peak height of 2-ethyl-2-phenylmalondiamide obtained from 2 \( \mu \)L of the sample solution is about 80% of the full scale, and the time range of measurement is about twice as long as the retention time of 2-ethyl-2-phenylmalondiamide beginning after the solvent peak.

Ethyl propionate \( \text{CH}_3\text{CH}_2\text{COOC}_2\text{H}_5 \) Colorless, clear liquid.

Specific gravity \( d^25_0 \): 0.890 – 0.892

Etidronate disodium for assay \( \text{C}_10\text{H}_15\text{NO}_2\cdot\text{P}_2 \) [Same as the monograph Ethidronate Disodium. When dried, it contains not less than 99.0% of \( \text{C}_10\text{H}_15\text{NO}_2\cdot\text{P}_2 \).]

Etilerfrine hydrochloride \( \text{C}_{10}\text{H}_{15}\text{NO}_2\cdot\text{HCl} \) [Same as the namesake monograph]

Etilerfrine hydrochloride for assay \( \text{C}_{10}\text{H}_{15}\text{NO}_2\cdot\text{HCl} \) [Same as the monograph Etilerfrine Hydrochloride. When dried, it contains not less than 99.0% of etilerfrine hydrochloride (\( \text{C}_{10}\text{H}_{15}\text{NO}_2\cdot\text{HCl} \)).]

Etizolam for assay \( \text{C}_{17}\text{H}_{15}\text{ClN}_4\text{S} \) [Same as the monograph Etizolam. When dried, it contains not less than 99.0% of etizolam (\( \text{C}_{17}\text{H}_{15}\text{ClN}_4\text{S} \)).]

Factor Xa It is prepared from lyophilization of Factor Xa which has been prepared from bovine plasma. White or pale yellow masses or powder.

Purity Clarity and color of solution—Dissolve 71 \( \text{nkat,} \text{2222} \) of it in 10 mL water; the solution is clear and colorless or pale yellow.

Content: not less than 75% and not more than 125% of the label.

Factor Xa TS Dissolve 71 \( \text{nkat,} \text{2222} \) of factor Xa in 10 mL of water.

Famotidine for assay \( \text{C}_8\text{H}_{15}\text{N}_7\text{O}_2\text{S}_3 \) [Same as the monograph Famotidine. When dried, it contains not less than 99.0% of famotidine (\( \text{C}_8\text{H}_{15}\text{N}_7\text{O}_2\text{S}_3 \)), and when proceed as directed in the Purity (3), the total related substance is not more than 0.4%.]

Fatty oil Same as the fatty oil under the monograph.

Fehling’s TS The copper solution—Dissolve 34.66 g of copper (II) sulfate pentahydrate in water to make 500 mL. Keep this solution in a glass-stoppered bottles in well-filled. The alkaline tartrate solution—Dissolve 173 g of potassium sodium tartrate tetrahydrate and 50 g of sodium hy-
droxide in water to make 500 mL. Preserve this solution in a polyethylene container.

Before use, mix equal volumes of both solutions.

**Fehling’s TS for amylolytic activity test** The copper solution—Dissolve 34.660 g of copper (II) sulfate pentahydrate, accurately weighed, in water to make exactly 500 mL. Preserve this solution in well-filled, glass-stoppered bottles.

The alkaline tartrate solution—Dissolve 173 g of potassium sodium tartrate tetrahydrate and 50 g of sodium hydroxide in water to make exactly 500 mL. Preserve this solution in polyethylene containers.

Before use, mix exactly equal volumes of both solutions.

**Ferric ammonium citrate** See ammonium iron (III) citrate.

**Ferric ammonium sulfate** See ammonium iron (III) sulfate dodecahydrate.

**Ferric ammonium sulfate TS** See ammonium iron (III) sulfate TS.

**Ferric ammonium sulfate TS, dilute** See ammonium iron (III) sulfate TS, dilute.

**Ferric chloride** See iron (III) chloride hexahydrate.

**Ferric chloride-acetic acid TS** See iron (III) chloride-acetic acid TS.

**Ferric chloride-iodine TS** See iron (III) chloride-iodine TS.

**Ferric chloride-methanol TS** See iron (III) chloride-methanol TS.

**Ferric chloride-pyridine TS, anhydrous** See iron (III) chloride-pyridine TS, anhydrous.

**Ferric chloride TS** See iron (III) chloride TS.

**Ferric chloride TS, acidic** See iron (III) chloride TS, acidic.

**Ferric chloride TS, dilute** See iron (III) chloride TS, dilute.

**Ferric nitrate** See iron (III) nitrate TS.

**Ferric nitrate TS** See iron (III) nitrate TS.

**Ferric perchlorate** See iron (III) perchlorate hexahydrate.

**Ferric perchlorate-dehydrated ethanol TS** See iron (III) perchlorate-dehydrated ethanol TS.

**Ferric salicylate TS** See iron salicylate TS.

**Ferric sulfate** See iron (III) sulfate n-hydrate.

**Ferric sulfate TS** See iron (III) sulfate TS.

**Ferrous ammonium sulfate** See ammonium iron (II) sulfatehexahydrate.

**Ferrous sulfate** See iron (II) sulfate heptahydrate.

**Ferrous sulfate TS** See iron (II) sulfate TS.

**Ferrous sulfide** See iron (II) sulfide.

**Ferrous tartrate TS** See iron (II) tartrate TS.

**Ferrous thiocyanate TS** See iron (II) thiocyanate TS.

**Ferrous trisodium pentacyanoamine TS** See iron (II) trisodium pentacyanoamine TS.

**(E)-Ferulic acid** C_{16}H_{18}O_{4} White to light yellow, crystals or crystalline powder. Freely soluble in methanol, soluble in ethanol (99.5), and practically insoluble in water.

Melting point: 173 – 176°C.

**Identification**—Determine the absorption spectrum of a solution in methanol (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry. It exhibits maxima between 215 nm and 219 nm, between 231 nm and 235 nm, and between 318 nm and 322 nm.

**Purity** Related substances—Dissolve 1 mg in 1 mL of methanol. Proceed the test with 2 µL of this solution as directed in the Identification (II) under Hochuekkito Extract: no spot other than the principle spot of around Rf 0.6 appears.

**Fetal calf serum** Serum obtained from fetal calves. Interleukin-2 dependent cell growth suppression substance is removed by heat at 56°C for 30 min before use.

**Fibrinogen** Fibrinogen is prepared from human or bovine blood by fractional precipitation with ethanol or ammonium sulfate. It may contain citrate, oxalate and sodium chloride. A white, amorphous solid. Add 1 mL of isotonic sodium chloride solution to 10 mg of fibrinogen. It, when warmed to 37°C, dissolves with a slight turbidity, and clots on the subsequent addition of 1 unit of thrombin.

**1st Fluid for disintegration test** See 1st fluid for dissolution test.

**1st Fluid for dissolution test** Dissolve 2.0 g of sodium chloride in 7.0 mL of hydrochloric acid and water to make 1000 mL. It is clear and colorless, and has a pH of about 1.2.

**Fixed oil** Same as the vegetable oils under the monograph.

**Flecainide acetate** C_{17}H_{20}F_{6}N_{2}O_{3}.C_{2}H_{4}O_{2} [Same as the namesake monograph]

**Flecainide acetate for assay** C_{17}H_{20}F_{6}N_{2}O_{3}.C_{2}H_{4}O_{2} [Same as the monograph Flecainide Acetate. When dried, it contains not less than 99.0% of flecainide acetate (C_{17}H_{20}F_{6}N_{2}O_{3}.C_{2}H_{4}O_{2}). Additionally, when perform the test as directed in the Purity (3), the sample solution does not show the spot corresponding to the spot obtained from the standard solution, and when perform the test as directed in the Purity (4), the total area of the peaks other than flecainide is not larger than the peak area of flecainide from the standard solution.]

9-Fluorenylmethyl chloroformate C_{13}H_{11}ClO_{2} White crystals or crystalline powder. Melting point <2.60º: 60 – 63ºC

**Flopropione** C_{8}H_{16}O_{4} [Same as the namesake monograph]

**Flopropione for assay** C_{8}H_{16}O_{4} [Same as the monograph Flopropione. It contains not less than 99.0% of flopropione (C_{8}H_{16}O_{4}: 182.17), calculated on the dehydrated basis.]

**Fluid thioglycolate medium** See the Sterility Test <4.06>.
Fluocinolone acetonide C_{24}H_{30}F_{2}O_{6} [Same as the namesake monograph]

9-Fluorenymethyl chloroformate C_{12}H_{11}ClO_{2} Prepared for amino acid analysis or biochemistry.

Fluorescein C_{2}H_{5}O_{3} An yellowish red powder.

**Identification**—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry: it exhibits absorption at the wave numbers of about 1597 cm~^{-1}, 1466 cm~^{-1}, 1389 cm~^{-1}, 1317 cm~^{-1}, 1246 cm~^{-1}, 1247 cm~^{-1}, 1213 cm~^{-1}, 1114 cm~^{-1} and 849 cm~^{-1}.

Fluorescein sodium C_{20}H_{10}Na_{2}O_{5} [Same as the namesake monograph].

Fluorescein sodium TS Dissolve 0.2 g of fluorescein sodium in water to make 100 mL.

4-Fluorobenzoic acid C_{6}H_{5}FO_{2} White, crystals or crystalline powder.

**Identification**—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry: it exhibits absorption at the wave numbers of about 1684 cm~^{-1}, 1606 cm~^{-1} and 1231 cm~^{-1}.

**Melting point** 182 – 188°C

1-Fluoro-2,4-dinitrobenzene C_{6}H_{3}(NO_{2})_{2}F Light yellow liquid or crystalline masses. Melting point: about 25°C.

**Identification**—Determine the infrared absorption spectrum as directed in the liquid film method as directed under Infrared Spectrophotometry: it exhibits absorption at the wave numbers of about 3110 cm~^{-1}, 1743 cm~^{-1}, 1546 cm~^{-1}, 1538 cm~^{-1}, 1365 cm~^{-1}, 1334 cm~^{-1}, 1262 cm~^{-1} and 743 cm~^{-1}.

Preserve in a light-resistant tight container.

7-Fluoro-4-nitrobenzo-2-oxa-1,3-diazole C_{19}H_{13}ClF_{3}O_{7} Prepared for amino acid analysis or biochemistry.

Flurazepam for assay C_{21}H_{18}ClF_{5}N_{3}O Prepared as the monograph Flurazepam. When dried, it contains not less than 99.0% of flurazepam (C_{21}H_{18}ClF_{5}N_{3}O).

Flutoprazepam for assay C_{19}H_{16}ClF_{5}N_{2}O Prepared as the monograph Flutoprazepam. When dried, it contains not less than 99.5% of flutoprazepam (C_{19}H_{16}ClF_{5}N_{2}O).

Folic acid C_{19}H_{19}N_{7}O_{6} [Same as the namesake monograph]

Folin’s TS Place 20 g of sodium tungstate (VI) dihydrate, 5 g of sodium molybdate (VI) dihydrate and about 140 mL of water in a 300-mL volumetric flask, add 10 mL of diluted phosphoric acid (17 in 20) and 20 mL of hydrochloric acid, and boil gently using a reflux condenser with ground-glass joints for 10 hours. To the mixture add 30 g of lithium sulfate monohydrate and 10 mL of water, and then add a very small quantity of bromine to change the deep green color of the solution to yellow. Remove the excess bromine by boiling for 15 minutes without a condenser, and cool. Add water to make 200 mL, and filter through a glass filter. Store it free from dust. Use this solution as the stock solution, and dilute with water to the directed concentration before use.

Folin’s TS, dilute Titrate 2.50 Folin’s TS with 0.1 mol/L sodium hydroxide VS (indicator: phenolphthalein TS), and determine the acid concentration. Prepare by adding water to Folin’s TS so the acid concentration is 1 mol/L.

**Formaldehyde solution** HCHO [K 8872, Special class]

**Formaldehyde solution-sulfuric acid TS** Add 1 drop of formaldehyde solution to 1 mL of sulfuric acid. Prepare before use.

**Formaldehyde solution TS** To 0.5 mL of formaldehyde solution add water to make 100 mL.

**Formaldehyde TS, dilute** See Test Methods for Plastic Containers <7.02>.

**Formalin** See formaldehyde solution.

**Formalin TS** See formaldehyde solution TS.

**Formalin-sulfuric acid TS** See formaldehyde solution-sulfuric acid TS.

**Formamide** HCONH_{2} [K 8873, Special class]

**Formamide for Karl Fischer method** HCONH_{2} [K 8873, Special class; water content per g of formamide for Karl Fischer method should be not more than 1 mg.]

**Formic acid** HCOOH [K 8824, Special class, specific gravity: not less than 1.21].

2-Formylbenzoic acid CHOC_{6}H_{4}COOH White crystals. Melting point: 97 – 99°C

**Content**: not less than 99.0%. Assay—Weigh accurately about 0.3 g of 2-formylbenzoic acid, previously dried (in vacuum, phosphorus (V) oxide, 3 hours), dissolve in 50 mL of freshly boiled and cooled water, and titrate 2.50 with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of phenol red TS).

Each mL of 0.1 mol/L sodium hydroxide VS = 15.01 mg of C_{6}H_{4}O_{2}

**Freund’s complete adjuvant** A suspension of 5 mg of mycobacteria of Corynebacterium butyricum, killed by heating, in 10 mL of a mixture of mineral oil and aracel A (17:3).

**Fruuctose** C_{6}H_{12}O_{6} [Same as the namesake monograph]

**Fuchsin** A lustrous, green, crystalline powder or mass, slightly soluble in water and in ethanol (95). **Loss on drying** 2.41: 17.5 – 20.0% (1 g, 105°C, 4 hours). **Residue on ignition** 2.44: not more than 0.1% (1 g).

**Fuchsin-ethanol TS** Dissolve 11 g of fuchsin in 100 mL of ethanol (95).

**Fuchsin-sulfuric acid TS** Dissolve 0.2 g of fuchsin in 120 mL of hot water, and allow the solution to cool. Add a solution prepared by dissolving 2 g of anhydrous sodium sulfate in 20 mL of water, then add 2 mL of hydrochloric acid and water to make 200 mL, and allow to stand for at least 1 hour. Prepare before use.

**Fumaric acid for thin-layer chromatography** C_{4}H_{4}O_{4} White, crystalline powder, odorless, and has a characteristic acid taste.

**Purity**—Perform the test as directed in the Identification (5) under Clemastine Fumarate: any spot other than the principal spot at the RT value of about 0.8 does not appear.
Fuming nitric acid  See nitric acid, fuming.

Fuming sulfuric acid  See sulfuric acid, fuming.

Furfural  C₅H₄O₂  A clear, colorless liquid.

Specific gravity  1.256  d₅₁₀:  1.600 – 1.165

Distillation range  257°  160 – 163°C, not less than 95 vol%.

D-Galactosamine hydrochloride  C₁₇H₂₄O₁₀·HCl  White powder. Melting point: about 180°C (with decomposition).

Optical rotation  <2.49° [α]D: +90 – +97° (1 g, water, 100 mL, 100 mm).

Galactose  See D-galactose.

D-Galactose  C₆H₁₂O₆  White crystals, granules or powder.

Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry 2.25: it exhibits absorption at the wave numbers of about 3390 cm⁻¹, 3210 cm⁻¹, 3140 cm⁻¹, 1151 cm⁻¹, 1068 cm⁻¹, 956 cm⁻¹, 836 cm⁻¹, 765 cm⁻¹ and 660 cm⁻¹.

Optical rotation  <2.49° [α]D: +79 – +82° (desiccator (silica gel), 2.5 g after drying for 18 hours, diluted ammonia solution (28) (1 in 300), 25 mL, 100 mm).

Gallic acid  See gallic acid monohydrate.

Gallic acid monohydrate  C₆H₄(OH)₂COOH·H₂O  White to pale yellowish white, crystals or powder.

Melting point  <2.60°: about 260°C (with decomposition).

Gelatin  [Same as the namesake monograph]

Gelatin, acid-treated  [Same as the monograph Gelatin. Its isoelectric point is at pH between 7.0 and 9.0]

Gelatin peptone  See peptone, gelatin.

Gelatin-phosphate buffer solution  pH 7.0  Dissolve 1.15 g of sodium dihydrogen phosphate dihydrate and 5.96 g of disodium hydrogen phosphate dodecahydrate and 5.4 g of sodium chloride in 500 mL of water. Dissolve 1.2 g of gelatin to this solution by heating, and after cooling add water to make 600 mL.

Gelatin-phosphate buffer solution, pH 7.4  To 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution add 39.50 mL of 0.2 mol/L sodium hydroxide VS and 50 mL of water. Dissolve 0.2 g of gelatin to this solution by heating, then after cooling adjust to pH 7.4 with 0.2 mol/L sodium hydroxide TS, and add water to make 200 mL.

Gelatin-phosphate buffer solution, pH 8.0  Dissolve 40 g of 2-amino-2-hydroxyethyl-1,3-propanediol and 5.4 g of sodium chloride in 500 mL of water. Add 1.2 g of gelatin to dissolve by heating, adjust to pH 8.0 with dilute hydrochloric acid after cooling, and add water to make 600 mL.

Gelatin TS  Dissolve 1 g of gelatin in 50 mL of water by gentle heating, and filter if necessary. Prepare before use.

Geniposide for assay  Use geniposide for thin-layer chromatography meeting the following additional specifications.

Absorbance  <2.24° E₁cm (240 nm): 249 – 269 [10 mg dried in a desiccator (reduced pressure of not exceeding 0.67 kPa, phosphorus (V) oxide) for 24 hours, diluted methanol (1 in 2), 500 mL].

Purity  Related substances—Dissolve 5 mg of geniposide for assay in 50 mL of diluted methanol (1 in 2), and use this solution as the sample solution. Pipet 1 mL of the sample solution, add diluted methanol (1 in 2) to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 10 µL each of the sample solution and standard solution (1) as directed under Liquid Chromatography 2.01 according to the following conditions, and measure each peak area of the both solutions by the automatic integration method: the total area of the peaks other than geniposide from the sample solution is not larger than the peak area of geniposide from the standard solution (1). Operating conditions

Proceed as directed in the Assay under Gardenia Fruit except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add diluted methanol (1 in 2) to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of geniposide obtained from 10 µL of the standard solution (2) can be measured by the automatic integration method and the peak height of geniposide obtained from 10 µL of the standard solution (1) shows about 20% of the full scale.

Time span of measurement: About 3 times as long as the retention time of geniposide beginning after the solvent peak.

Geniposide for component determination  See geniposide for assay.

Geniposide for thin-layer chromatography  C₁₇H₂₅O₁₀  White crystals or crystalline powder. Melting point: 159 – 163°C.

Purity  Related substances—Dissolve 1.0 mg of geniposide for thin-layer chromatography in exactly 1 mL of methanol, and perform the test with 20 µL of this solution as directed in the Identification (2) under Gardenia Fruit: any spot other than the principal spot at the Rf value of about 0.3 does not appear.

Gentamicin B  C₁₉H₃₂N₄O₁₀  White to pale yellowish white powder. Very soluble in water, and practically insoluble in ethanol (95).

Content:  not less than 80.0%.  Assay—Dissolve a suitable amount of gentamicin B in 0.05 mol/L sulfuric acid TS to make the solution containing 0.1 mg of gentamicin B per mL, and use this solution as the sample solution. Perform the test with 5 µL of the sample solution as directed under Liquid Chromatography 2.01 according to the following conditions.
conditions, and measure each peak area by the automatic integration method. Calculate the amount of gentamicin B by the area percentage method.

Operating conditions

Apparatus, detector, column, column temperature, reaction coil, mobile phase, reagent, reaction temperature, flow rate of the mobile phase, and flow rate of the reagent: Proceed the operating conditions in the Assay under Isepamicin Sulfate.

Time span of measurement: About 3 times as long as the retention time of gentamicin B.

System suitability

Procede the system suitability in the Assay under Isepamicin Sulfate.

**Gentiopicroside for thin-layer chromatography**

C_{48}H_{82}O_{18} A white powder. Freely soluble in water and in methanol, and practically insoluble in diethyl ether. Melting point: about 110°C (with decomposition).

**Purity** Related substances—Dissolve 10 mg of gentiopicroside for thin-layer chromatography in 1 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and methanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed in the Identification (2) under Gentian: the spots other than the principal spot at the Rf value of about 0.4 from the sample solution are not more intense than the spot from the standard solution.

**Giemsa’s TS**

Dissolve 3 g of azure II-eosin Y and 0.8 g of azure II in 250 g of glycerin by warming to 60°C. After cooling, add 250 g of methanol, and mix well. Allow to stand for 24 hours, and filter. Store in tightly stoppered bottles.

Azure II-eosin Y is prepared by coupling eosin Y to azure II. Azure II is the mixture of equal quantities of methylene azure (azure I), prepared by oxidizing methylene blue, and methylene blue.

**Giemsa’s TS, dilute** See Test Methods for Plastic Containers <7.02>.

**[6]-Gingerol for assay**

[6]-Gingerol for thin-layer chromatography. However, it meets the following requirements:

\[ \text{Absorbance } \lt 2.24 \times e_{\text{281 nm}}^{1 \text{cm}} (281 \text{ nm}) : 101 - 112 \text{ mg} (7 \text{ mg, ethanol (99.5), 200 mL}) \]

**Purity** Related substances—Dissolve 5 mg of [6]-gingerol for assay in 5 mL of methanol, and use this as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 50 mL, and use this as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than [6]-gingerol from the sample solution is not larger than the peak area of [6]-gingerol from the standard solution.

Operating conditions

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay (3) under Hangekobokuto Extract.

Time span of measurement: About 6 times as long as the retention time of [6]-gingerol.

System suitability

Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of [6]-gingerol obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.

System performance and system repeatability: Proceed as directed in the system suitability in the Assay (3) under Hangekobokuto Extract.

**[6]-Gingerol for component determination** See [6]-gingerol for assay.

**[6]-Gingerol for thin-layer chromatography**

C_{16}H_{16}O_{4} A yellow-white to yellow, liquid or solid. Freely soluble in methanol, in ethanol (99.5) and in diethyl ether, and practically insoluble in water.

**Identification**—Determine the absorption spectrum of a solution of [6]-gingerol for thin-layer chromatography in ethanol (99.5) (7 in 200,000) as directed under Ultraviolet-visible Spectrophotometry <2.24> it exhibits a maximum between 279 nm and 283 nm.

**Purity** Related substances—Dissolve 1.0 mg of [6]-gingerol for thin-layer chromatography in exactly 2 mL of methanol. Perform the test with 10 μL of this solution as directed in the Identification under Ginger: any spot other than the principal spot at the Rf value of about 0.3 does not appear.

**Ginsenoside Re**

C_{48}H_{70}O_{27}.xH_{2}O A white crystalline powder. It is odorless.

**Purity**—Dissolve 1 mg in diluted methanol (3 in 5) to make 10 mL. Perform the test with 10 μL of this solution as directed under Liquid Chromatography <2.01> according to the conditions directed in the Assay under Ginseng: the total area of the peak other than ginsenoside Re and solvent peak is not more than 1/10 times the total peak area excluding the peak area of the solvent.

**Ginsenoside Re**

C_{68}H_{82}O_{27}.xH_{2}O A white crystalline powder. It is odorless.

**Purity**—Dissolve 1 mg in diluted methanol (3 in 5) to make 10 mL. Perform the test with 10 μL of this solution as directed under Liquid Chromatography <2.01> according to the conditions directed in the Assay under Ginseng: the total area of the peak other than ginsenoside Re and solvent peak is not more than 1/10 times the total peak area excluding the peak area of the solvent.

**Ginsenoside Rg2 for thin-layer chromatography**

C_{42}H_{73}O_{14} White, crystalline powder, having a slight, bitter taste. Freely soluble in methanol and in ethanol (95), and practically insoluble in diethyl ether and in chloroform.

**Melting point** <2.60>: 194 – 196.5°C

**Purity** Related substances—Dissolve 1 mg of ginsenoside Rg2 for thin layer chromatography in 1 mL of methanol, and perform the test with 20 μL of this solution as directed in the Identification (2) under Ginseng: any spot other than the principal spot at the Rf value of about 0.4 does not appear.

**Glacial acetic acid** See acetic acid (100).

**Glacial acetic acid for nonaqueous titration** See acetic acid for nonaqueous titration.

**Glacial acetic acid-sulfuric acid TS** See acetic acid (100)-sulfuric acid TS.
γ-Globulin  A plasma protein obtained from human serum as Cohn’s II and III fractions. White crystalline powder. It contains not less than 98% of γ-globulin in the total protein.

δ-Glucosamine hydrochloride C6H11NO4.HCl White crystals or crystalline powder. 

Content: not less than 98%. Assay—Dissolve about 0.4 g of δ-glucosamine hydrochloride, accurately weighed, in 50 mL of water, add 5 mL of diluted nitric acid (1 in 3), and titrate with 0.1 mol/L silver nitrate VS (potentiometric titration).

Each mL of 0.1 mol/L silver nitrate VS = 21.56 mg of C6H11NO4.HCl

Glucose C6H12O6 [Same as the namesake monograph]

Glucose detection TS Dissolve 1600 units of glucose oxidase, 16 mg of 4-aminopyridine, 145 units of peroxidase and 0.27 g of p-hydroxybenzoic acid in acetic acid (100) in 1 mL of the sample solution, add dilute ethanol to make exactly 200 mL.

Glucose detection TS for penicillin origin β-galactosidase Dissolve glucose oxidase (not less than 500 units), peroxidase (not less than 50 units), 0.01 g of 4-aminopyridine, and 0.1 g of phenol in phosphate buffer, pH 7.2 to make 100 mL.

Glucose oxidase Obtained from Aspergillus niger. White powder. It is freely soluble in water. It contains about 200 Units per mg. One unit indicates an amount of the enzyme which produces 1 μmol of δ-glucono-δ-lactone in 1 minute at 25°C and pH 7.0 from glucose used as the substrate.

Glucose-peptone medium for sterility test See soybean-casein digest medium

Glucose TS Dissolve 30 g of glucose in water to make 100 mL. Prepare as directed under Injections.

4-O-Glucosyl-5-O-methylvisamminol for thin-layer chromatography C23H30N6O7 White crystals or crystalline powder. It is freely soluble in acetic acid (100), sparingly soluble in dimethylsulfoxide, and practically insoluble in water.

Absorbance 2.24  E1%1cm (325 nm): 310 – 350 [2 mg, diluted acetic acid (100) (1 in 500), 200 mL].

Optical rotation 2.49 [α]D = 50 – 60° [0.1 g, diluted acetic acid (100) (1 in 2), 10 mL, 100 mm].

Purity Related substances—Prepare the sample solution by dissolving 5 mg of 7-(glutarylglycyl-L-arginylalanyl)-4-methylcoumarin in 0.5 mL of acetic acid (100), and perform the test as directed under Thin-layer Chromatography 2.03. Spot 5 μL of the sample solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water, pyridine and acetic acid (100) (15:12:10:3) to a distance of about 10 cm, air-dry the plate, and dry more at 80°C for 30 minutes. After cooling, allow the plate to stand for 30 minutes in a box filled with iodine vapors: any observable spot other than the principal spot at the Rf value of about 0.6 does not appear.

7-(Glutarylglycyl-L-arginylalanyl)-4-methylcoumarin TS Dissolve 5 mg of 7-(glutarylglycyl-L-arginylalanyl)-4-methylcoumarin in 0.5 to 1 mL of acetic acid (100), lyophilize, dissolve this in 1 mL of dimethylsulfoxide, and use this solution as the standard solution as solution A. Dissolve 30.0 g of 2-amino-2-hydroxymethyl-1,3-propanediol and 14.6 g of sodium chloride in 400 mL of water, adjust the pH to 8.5 with dilute hydrochloric acid, add water to make 500 mL, and use this solution as solution B. Mix 1 mL of the solution A and 500 mL of the solution B before use.

Glutathione C10H17N3O6S [Same as the namesake monograph]

Glycerin C3H8O3 [Same as the monograph Concentrated Glycerin]

85% Glycerin C3H8O3 [Same as the monograph Glycerin]

Glycine C2H4NO2 [K 8291, Special class]

Glycolic acid C2H3O2

Glycerrhizinic acid for thin-layer chromatography C42H62O16 Colorless or white, sweet, crystalline powder. Freely soluble in hot water and in ethanol (95%), and practically insoluble in diethyl ether. Melting point: 213 – 218°C (with decomposition).

Purity Related substances—Dissolve 10 mg of glycerrhizinic acid for thin-layer chromatography in 5 mL of dilute ethanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add dilute ethanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed in the Identification under Glycerrhiza: the spots other than the principal spot at the Rf value of about 0.3 from the sample solution are not more intense than the spot from the standard solution.

Goat anti-ECP antibody Combine 1 volume of ECP standard substance (equivalent to about 1 mg of protein) and 1 volume of Freund’s complete adjuvant, and immunize goats subcutaneously in the back region with this solution 5 times at 2 week intervals. Harvest blood on the 10th day after completing the immunization to obtain goat antiserum. Goat anti-ECP antibody is obtained by preparing an immobilized ECP column in which ECP standard substance is bound to
spharose 4B and then purifying by affinity column chromatography.

**Description:** Clear and colorless solution.

**Identification:** When sodium lauryl sulfate-supplemented polyacrylamide gel electrophoresis is conducted under non-reducing conditions, the molecular weight of the major band is within the range of $1.30 \times 10^5$ to $1.70 \times 10^5$.

**Protein content:** When determining the protein content using Assay (1) under Celmoleukin (Genetical Recombination), the protein content per mL is 0.2 to 1.0 mg.

**Goat anti-ECP antibody TS** Dilute goat anti-ECP antibody with 0.1 mol/L carbonate buffer solution, pH 9.6 to prepare a solution containing 50 μg protein per mL.

**Griess-Romijn's nitric acid reagent** Triturate thoroughly 1 g of 1-naphthylamine, 10 g of sulfanilic acid and 1.5 g of zinc dust in a mortar.

**Storage**—Preserve in tight, light-resistant containers.

**Griess-Romijn's nitrous acid reagent** Triturate thoroughly 1 g of 1-naphthylamine, 10 g of sulfanilic acid and 89 g of tartaric acid in a mortar.

**Storage**—Preserve in tight, light-resistant containers.

**Guaiacol** CH$_3$OC$_6$H$_4$OH Clear, colorless to yellow liquid or colorless crystals, having a characteristic aroma. Sparingly soluble in water, and miscible with ethanol (95), with diethyl ether and with chloroform. Melting point: about 28°C.

**Purity**—Perform the test with 0.5 μL of guaiacol as directed under Gas Chromatography <2.02> according to the following conditions. Measure each peak area by the automatic integration method, and calculate the amount of guaiacol by the area percentage method: It showed the purity of not less than 99.0%.

**Operating conditions**
- **Detector:** Hydrogen flame-ionization detector
- **Column:** A glass column about 3 mm in inside diameter and 2 m in length, packed with siliceous earth for gas chromatography, 150- to 180-μm in particle diameter, coated with polyethylene glycol 20 M at the ratio of 20%.
- **Column temperature:** A constant temperature of about 200°C.
- **Carrier gas:** Nitrogen.
- **Flow rate:** Adjust the flow rate so that the retention time of guaiacol begins after the solvent peak.
- **Detection sensitivity:** Adjust the detection sensitivity so that the peak height of guaiacol obtained from 0.5 μL of guaiacol is 4 to 6 minutes.
- **Detection sensitivity:** Adjust the detection sensitivity so that the peak height of guaiacol obtained from 0.5 μL of guaiacol is 90% of the full scale.
- **Time span of measurement:** About 3 times as long as the retention time of guaiacol beginning after the solvent peak.

**Guaiacol for assay** C$_7$H$_8$O$_2$ Colorless to yellow clear liquid or colorless crystals with a characteristic, aromatic odor. Miscible with methanol and with ethanol (99.5), and sparingly soluble in water. Congealing point: 25 – 30°C.

**Identification**—Determine the infrared absorption spectrum of guaiacol for assay as directed in the ATR method <2.25>: it exhibits absorption at the wave numbers of about 1595 cm$^{-1}$, 1497 cm$^{-1}$, 1443 cm$^{-1}$, 1358 cm$^{-1}$, 1255 cm$^{-1}$, 1205 cm$^{-1}$, 1108 cm$^{-1}$, 1037 cm$^{-1}$, 1020 cm$^{-1}$, 916 cm$^{-1}$, 833 cm$^{-1}$, and 738 cm$^{-1}$.

**Purity**—Related substances—Perform the test with 0.5 μL of guaiacol for assay as directed under Gas Chromatography <2.02> according to the following conditions. Determine each peak area by the automatic integration method: the total area of the peaks other than the peak of guaiacol is not more than 2.0%.

**Operating conditions**
- **Detector:** A hydrogen flame-ionization detector.
- **Column:** A fused silica column 0.25 mm in inside diameter and 60 m in length, coated inside with polyethyleneoxide for gas chromatography in 0.25 to 0.5 μm in thickness.
- **Column temperature:** Raise the temperature from 100°C to 130°C at a rate of 5°C per minute, raise to 140°C at a rate of 2°C per minute, raise to 200°C at a rate of 15°C per minute, and maintain at 200°C for 2 minutes.
- **Injection port temperature:** 200°C.
- **Detector temperature:** 250°C.
- **Carrier gas:** Helium.
- **Flow rate:** Adjust the flow rate so that the retention time of guaiacol is about 8 minutes.
- **Split ratio:** 1:50.

**System suitability**
- **Test for required detectability:** Weigh accurately about 70 mg of guaiacol for assay, add methanol to make exactly 100 mL, and use this solution for the solution for system suitability test. Confirm that the peak area of guaiacol obtained from 1 μL of the solution for system suitability test is equivalent to 0.08 to 0.16% of that of guaiacol obtained when 0.5 μL of guaiacol for assay is injected.

**System performance:** When the procedure is run with 1 μL of the solution for system suitability test under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of guaiacol are not less than 200,000 and not more than 1.5, respectively.

**System repeatability:** When the test is repeated 6 times with 1 μL of the solution for system suitability test under the above operating conditions, the relative standard deviation of the peak area of guaiacol is not more than 2.0%.

**Guaifenesin** C$_{10}$H$_{14}$O$_4$ [Same as the namesake monograph]

**Guanine** C$_5$H$_5$N$_5$O White to pale yellowish white powder.

**Absorbance** <2.24> Weigh accurately about 10 mg of guanine, dissolve in 20 mL of dilute sodium hydroxide TS, and add 2 mL of 1 mol/L hydrochloric acid TS and 0.1 mol/L hydrochloric acid TS to make exactly 1000 mL. Determine the absorbances, $E_{1\%}$, of this solution at 248 nm and 273 nm: they are between 710 and 770, and between 460 and 500, respectively.

**Loss on drying** <2.41>: Not more than 1.5% (0.5 g, 105°C, 4 hours).

**Haloperidol for assay** C$_{19}$H$_{23}$ClFNO$_2$ [Same as the monograph Haloperidol]

**Hanus' TS** Dissolve 20 g of iodine monobromide in 1000 mL of acetic acid (100). Preserve in light-resistant, glass-stopped bottles, in a cold place.

**Heart infusion agar medium** Prepared for biochemical tests.

**Heavy hydrogenated solvent for nuclear magnetic resonance spectroscopy** Prepared for nuclear magnetic resonance spectroscopy. Heavy hydrogenated chloroform (CDCl$_3$), heavy hydrogenated dimethyl sulfoxide [(CD$_3$)$_2$O]}
with silica gel for 24 hours, methanol, 50 mL, 100 mm). Larger than the peak area of hesperidin obtained with the automatic integration method: the total area of the peaks hydroxyethylpiperazine-
<
under Liquid Chromatography each of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry.

After 24 hours, mix these two prepared solutions. Allow to stand for 8 hours in a wide-mouthed bottle without using a stopper, and filter.

Related substances—Dissolve 1 mg in 2 mL of diluted sulfuric acid (3 in 20) to make 40 mL. Prepare a desiccator (silica gel) for 24 hours, methanol, 500 mL.

Purity Related substances—Dissolve 1 mg in 2 mL of methanol. Proceed the test with 20 μL of this solution as directed in the Identification (6) under Hochuekkito Extract: no spot other than the principle spot of around Rf 0.3 appears.

Hexaammonium heptamolybdate-cerium (IV) sulfate TS Dissolve 2.5 g of hexaammonium heptamolybdate tetrhydrate and 1.0 g of cerium (IV) sulfate tetrahydrate in diluted sulfuric acid (3 in 50) to make 100 mL. Prepare before use.

Hexaammonium heptamolybdate-sulfuric acid TS Dissolve 1.0 g of hexaammonium heptamolybdate tetrhydrate in diluted sulfuric acid (3 in 20) to make 40 mL. Prepare before use.

Hexaammonium heptamolybdate tetrhydrate (NH₄)₂Mo₇O₂₄·4H₂O [K 8905, Special class]

Hexaammonium heptamolybdate TS dissolve 21.2 g of hexaammonium heptamolybdate tetrhydrate in water to make 200 mL (10%). Prepare before use.

Hexamethylenetetramine (CH₂)₄N₄ [K 8847, Special class]

Hexamethylenetetramine TS Dissolve 2.5 g of hexamethylenetetramine in 25 mL of water.

Hexane C₆H₁₄ [K 8848, Special class]

Hexane for liquid chromatography CH₃(CH₂)₅CH₃ Colorless, clear liquid. Miscible with ethanol (95), with diethyl ether, with chloroform and with benzene. Boiling point < 2.57>: about 69°C

Purity (1) Ultraviolet absorbive substances—Read the absorbances of hexane for liquid chromatography as directed under Ultraviolet-visible Spectrophotometry <2.24>, using water as the blank: not more than 0.3 at the wave-
length of 210 nm, and not more than 0.01 between 250 nm and 400 nm.

(2) Peroxide—To a mixture of 100 mL of water and 25 mL of dilute sulfuric acid add 25 mL of a solution of potassium iodide (1 in 10) and 20 g of hexane for liquid chromatography. Stopper tightly, shake, and allow to stand in a dark place for 15 minutes. Titrate \( < 2.50 \) this solution, while shaking well, with 0.01 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS). Perform a blank determination in the same manner.

**n-Hexane for liquid chromatography** See hexane for liquid chromatography.

**Hexane for purity of crude drug** [K 8848, Special class] Use hexane meeting the following additional specification. Evaporate 300.0 mL of hexane for purity of crude drug in vacuum at a temperature not higher than 40°C, add the hexane to make exactly 1 mL, and use this solution as the sample solution. Separately, dissolve 2.0 mg of \( \gamma \)-BHC in hexane to make exactly 100 mL. Pipet 1 mL of this solution, and add hexane to make exactly 100 mL. Further pipet 2 mL of this solution, add hexane to make exactly 100 mL, and use this solution as the standard solution I. Perform the test with exactly 1 \( \mu L \) each of the sample solution and standard solution I as directed under Gas Chromatography \( < 2.02 \) according to the following operating conditions, and determine each peak area by the automatic integration method: the total area of peak other than the solvent peak from the sample solution is not larger than the peak area of \( \gamma \)-BHC from the standard solution I.

**Operating conditions** Proceed the operating conditions in the Purity (2) under Crude Drugs Test \( < 5.01 \), except detection sensitivity and time span of measurement.

**Detection sensitivity:** Pipet 1 mL of the standard solution I, add hexane to make exactly 20 mL, and use this solution as the standard solution II. Adjust the detection sensitivity so that the peak area of \( \gamma \)-BHC obtained from 1 \( \mu L \) of the standard solution II can be measured by the automatic integration method, and the peak height of \( \gamma \)-BHC from 1 \( \mu L \) of the standard solution I is about 20% of the full scale.

**Time span of measurement:** About three times as long as the retention time of \( \gamma \)-BHC beginning after the solvent peak.

**Hexane for ultraviolet-visible spectrophotometry** [K 8848, Special class]. When determining the absorbance of hexane for ultraviolet-visible spectrophotometry as directed under Ultraviolet-visible Spectrophotometry \( < 2.24 \), using water as the blank solution, its value is not more than 0.10 at 220 nm and not more than 0.02 at 260 nm, and it has no characteristic absorption between 260 nm and 350 nm.

**n-Hexane for ultraviolet-visible spectrophotometry** See hexane for ultraviolet-visible spectrophotometry.

**Hexyl parahydroxybenzoate** \( C_{13}H_{18}O_3 \) White crystals or crystalline powder.

**Melting point** \( < 2.60 \): 49 – 53°C

**Content:** Not less than 98.0%. Assay—Proceed as directed in the Assay under Ethyl Parahydroxybenzoate.

Each mL of 1 mol/L sodium hydroxide VS = 222.3 mg of \( C_{13}H_{18}O_3 \)

**Hirsutine** See hirsutine for thin-layer chromatography.

**Hirsutine for assay** \( C_{22}H_{28}N_2O_3 \) Hirsutine for thin-layer chromatography. It meets the following requirements. \( \text{Absorbance} \ < 2.24\% \): \( E_1^1cm \) (245 nm): 354 – 389 (5 mg calculated on the anhydrous basis, a mixture of methanol and dilute acetic acid (7:3), 500 mL).

**Purity** Related substances—Dissolve 5 mg of hirsutine for assay in 100 mL of a mixture of methanol and dilute acetic acid (7:3), use this solution as the sample solution. Pipet 1 mL of this solution, add a mixture of methanol and dilute acetic acid (7:3) to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 20 \( \mu L \) each of the sample solution and standard solution as directed under Liquid-chromatography \( < 2.02 \) according to the following conditions. Determine the peak area of each solution by the automatic integration method: the total area of the peaks other than hirsutine obtained from the sample solution is not larger than the peak area of hirsutine from the standard solution.

**Operating conditions**

**Detector, column, column temperature, mobile phase, and flow rate:** Proceed as directed in the operating conditions in the Assay under Uncaria Hook.

**Time span of measurement:** About 1.5 times as long as the retention time of hirsutine, beginning after the solvent peak.

**System suitability** Test for required detectability: Pipet 1 mL of the standard solution, add a mixture of methanol and dilute acetic acid (7:3) to make exactly 20 mL. Confirm that the peak area of hirsutine obtained with 20 \( \mu L \) of this solution is equivalent to 3.5 to 6.5% of that with 20 \( \mu L \) of the standard solution.

**System performance:** Proceed as directed in the system suitability in the Assay under Uncaria Hook.

**System repeatability:** When the test is repeated 6 times with 20 \( \mu L \) of the standard solution under the above operating conditions, the relative standard deviation of the peak area of hirsutine is not more than 1.5%.

**Hirsutine for thin-layer chromatography** \( C_{22}H_{28}N_2O_3 \) A white or light orange crystalline powder or powder. Very soluble in methanol, freely soluble in ethanol (99.5), and practically insoluble in water. Melting point: about 105°C.

**Identification**—Determine the absorption spectrum of a solution of hirsutine for thin-layer chromatography in a mixture of methanol and dilute acetic acid (7:3) (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry \( < 2.24 \): it exhibits a maximum between 287 nm and 291 nm.

**Purity** Related substances—Dissolve 1.0 mg of hirsutine for thin-layer chromatography in 1 mL of methanol, and use this solution as the sample solution. Perform the test with this solution as directed under Thin-layer Chromatography \( < 2.60 \). Spot 10 \( \mu L \) of the sample solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water and acetic acid (100) (7:2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm); no spot other than the principal spot at around \( R_f \) 0.55 appears.

**L-Histidine** \( C_6H_9N_3O_2 \) [Same as the namesake monograph]

**L-Histidine hydrochloride** See L-histidine hydrochloride monohydrate.
1-Histidine hydrochloride monohydrate
\[ C_6H_7NO_2 \cdot HCl \cdot H_2O \quad [K \, 9050, \text{Special class}] \]

Homatropine hydrobromide \[ C_{16}H_{23}NO_3 \cdot HBr \quad [\text{Same as the namesake monograph}] \]

Honokiol \[ C_{19}H_{18}O_2 \cdot xH_2O \quad \text{Odorless white, crystals or crystalline powder.} \]

Purity—Dissolve 1 mg of honokiol in the mobile phase to make 10 mL, and use this solution as the sample solution. Perform the Liquid Chromatography \( <2.0D \) with 10 mL of the sample solution as directed in the Assay under Magnolia Bark: when measure the peak areas 2 times as long as the retention time of magnolone, the total area of peaks other than honokiol is not larger than 1/10 times the total area of the peaks other than the solvent peak.

Horseradish peroxidase An oxidase (Molecular weight: about 40,000) derived from horseradish.

Horse serum Collect the blood from horse in a flask, coagulate, and allow to stand at room temperature until the serum is separated. Transfer the separated serum in glass containers, and preserve at \(-20^\circ\text{C}\).

Human antithrombin III Serine protease inhibition factor obtained from normal plasma of human. It is a protein, which inhibits the activities of thrombin and activated blood coagulation factor X. It contains not less than 300 Units per mg protein. One unit indicates an amount of the antithrombin III which inhibits 1 unit of thrombin at 25°C under the existence of heparin.

Human chorionic gonadotrophin TS Weigh accurately a suitable amount of Human Chorionic Gonadotrophin according to the labeled amount, and dissolve in bovine serum albumin-sodium chloride-phosphate buffer solution, pH 7.2 so that each mL contains 80 human chorionic gonadotrophin Units.

Human insulin desamide substance-containing TS Dissolve 1.5 mg of Insulin Human in 1 mL of 0.01 mol/L hydrochloric acid TS, allow to stand at 25°C for 3 days, and when the procedure is run with this solution according to the conditions as directed in the Purity (1) under Insulin Human (Genetical Recombination), the solution contains about 5% of the desamide substance.

Human insulin dimer-containing TS Allow to stand Insulin Human (Genetical Recombination) at 25°C for 10 days or more, and dissolve 4 mg of this in 1 mL of 0.01 mol/L hydrochloric acid TS.

Human normal plasma Dissolve an amount of dried human normal plasma powder, equivalent to 1 mL of the normal plasma of human, in 1 mL of water. Store between 2 and 10°C, and use within one week.

Human serum albumin for assay White to pale-yellow powder. Albumin content is at least 99%. Convert to the dehydrate using the following water determination method.

Water content \( <2.4D \) \( (0.2 \text{ g, volumetric titration, direct titration}) \). However, in a dehydration solvent, use a mixture of pyridine for water determination and ethylene glycol for water determination \( (5:1) \).

Hydralazine hydrochloride \[ C_6H_7N_2 \cdot HCl \quad [\text{Same as the namesake monograph}] \]

Hydrazine hydrochloride for assay \[ C_6H_7N_2 \cdot HCl \quad [\text{Same as the monograph Hydralazine Hydrochloride. When dried, it contains not less than 99.0% of hydralazine hydrochloride (C_6H_7N_2 \cdot HCl).}] \]

Hydrazine monohydrate \[ NH_2NH_2 \cdot H_2O \quad \text{Colorless liquid, having a characteristic odor.} \]

Hydrazine sulfate See hydrazinium sulfate.

Hydrazinium sulfate \[ NH_2H_4SO_4 \quad [K \, 8992, \text{Special class}] \]

Hydrazinium sulfate TS Dissolve 1.0 g of hydrazinium sulfate in water to make 100 mL.

Hydrobromic acid \[ HBr \quad [K \, 8509, \text{Special class}] \]

Hydrochloric acid \[ HCl \quad [K \, 8180, \text{Special class}] \]

Hydrochloric acid-ammonium acetate buffer solution, pH 3.5 Dissolve 25 g of ammonium acetate in 45 mL of 6 mol/L hydrochloric acid TS, and add water to make 100 mL.

Hydrochloric acid, dilute Dilute 23.6 mL of hydrochloric acid with water to make 100 mL (10%).

Hydrochloric acid-ethanol TS See hydrochloric acid-ethanol (95) TS.

Hydrochloric acid-ethanol (95) TS Dilute 23.6 mL of hydrochloric acid with ethanol to make 100 mL.

0.01 mol/L Hydrochloric acid-methanol TS To 20 mL of 0.5 mol/L hydrochloric acid TS add methanol to make 1000 mL.

0.05 mol/L Hydrochloric acid-methanol TS To 100 mL of 0.5 mol/L hydrochloric acid TS add methanol to make 1000 mL.

Hydrochloric acid-2-propanol TS Add 0.33 mL of hydrochloric acid to 100 mL of 2-propanol, mix, and store in a dark and cool place.

Hydrochloric acid-potassium chloride buffer solution, pH 2.0 To 10.0 mL of 0.2 mol/L hydrochloric acid VS add 88.0 mL of 0.2 mol/L potassium chloride TS, adjust the pH to 2.0 ± 0.1 with 0.2 mol/L hydrochloric acid VS or 0.2 mol/L potassium chloride TS, then add water to make 200 mL.

Hydrochloric acid, purified Add 0.3 g of potassium permanganate to 1000 mL of diluted hydrochloric acid (1 in 2), distill, discard the first 250 mL of the distillate, and collect the following 500 mL of the distillate.

0.001 mol/L Hydrochloric acid TS Dilute 10 mL of 0.1 mol/L hydrochloric acid TS with water to make 1000 mL.

0.01 mol/L Hydrochloric acid TS Dilute 100 mL of 0.1 mol/L hydrochloric acid TS with water to make 1000 mL.

0.02 mol/L Hydrochloric acid TS Dilute 100 mL of 0.2 mol/L hydrochloric acid TS with water to make 1000 mL.

0.05 mol/L Hydrochloric acid TS Dilute 100 mL of 0.5 mol/L hydrochloric acid TS with water to make 1000 mL.

0.1 mol/L Hydrochloric acid TS Dilute 100 mL of 1 mol/L hydrochloric acid TS with water to make 1000 mL.

0.2 mol/L Hydrochloric acid TS Dilute 18 mL of hydro-
chloric acid with water to make 1000 mL.

0.5 mol/L Hydrochloric acid TS Dilute 45 mL of hydrochloric acid with water to make 1000 mL.

1 mol/L Hydrochloric acid TS Dilute 90 mL of hydrochloric acid with water to make 1000 mL.

2 mol/L Hydrochloric acid TS Dilute 180 mL of hydrochloric acid with water to make 1000 mL.

3 mol/L Hydrochloric acid TS Dilute 270 mL of hydrochloric acid with water to make 1000 mL.

5 mol/L Hydrochloric acid TS Dilute 450 mL of hydrochloric acid with water to make 1000 mL.

6 mol/L Hydrochloric acid TS Dilute 540 mL of hydrochloric acid with water to make 1000 mL.

7.5 mol/L Hydrochloric acid TS Dilute 675 mL of hydrochloric acid with water to make 1000 mL.

10 mol/L Hydrochloric acid TS Dilute 1000 mL of hydrochloric acid with water to make 1000 mL.

Hydrocotarnine C21H30O5 [Same as the namesake Hydrocortisone

Hydrocotarnine hydrochloride hydrate for assay See hydrocotarnine hydrochloride hydrate for assay.

Hydrocortamine hydrochloride hydrate for assay C12H15NO3.HCl.H2O [Same as the monograph Hydro-...
tals or crystalline powder.

**Identification**—Determine the infrared absorption spectrum according to the paste method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3300 cm⁻¹, 1690 cm⁻¹, 1600 cm⁻¹, 1307 cm⁻¹, 1232 cm⁻¹ and 760 cm⁻¹.

**Melting point** <2.60>: 203 – 206°C

**Purity** Clarity—Dissolve 1 g of 3-hydroxybenzoic acid in 20 mL of methanol; the solution is clear.

**Content:** not less than 99.0%. Assay—Weigh accurately about 0.2 g of 3-hydroxybenzoic acid, dissolve in 20 mL of diluted ethanol (95) (1 in 2), and titrate <2.50 with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of cresol red TS) until the color of the solution changes from yellow to dark orange-red. Perform a blank determination and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 13.81 mg of C₇H₆O₃

**p-Hydroxybenzoic acid** See parahydroxybenzoic acid.

**10-Hydroxy-2-(E)-decanoic acid for assay** 10-hydroxy-2-(E)-decanoic acid for thin-layer chromatography meeting the following additional specifications.

**Purity** Related substances—Dissolve 10 mg of 10-hydroxy-2-(E)-decanoic acid for assay in 100 mL of methanol, and use this solution as the standard solution. Pipet 1 mL of this solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak from both solutions by the automatic integration method: the total area of the peaks other than the peak of 10-hydroxy-2-(E)-decanoic acid from sample solution is not larger than the peak area of 10-hydroxy-2-(E)-decanoic acid from the standard solution.

**Operating conditions**

Detector, column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay under Royal Jelly.

Time span of measurement: About 4 times as long as the retention time of 10-hydroxy-2-(E)-decanoic acid beginning after the solvent peak.

**System suitability**

Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of 10-hydroxy-2-(E)-decanoic acid obtained from 10 μL of this solution is equivalent to 3.5 to 6.5% of that of 10-hydroxy-2-(E)-decanoic acid from 10 μL of the standard solution.

System performance and system repeatability: Proceed as directed in the system suitability in the Component determination under Royal Jelly.

**10-Hydroxy-2-(E)-decanoic acid for component determination** See 10-hydroxy-2-(E)-decanoic acid for assay

**10-Hydroxy-2-(E)-decanoic acid for thin-layer chromatography** C₁₀H₁₈O₃ White crystalline powder. Very soluble in methanol, freely soluble in ethanol (99.5), soluble in diethyl ether, and slightly soluble in water.

**Identification**—Determine the absorption spectrum of a solution of 10-hydroxy-2-(E)-decanoic acid for thin-layer chromatography in ethanol (99.5) (1 in 125,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits a maximum between 206 nm and 210 nm.

**Melting point** <2.60>: 63 – 66°C

**Purity** Related substances—Dissolve 5.0 mg of 10-hydroxy-2-(E)-decanoic acid for thin-layer chromatography in 1 mL of diethyl ether. Perform the test with 20 μL of this solution as directed in the Identification under Royal Jelly: no spot other than the principal spot at around Rf value of 0.5 appears.

**d-3-Hydroxy-cis-2,3-dihydro-5-[2-(dimethylamino)ethyl]-2-(4-methoxyphenyl)-1,5-benzothiazepine-4(5H)-one hydrochloride** C₂₀H₂₄N₂O₃S.HCl To 9 g of diltiazem hydrochloride add 50 mL of ethanol (99.5), and dissolve by heating at 80°C. To this solution add slowly 50 mL of a solution of potassium hydroxide in ethanol (99.5) (33 in 500) dropwise, and heat for 4 hours with stirring. Cool in an ice bath, filter, and evaporate the filtrate to dryness. Dissolve the residue in ethanol (99.5), add slowly a solution of hydrochloric acid in ethanol (99.5) (59 in 250) to make acidic, and filter. Add diethyl ether slowly to the filtrate, and filter the crystals produced. To the crystals add ethanol (99.5), heat to dissolve, add 0.5 g of activated charcoal, allow to stand, and filter. After cooling the filtrate in an ice-methanol bath, filter the crystals formed, and wash with diethyl ether. Further, add ethanol (99.5) to the crystals, and heat to dissolve. After cooling, filter the crystals produced, and dry under reduced pressure. White crystals or crystalline powder, having a slight, characteristic odor.

**Purity**—Dissolve 50 mg of d-3-hydroxy-cis-2,3-dihydro-5-[2-(dimethylamino)ethyl]-2-(p-methoxyphenyl)-1,5-benzothiazepine-4(5H)-one hydrochloride in chloroform to make exactly 10 mL, and use this solution as the sample solution. Perform the test with the sample solution as directed under Thin-layer Chromatography <2.03>. Spot 20 μL of the sample solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of ethanol (99.5), chloroform, water and acetic acid (100) (12:10:3:1) to a distance of about 13 cm, and air-dry the plate. Spray evenly iodine TS on the plate: any spot other than the principal spot does not appear.

**Water** <2.49>: not more than 1.0% (0.5 g).

**Content:** not less than 99.0%, calculated on the anhydrous basis. Assay—Weigh accurately about 0.5 g of d-3-hydroxy-cis-2,3-dihydro-5-[2-(dimethylamino)ethyl]-2-(p-methoxyphenyl)-1,5-benzothiazepine-4(5H)-one hydrochloride, dissolve in 2.0 mL of formic acid, add 60 mL of acetic anhydride, and titrate <2.50 with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L perchloric acid VS = 40.89 mg of C₂₀H₂₄N₂O₃S.HCl

**d-3-Hydroxy-cis-2,3-dihydro-5-[2-(dimethylamino)ethyl]-2-(p-methoxyphenyl)-1,5-benzothiazepine-4(5H)-one hydrochloride** See d-3-hydroxy-cis-2,3-dihydro-5-[2-(dimethylamino)ethyl]-2-(4-methoxyphenyl)-1,5-benzothiazepine-4(5H)-one hydrochloride.

**N-(2-Hydroxyethyl)isonicotinamide nitric ester** C₈H₁₄N₂O₄ A white crystalline powder.

**Identification**—Determine the infrared absorption spectrum of N-(2-hydroxyethyl)isonicotinamide nitric ester as di-
Hydroxylamine perchlorate-ethanol (99.5) TS

Dissolve 10 g of hydroxylammonium chloride in 20 mL of water, and add ethanol (95) to make 200 mL. To this solution add, with stirring, 150 mL of 0.5 mol/L potassium hydroxide-ethanol VS, and filter. Prepare before use.

Hydroxylamine TS, alkaline

Mix equal volumes of a solution of hydroxylammonium chloride in methanol (7 in 100) and a solution of sodium hydroxide in methanol (3 in 25), and filter. Prepare before use.

Hydroxylammonium chloride, pH 3.1

See hydroxylammonium chloride TS, pH 3.1.

Hydroxylammonium chloride hydrochloride TS

Acidify 100 mL of a solution of iron (III) chloride hexahydrate in ethanol (95) (1 in 200) with hydrochloric acid, and dissolve 1 g of hydroxylammonium chloride in the solution.

Hydroxylammonium chloride TS

Dissolve 20 g of hydroxylammonium chloride in water to make 65 mL, transfer it to a separator, add 2 to 3 drops of thymol blue TS, then add ammonia solution (28) until the solution exhibits a yellow color. Shake well after adding 10 mL of a solution of sodium N,N-diethyldithiocarbamate trihydrate (1 in 25), allow to stand for 5 minutes, and extract this solution with 10 to 15 mL portions of chloroform. Repeat the extraction until 5 mL of the extract does not exhibit a yellow color, upon adding 5 drops of a solution of copper (II) sulfate pentahydrate (1 in 100) and shaking it. Add 1 to 2 drops of thymol blue TS; add dropwise dilute hydrochloric acid to this aqueous solution until it exhibits a red color, then add water to make 100 mL.

Hydroxylammonium chloride TS, pH 3.1

Dispose 6.9 g of hydroxylammonium chloride in 80 mL of water, adjust the pH to 3.1 by adding dilute sodium hydroxide TS, and add water to make 100 mL.

Hydroxylamine perchlorate-ethanol (99.5) TS

Dilute 2.99 mL of hydroxylamine perchlorate TS with ethanol (99.5) to make 100 mL.

Storage—Preserve in tight containers, in a cold place.

Hydroxylamine perchlorate TS

An ethanol (99.5) solution which contains 13.4% of hydroxylamine perchlorate.

Storage—Preserve in tight containers, in a cold place.

Hydroxylamine TS

Dissolve 10 g of hydroxylammonium chloride in 20 mL of water, and add ethanol (95) to make 200 mL. To this solution add, with stirring, 150 mL of 0.5 mol/L potassium hydroxide-ethanol VS, and filter. Prepare before use.

Hydroxylamine TS, alkaline

Mix equal volumes of a solution of hydroxylammonium chloride in methanol (7 in 100) and a solution of sodium hydroxide in methanol (3 in 25), and filter. Prepare before use.

Hydroxylammonium chloride hydrochloride TS, pH 3.1

See hydroxylammonium chloride TS, pH 3.1.
retention time of capsaicin, the total area of the peaks other than 4-hydroxy-3-methoxybenzyl nonyl acid amide is not larger than the peak area of 4-hydroxy-3-methoxybenzyl nonyl acid amide from the standard solution.

3-(3-Hydroxy-4-methoxyphenyl)-2-(E)-propenyl acid

C₉H₁₀O₄ White to light yellow, crystals or crystalline powder. Sparingly soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: about 230°C (with decomposition).

**Identification**—Determine the absorption spectrum of a solution in methanol (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits maxima between 215 nm and 219 nm, between 238 nm and 242 nm, between 290 nm and 294 nm, and between 319 nm and 323 nm.

**Purity** Related substances—Dissolve 1 mg in 1 mL of methanol. Proceed the test with 2 μL of this solution as directed in the Identification (1) under Hochuekkito Extract: no spot other than the principle spot of around RI 0.6 appears.

3-(3-Hydroxy-4-methoxyphenyl)-2-(E)-propenyl acid (E)-ferulic acid TS for thin-layer chromatography

Dissolve 1 mg of 3-(3-hydroxy-4-methoxyphenyl)-2-(E)-propenyl acid and 1 mg of (E)-ferulic acid in 2 mL of methanol.

2-[4-(2-Hydroxymethyl)-1-piperazinyl] propanesulfonic acid

C₁₀H₁₉NO₄ White to light yellow crystals. Melting point: about 175°C (with decomposition).

**Purity** Related substances—Dissolve 0.5 mg of hypaconitine for purity in 1 mL of methanol, and use this solution as the sample solution. Pipet 0.2 mL of this solution, add methanol to make exactly 10 mL, and use this solution as the standard solution. Perform the test as directed under Thin-layer Chromatography <2.07>. Spot 5 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of chloroform, acetone and acetic acid (100) (7:2:1) to a distance of about 10 cm, and air-dry the plate. Splay evenly dilute sulfuric acid on the plate, and heat at 105°C for 10 minutes: the spots other than the principal spot at the RI value of about 0.3 obtained from the sample solution are not more intense than the spot from the standard solution.

**Hypaconitine for purity** C₁₁H₁₇NO₁₀ White, crystals or crystalline powder. Soluble in acetonitrile, sparingly soluble in ethanol (99.5) and in diethyl ether, and practically insoluble in water. Melting point: about 175°C (with decomposition).

**Identification**—Determine the infrared absorption spectrum of hypaconitine for purity as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3500 cm⁻¹, 1728 cm⁻¹, 1278 cm⁻¹, 1118 cm⁻¹, 1099 cm⁻¹ and 714 cm⁻¹.

**Absorbance** <2.24> E¹%cm (230 nm): 217 – 252 [5 mg dried for not less than 12 hours in a desiccator (reduced pressure not exceeding 0.67 kPa), phosphorus (V) oxide, 40°C], ethanol (99.5), 200 mL.

**Purity** Related substances—(1) Dissolve 5.0 mg of hypaconitine for purity in 2 mL of acetonitrile, and use as the sample solution. Pipet 1 mL of the sample solution, add acetonitrile to make exactly 50 mL, and use as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.07>. Spot 20 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography, and proceed the test as directed in the Identification in Processed Aconite Root: the spot other than the principal spot obtained with the sample solution is not more intense than the spot with the standard solution.

(2) Dissolve 5.0 mg of hypaconitine for purity in 5 mL of acetonitrile, and use as the sample solution. Pipet 1 mL of the sample solution, add acetonitrile to make exactly 50 mL, and use as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than the peaks of hypaconitine and the solvent obtained with the sample solution is not larger than the peak area of hypaconitine with the standard solu-
**Hypoxanthine**

*C5H4N4O* White crystals or crystalline powder. Freely soluble in ammonia TS, sparingly soluble in dilute hydrochloric acid and in hot water, very slightly soluble in water, and practically insoluble in methanol.

**Purity** Related substances—Dissolve 5.0 mg of hypoxanthine in 100 mL of a solution of ammonia solution (28) in methanol (1 in 10) to make exactly 100 mL. Proceed with this solution as directed in the Purity (4) under Mercaptopurine Hydrate: any spot other than the principal spot at the Rf value of about 0.2 does not appear.

**Content:** not less than 97.0% and not more than 103.0%.

**Assay**—Weigh accurately about 0.15 g of hypoxanthine, previously dried at 105°C for 3 hours, and dissolve in phosphate buffer solution, pH 7.0, to make exactly 1000 mL. Pipet 10 mL of this solution, and dilute with phosphate buffer solution, pH 7.0, to make exactly 250 mL. Read the absorbance *A* of this solution at the wavelength of 250 nm as directed under Ultraviolet-visible Spectrophotometry *C2.24* using phosphate buffer solution, pH 7.0, as the blank solution.

\[
\text{Amount (mg) of } C_5H_4N_4O = \frac{A}{779} \times 250,000
\]

**Ibuprofen** *C13H18O2* [Same as the namesake monograph]

**Icariin for thin-layer chromatography** *C21H20O12* Light yellow crystals. Very slightly soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: about 234°C (with decomposition).

**Imidazole** *C3H4N2* White crystalline powder. Very soluble in water and in methanol.

**Melting point** *C2.60*: 89 – 92°C

**Absorbance** *C2.24*: *E*<sub>1% 1cm</sub> (313 nm): not more than 0.031 (8 g, water, 100 mL).

**Imidazole for Karl Fischer method** See the Water Determination *C2.48*.

**Imidazole for thin-layer chromatography** *C3H4N2* White, crystalline powder. Very soluble in water and in methanol, and freely soluble in ethyl acetate and in dichloromethane.

**Melting point** *C2.60*: 89 – 92°C

**Purity** Related substances—Dissolve 10 mg of imidazole for thin-layer chromatography in exactly 20 mL of dichloromethane, and proceed with this solution as directed in the Purity (6) under Clotrimazole: any spot other than the principal spot does not appear.

**Imidazole TS** Dissolve 8.25 g of imidazole in 65 mL of water, adjust the pH to 6.8 with 5 mol/L hydrochloric acid TS, and add water to make 100 mL.

**Imidobenzyl** *C8H13N* White to light brown crystals or crystalline powder, having a slight, characteristic odor.

**Melting point** *C2.60*: 104 – 110°C

**Purity** (1) Clarity of solution—Dissolve 1.0 g of imidobenzyl in 20 mL of methanol by heating on a water bath: the solution is clear.

(2) Related substances—Proceed as directed in the Purity (6) under Carbamazepine: any spot other than the principal spot at the Rf value of about 0.9 does not appear.

**Nitrogen** *C1.08*: 6.8 – 7.3%.
2,2'-Iminodiethanol hydrochloride C₆H₁₃NO₂.HCl
A pale yellow liquid.
*Refractive index* <2.45> n₀₂ = 1.515 - 1.519
*Specific gravity* <2.56> d₅₀ = 1.259 - 1.263
*Water* <2.48>: less than 0.1%.

Imipramine hydrochloride C₁₈H₂₁N₂.HCl [Same as the namesake monograph]

Indigo carmine C₁₈H₂₃Na₂O₄S₂ [K 8092, Special class]

Indigo carmine TS Dissolve 0.20 g of indigo carmine in water to make 100 mL. Use within 60 days.

2,3-Indolinedione C₈H₇NO₂ [K 8089, Special class]

Indometacin C₁₉H₁₆ClNO₄ [Same as the namesake monograph]

Insulin human [Same as the monograph Insulin Human (Genetical Recombination)]

Interleukin-2 dependent mouse natural killer cell (NKC3)
Fractionate using discontinuous concentration gradient method cells obtained by removing adhesive cells and phagocyteic cells from C3H/He mouse spleen cells. Then, cultivate in soft agar containing interleukin-2 the cell fraction with potent NK activity and obtain the colonies. From the cell lines obtained, one of the cell lines dependent on interleukin-2 that grows in liquid medium and serially subcultured in liquid medium containing interleukin-2 is identified as NKC3.

Iodine 1 [K 8920, Special class]

Iodine for assay I [Same as the monograph Iodine]

Iodine monobromide IBr Blackish brown crystals or masses. It dissolves in water, in ethanol (95), in diethyl ether, in carbon disulfide and in acetic acid (100).
*Melting point* <2.60>: 40°C
*Storage*—Preserve in light-resistant glass containers, in a cold place.

Iodine-starch TS To 100 mL of starch TS add 3 mL of dilute iodine TS.

Iodine trichloride ICl₃ [K 8403, Special class]

Iodine TS Dissolve 14 g of iodine in 100 mL of a solution of potassium iodide (2 in 5), add 1 mL of dilute hydrochloric acid, and dilute with water to make 1000 mL (0.05 mol/L).
*Storage*—Preserve in light-resistant containers.

Iodine TS, dilute To 1 volume of iodine TS add 4 volumes of water.

0.002 mol/L Iodine TS Measure exactly 1 mL of 0.5 mol/L iodine TS, add water to make exactly 250 mL, pipet 10 mL of the solution, and add water to make exactly 100 mL. Prepare before use.

0.5 mol/L Iodine TS To 12.7 g of iodine and 25 g of potassium iodide add 10 mL of water, triturate, and add water to make 100 mL.

Iodoethane C₂H₃I A colorless or a dark-brown, clear liquid, having diethyl ether-like odor.
*Distilling range* <2.57>: 71.0 - 72.5°C, not less than 94 vol%.

Iodomethane CH₃I [K 8919, Special class]

Iodomethane for assay CH₃I Clear, colorless liquid. On exposure to light, it liberates iodine and becomes brown. Miscible with ethanol (95) and with diethyl ether, and sparingly soluble in water. Use the distillate obtained between 42.2°C and 42.6°C.
*Specific gravity* <2.56> d₅₀: 2.27 - 2.28.

Purity—Perform the test with 1 µL of iodomethane for assay as directed under Gas Chromatography according to the operating conditions in the Assay under Hypromellose. Measure each peak area by the automatic integration method, and calculate the amount of iodomethane by the area percentage method: it shows the purity of not less than 99.8%. Adjust the detection sensitivity so that the peak height of iodomethane from 1 µL of methyl iodide for assay is about 80% of the full scale.
*Content*: not less than 98.0%. Assay—Proceed as directed in the Assay under Isopropyl iodide for assay.

Each mL of 0.1 mol/L silver nitrate VS = 14.19 mg of CH₃I

5-Iodouracil for liquid chromatography C₁₉H₁₅N₃O₂
White, crystalline powder. Melting point: about 275°C (with decomposition).

Purity—Dissolve 3 mg of 5-iodouracil for liquid chromatography in a mixture of diluted methanol (1 in 25) to make 10 mL. Perform the test with 10 µL of this solution as directed under Liquid Chromatography according to the operating conditions in the Purity under Idoxuridine Eye Drops. Measure each peak area by the automatic integration method over a time span of twice as long as the retention time of the principal peak, and calculate the amount of 5-iodouracil by the area percentage method: It shows the purity of not less than 98.5%.
*Content*: not less than 98.5%. Assay—Weigh accurately about 5 mg of 5-iodouracil for liquid chromatography, previously dried at 60°C for 3 hours under reduced pressure, dissolve in water to make exactly 250 mL. Perform the test with this solution as directed under Ultraviolet-visible Spectrophotometry, and determine the absorbance A at the wavelength of maximum absorption at about 282 nm.

Amount (mg) of 5-iodouracil (C₁₉H₁₅N₃O₂)

\[ A \times 265 \times 2500 \]

Iotalamic acid for assay C₁₁H₁₃I₃N₂O₇ [Same as the monograph Totalamic Acid]

Iron Fe Iron in the forms of strips, sheets, granules or wires. Fe: not less than 97.7%. It is attracted by a magnet.

Iron (II) sulfate heptahydrate FeSO₄·7H₂O [K 8978, Special class]

Iron (II) sulfate TS Dissolve 8 g of iron (II) sulfate heptahydrate in 100 mL of freshly boiled and cooled water. Prepare before use.

Iron (II) sulfide FeS [K 8948, for hydrogen sulfide development]

Iron (II) tartrate TS Dissolve 1 g of iron (II) sulfate heptahydrate, 2 g of potassium sodium tartrate tetrahydrate and 0.1 g of sodium hydrogen sulfite in water to make 100 mL.
Iron (II) thiocyanate TS  Add 3 mL of dilute sulfuric acid to 35 mL of water, and remove the dissolved oxygen by boiling the solution. Dissolve 1 g of iron (II) sulfate heptahydrate in this hot solution, cool, and then dissolve 0.5 g of potassium thiocyanate. When the solution is pale red in color, decolorize by adding reduced iron, separate the excess of reduced iron by decanting, and preserve the solution with protection from oxygen. Do not use a solution showing a pale red color.

Iron (II) trisodium pentacyanoferrate (III) dihydrate TS  Add 0.012 g of sodium pentacyanonitrosylferrate (III) to 2.3 mL of ammonia water, shake, stopper closely, and allow to stand in a refrigerator overnight. Add this solution to 10 mL of ethanol (99.5), filter a yellow colored precipitate by suction, wash with ether (99.5), dry, and preserve in a desiccator. Before using, dissolve in water to make a solution of 1.0 mg/mL, and store in a refrigerator. Use within 7 days after preparation.

Iron (III) chloride-acetic acid TS  Dissolve 0.1 g of iron (III) chloride hexahydrate in diluted acetic acid (3 in 100) to make 100 mL.

Iron (III) chloride hexahydrate  
FeCl₃·6H₂O  [K 8142, Special class]

Iron (III) chloride-Iodine TS  Dissolve 5 g of iron (III) chloride hexahydrate and 2 g of iodine in a mixture of 50 mL of acetone and 50 mL of a solution of tartaric acid (1 in 5).

Iron (III) chloride-methanol TS  Dissolve 1 g of iron (III) chloride hexahydrate in methanol to make 100 mL.

Iron (III) chloride-potassium hexacyanoferrate (III) TS  Dissolve 0.1 g of potassium hexacyanoferrate (III) in 20 mL of iron (III) chloride TS. Prepare before use.

Iron (III) chloride-pyridine TS, anhydrous  Heat gradually 1.7 g of iron (III) chloride hexahydrate by direct application of flame, melt, and solidify. After cooling, dissolve the residue in 100 mL of chloroform, add 8 mL of pyridine, and filter.

Iron (III) chloride TS  Dissolve 9 g of iron (III) chloride hexahydrate in water to make 100 mL (1/3 mol/L).

Iron (III) chloride TS, acidic  To 60 mL of acetic acid (100) add 5 mL of sulfuric acid and 1 mL of iron (III) chloride hexahydrate.

Iron (III) chloride TS, dilute  Dilute 2 mL of iron (III) chloride hexahydrate TS with water to make 100 mL. Prepare before use.

Iron (III) nitrate enehydrate  
Fe(NO₃)₃·9H₂O  [K 8559, Special class]

Iron (III) nitrate TS  Dissolve 1 g of iron (III) nitrate enehydrate in hydrochloric acid-potassium chloride buffer solution (pH 2.0) to make 300 mL.

Iron (III) perchlorate-ethanol TS  Dissolve 0.8 g of iron (III) perchlorate hexahydrate in perchloric acid-ethanol TS to make 100 mL.

Storage—Preserve in tight containers, in a cold place.

Iron (III) perchlorate hexahydrate  
Fe(ClO₄)₃·6H₂O  Hygroscopic, light purple crystals, and a solution in ethanol (99.5) (1 in 125) is clear and orange in color.
Isoniazid (C\textsubscript{6}H\textsubscript{7}N\textsubscript{3}O). For assay, dissolve 0.1 g of isoniazid in a mixture of 50 mL of methanol and 0.12 mL of hydrochloric acid, and add methanol to make 200 mL.

**Isonicotinic acid** White, crystals or powder. Melting point: about 315°C (decomposition).

**Isonicotinic acid amide** C\textsubscript{6}H\textsubscript{5}N\textsubscript{2}O White, crystals or crystalline powder.

**Isobutyl parahydroxybenzoate** C\textsubscript{11}H\textsubscript{14}O\textsubscript{3} Colorless, clear liquid, odorless. Freely soluble in water, in ethanol (95) and in chloroform, and practically insoluble in water.

Melting point 2\textsubscript{2.60}°: 75 – 77°C
Residue on ignition 2\textsubscript{2.44}°: not more than 0.1%.
Content: not less than 98.0%. Assay—Proceed as directed in the Assay under Ethyl Parahydroxybenzoate.

Isobutyl salicylate C\textsubscript{17}H\textsubscript{20}N\textsubscript{2}S.HCl White, odorless, crystalline powder. Odorless. Freely soluble in water, in ethanol (95), in acetone and in diethyl ether, and practically insoluble in water.

Column: A column about 3 mm in inside diameter and about 2 m in length, packed with siliceous earth for gas chromatography, about 2 m in length, packed with siliceous earth for gas chromatography, 180 to 250 \(\mu\)m in particle diameter, coated with polyethylene glycol 20 M for gas chromatography at the ratio 4:1.

Dissolve 0.02 to 0.05 mg of cytochrome C, trypsinogen, lentil-lectin basic band, lentil-lectin acidic band, horse myoglobin basic band, horse myoglobin acidic band, b-lactoglobulin A, in 0.1 mL of saccharose solution (3 in 10).

**Isopropyl 4-aminobenzoate** NH\textsubscript{2}C\textsubscript{6}H\textsubscript{4}COOCH(CH\textsubscript{3})\textsubscript{2}

Pale brown crystals.

Melting point 2\textsubscript{2.60}°: 83 – 86°C

**Isopropyl benzoate** C\textsubscript{6}H\textsubscript{5}COOCH(CH\textsubscript{3})\textsubscript{2} A clear, colorless liquid, having a characteristic odor.

**Isopropylamine-ethanol TS** To 20 mL of isopropylamine add ethanol (99.5) to make 100 mL. Prepare before use.

**Isopropylamine-ethanol TS** To 20 mL of isopropylamine add ethanol (99.5) to make 100 mL. Prepare before use.

**Isoniazid** C\textsubscript{6}H\textsubscript{7}N\textsubscript{3}O White, crystals or powder. Melting point: about 315°C (decomposition).

**Isonicotinic acid amide** C\textsubscript{6}H\textsubscript{5}N\textsubscript{2}O

White, crystals or powder.

**Isopropyl benzoate** C\textsubscript{6}H\textsubscript{5}COOCH(CH\textsubscript{3})\textsubscript{2} A clear, colorless liquid, having a characteristic odor.

**Isopropylamine-ethanol TS** To 20 mL of isopropylamine add ethanol (99.5) to make 100 mL. Prepare before use.

**Isoniazid** C\textsubscript{6}H\textsubscript{7}N\textsubscript{3}O

White, crystals or powder. Melting point: about 315°C (decomposition).

**Isopropyl benzoate** C\textsubscript{6}H\textsubscript{5}COOCH(CH\textsubscript{3})\textsubscript{2} A clear, colorless liquid, having a characteristic odor.

**Isopropylamine-ethanol TS** To 20 mL of isopropylamine add ethanol (99.5) to make 100 mL. Prepare before use.

**Isoniazid** C\textsubscript{6}H\textsubscript{7}N\textsubscript{3}O

White, crystals or powder. Melting point: about 315°C (decomposition).

**Isonicotinic acid amide** C\textsubscript{6}H\textsubscript{5}N\textsubscript{2}O

White, crystals or powder.

**Isopropyl benzoate** C\textsubscript{6}H\textsubscript{5}COOCH(CH\textsubscript{3})\textsubscript{2} A clear, colorless liquid, having a characteristic odor.

**Isopropylamine-ethanol TS** To 20 mL of isopropylamine add ethanol (99.5) to make 100 mL. Prepare before use.

**Isoniazid** C\textsubscript{6}H\textsubscript{7}N\textsubscript{3}O

White, crystals or powder. Melting point: about 315°C (decomposition).

**Isonicotinic acid amide** C\textsubscript{6}H\textsubscript{5}N\textsubscript{2}O

White, crystals or powder.

**Isopropyl benzoate** C\textsubscript{6}H\textsubscript{5}COOCH(CH\textsubscript{3})\textsubscript{2} A clear, colorless liquid, having a characteristic odor.

**Isopropylamine-ethanol TS** To 20 mL of isopropylamine add ethanol (99.5) to make 100 mL. Prepare before use.
Specific gravity <2.56> d 15°: 1.700 – 1.710

Purity—Perform the test with 1 μL of isopropyl iodide for assay as directed under Gas Chromatography <2.02> according to the operating conditions in the Assay under Hypromellose. Measure each peak area by the automatic integration method, and calculate the amount of isopropyl iodide by the area percentage method: It shows the purity of not less than 99.8%. Adjust the detection sensitivity so that the peak height of isopropyl iodide from 1 μL of isopropyl iodide for assay is about 80% of the full scale.

Content: not less than 98.0%. Assay—Transfer 10 mL of ethanol (95) into a brown volumetric flask, weigh accurately, add 1 mL of isopropyl iodide for assay, and weigh accurately again. Add ethanol (95) to make exactly 100 mL, pipet 20 mL of this solution into the second brown volumetric flask, add exactly 50 mL of 0.1 mol/L silver nitrate VS and then 2 mL of nitric acid, stopper, shake occasionally for 2 hours in a dark place, and allow to stand overnight in a dark place. Shake occasionally for 2 hours, add water to make exactly 100 mL, and filter through dry filter paper. Discard the first 20 mL of the filtrate, pipet the next 50 mL, make exactly 100 mL, and filter through dry filter paper. Add 2 mL of nitric acid, stopper, shake occasionally for 2 hours, add water to make exactly 100 mL, and filter through dry filter paper. Discard the first 20 mL of the filtrate, pipet the next 50 mL, and titrate <2.50> the excess silver nitrate with 0.1 mol/L ammonium thiocyanate VS (indicator: 2 mL of ammonium iron (III) sulfate TS). Perform a blank determination in the same manner.

Each mL of 0.1 mol/L silver nitrate VS = 17.00 mg of C 3 H 1 I

Isopropyl myristate C 17 H 35 O 2 Colorless, clear, oily liquid, and odorless. Congeals at about 5°C. Soluble in 90% alcohol, miscible with many organic solvents and with solid oils, and insoluble in water, in glycerin and in propylene glycol.

Refractive index <2.45> n D 20: 1.432 – 1.436
Specific gravity <2.56> d 15°: 0.846 – 0.854
Saponification value <1.13>: 202 – 212
Acid value <1.13>: not more than 1.
Iodine value <1.13>: not more than 1.
Residue on ignition <2.44>: not more than 0.1% (1 g).

Isopropyl myristate for sterility test C 17 H 35 O 2 Transfer 100 mL of isopropyl myristate into a centrifuge tube, add 100 mL of twice-distilled water, and shake vigorously for 10 minutes. Then centrifuge at a rate of 1800 revolutions per minute for 20 minutes, separate the supernatant liquid (isopropyl myristate layer), and determine the pH of the residual water layer: not less than 5.5.

Treat isopropyl myristate which meets the requirements of pH determination as follows: 500 mL of isopropyl myristate, which has met the requirements of pH determination, is percolated through a 15-cm high layer of activated alumina filled in a glass column 20 mm in diameter and 20 cm in length with a slightly positive pressure in order to facilitate adequate flow, and then sterilized by filtration.

Isopropyl parahydroxybenzoate C 10 H 12 O 3 Odorless and colorless fine crystals, or white, crystalline powder. Freely soluble in ethanol (95), in acetone and in diethyl ether, and very slightly soluble in water.

Melting point <2.60>: 84 – 86°C
Residue on ignition <2.44>: not more than 0.1%

Content: not less than 99.0%. Assay—Proceed as directed in the Assay under Ethyl Parahydroxybenzoate.

Each mL of 1 mol/L sodium hydroxide VS = 180.2 mg of C 6 H 12 O 6

4-Isopropylphenol C 8 H 14 O White to reddish yellow, crystals or crystalline powder.

Melting point <2.60>: 59 – 63°C

Isosorbide dinitrate for assay C 6 H 8 N 2 O 8 [Same as the monograph Isosorbide Dinitrate. It contains not less than 99.0% of isosorbide dinitrate (C 6 H 8 N 2 O 8) meeting the following additional specifications.]

Purity Related substances—Dissolve 50 mg of isosorbide dinitrate for assay in 50 mL of a mixture of water and methanol (1:1), and use this solution as the sample solution. Pipet 1 mL of this solution, add a mixture of water and methanol (1:1) to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine each peak area of both solutions by the automatic integration method: the total area of the peaks other than the peak of isosorbide dinitrate obtained from the sample solution is not larger than the peak area of isosorbide dinitrate from the standard solution.

Operating conditions
Detector, column, column temperature, mobile phase and flow rate: Proceed as directed in the operating procedures in the Assay under Isosorbide Dinitrate Tablets.

Time span of measurement: About 2 times as long as the retention time of isosorbide dinitrate beginning after the solvent peak.

System suitability
Test for required detectability: Pipet 5 mL of the standard solution, and add a mixture of water and methanol (1:1) to make exactly 50 mL. Confirm that the peak area of isosorbide dinitrate obtained from 10 μL of this solution is equivalent to 7 to 13% of that of isosorbide dinitrate from 10 μL of the standard solution.

System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of isosorbide dinitrate are not less than 3000 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of isosorbide dinitrate is not more than 2.0%.

Isotonic sodium chloride solution [Same as the namesake monograph]

Isosuprine hydrochloride for assay C 18 H 23 NO 3 .HCl [Same as the monograph Isosuprine Hydrochloride]

Japanese acid clay Natural hydrous aluminum silicate, grayish white powder, having a particle size of about 74 μm.

Loss on drying <2.41>: not more than 10% (1 g, 105°C, 4 hours).

Water adsorbing capacity: not less than 2.5%. Weigh accurately about 10 g of Japanese acid clay in weighing bottle, allow to stand for 24 hours with cover in a chamber, in which humidity is maintained to 80% by means of sulfuric acid (specific gravity 1.19), reweigh, and determine the increase of mass of the sample.

Jesaconitine for purity C 42 H 49 NO 12 A white powder.
Freely soluble in acetonitrile, in ethanol (99.5) and in diethyl ether, and practically insoluble in water.

Identification—Determine the infrared absorption spectrum of jesaconitine for purity as directed in the potassium bromide disk method under Infrared Spectrophotometry 2.25. It exhibits absorption at the wave numbers of about 3150 cm\(^{-1}\), 875 cm\(^{-1}\), 1715 cm\(^{-1}\), 1607 cm\(^{-1}\), 1281 cm\(^{-1}\), 1259 cm\(^{-1}\), 1099 cm\(^{-1}\) and 772 cm\(^{-1}\).

Absorbance is equivalent to 3.5 to 6.5 m\(^{-1}\) for not less than 12 hours in a desiccator (reduced pressure not exceeding 0.67 kPa, phosphorus (V) oxide, 40°C), coulometric titration].

Josamycin \(\text{C}_{26}\text{H}_{28}\text{Cl}_{2}\text{N}_{4}\text{O}_{4}\) [Same as the namesake monograph]

Josamycin propionate \(\text{C}_{26}\text{H}_{27}\text{O}_{16}\) [Same as the namesake monograph]

Kainic acid See kainic acid hydrate.

Kainic acid for assay See kainic acid hydrate.

Kainic acid hydrate \(\text{C}_{10}\text{H}_{15}\text{NO}_{4}\text{H}_{2}\text{O}\) [Same as the namesake monograph]

Kainic acid hydrate for assay See kainic acid hydrate.

Kanamycin sulfate \(\text{C}_{18}\text{H}_{33}\text{N}_{2}\text{O}_{11} \cdot \text{H}_{2}\text{SO}_{4}\) [Same as the namesake monograph]

Karl Fischer TS See Water Determination 2.48.

Kerosene It is mainly a mixture of hydrocarbons in the methane series, and a colorless, clear liquid, having not a disagreeable, characteristic odor.

Specific gravity is about 0.80.

Distilling range is 180 – 300°C.

Ketoconazole \(\text{C}_{26}\text{H}_{28}\text{Cl}_{2}\text{N}_{4}\text{O}_{3}\) [Same as the namesake monograph]

Ketoconazole for assay \(\text{C}_{26}\text{H}_{28}\text{Cl}_{2}\text{N}_{4}\text{O}_{3}\) [Same as the monograph Ketoconazole.

Kininogen Produced by purifying from bovine plasma. Dissolve an appropriate amount of kininogen in 0.02 mol/L phosphate buffer solution, pH 8.0 so that 10 mL of the solution contains 1 mg of kininogen, and use this solution as the sample solution. Perform the following tests with the sample solution: it meets the requirement of each test.

(i) Immediately after the sample solution is prepared, add 0.1 mL of a solution of trichloroacetic acid (1 in 5) to 0.5 mL of the sample solution, shake, and centrifuge. To 0.5 mL of the supernatant liquid add 0.5 mL of gelatin-tris buffer solution, pH 8.0, and shake. To 0.1 mL of this solution add 1.9 mL of gelatin-tris buffer solution. Proceed with 0.1 mL of this solution as directed in the Purity (2) under Kallidinogenase, and determine the amount of kinin: kinin is not detected.

(ii) Warm 0.5 mL of the sample solution at 30 ± 0.5°C for 20 minutes, and proceed as directed in (i): kinin is not detected.

(iii) Perform the test with 0.5 mL of the sample solution as directed in the Purity (2) under Kallidinogenase: the decomposition of bradykinin is not observed.

(iv) To 0.5 mL of the sample solution add 0.5 mL of 0.02 mol/L phosphate buffer solution, pH 8.0 containing 500 μg of crystalline trypsin, previously warmed at 30 ± 0.5°C for 5 minutes, warm this solution at 30 ± 0.5°C for 5 minutes, add 0.2 mL of a solution of trichloroacetic acid (1 in 5), and shake. Then boil for 3 minutes, cool in ice immediately, and centrifuge. To 0.5 mL of the supernatant liquid add 0.5 mL of gelatin-tris buffer solution, pH 8.0, and shake. To 0.1 mL of this solution add 0.9 mL of trichloroacetic acid-gelatin-tris buffer solution. To 0.1 mL of this solution add trichloroacetic acid-gelatin-tris buffer solution to
make 20 mL, then proceed as directed in (i), and determine the amount, \( B_k \), of kinin per well. Calculate the kinin-releasing activity per mg by the following equation: not less than 10 \( \mu g \) bradykinin equivalent per mg.

\[
\text{Kinin-releasing activity per mg (\( \mu g \) bradykinin equivalent/mg)} = \frac{B_k}{0.0096}
\]

**Kininogen TS** Dissolve a sufficient quantity of kininogen in 0.02 mol/L phosphate buffer solution, pH 8.0 to prepare a solution having an ability in each mL to release kinin corresponding to not less than 1 \( \mu g \) of bradykinin.

**Labetalol hydrochloride** \( C_{19}H_{24}N_2O_3\cdot HCl \) [Same as the namesake monograph]

**Labetalol hydrochloride for assay** \( C_{19}H_{24}N_2O_3\cdot HCl \) [Same as the monograph Labetalol Hydrochloride. However, when dried, it contains not less than 99.0% of labetalol hydrochloride (\( C_{19}H_{24}N_2O_3\cdot HCl \)).]

**Lactic acid** \( CH_3CH(OH)COOH \) [K 8726, Special class]

**Lactic acid TS** Dissolve 12.0 g of lactic acid in water to make 100 mL.

**Melting point** \( <2.60^\circ C \): not less than 118°C

**Purity**—Dissolve 0.10 g of lactic acid in 10 mL of a mixture of methanol and water (3:2), and perform the test with 10 \( \mu L \) of this solution as directed in the Identification (2) under Erythromycin Lactobionate: the spot other than the principal spot is not found.

**\( \beta \)-Lactoglobulin** Prepare from milk. White to light yellow powder.

\[ \text{Nitrogen content} <1.08\% : \text{not less than 14\% (calculated on the dried basis)} \]

**Lactose** See lactose monohydrate.

**\( \alpha \)-Lactalbumin** White powder. Derived from milk. Molecular weight of about 14,200.

**Lactobionic acid** \( C_{12}H_{22}O_12 \) Colorless crystals or white crystalline powder, having no odor.

\[ \text{Melting point} <2.25^\circ C \: \text{to} \: 118^\circ C \]

**Purity**—Dissolve 0.10 g of lactobionic acid in 10 mL of a mixture of methanol and water (3:2), and perform the test with 10 \( \mu L \) of this solution as directed in the Identification (2) under Erythromycin Lactobionate: the spot other than the principal spot is not found.

**Lactose monohydrate** \( C_{12}H_{22}O_{11} \cdot H_2O \) [Same as the monograph Lactose].

**Lactose substrate TS** Dissolve 6.0 g of lactose monohydrate in diluted disodium hydrogen phosphate-citric acid buffer solution, pH 4.5 (1 in 10) to make 100 mL.

**Lactose substrate TS for \( \beta \)-galactosidase (penicillium)** Dissolve 6.0 g of lactose monohydrate in diluted disodium hydrogen phosphate-citric acid buffer solution, pH 4.5 (1 in 10) to make 100 mL.

**Lanthanum-alizarin complexone TS** To 1 mL of ammonia water (28) add 10 mL of water. To 4 mL of this solution add 4 mL of a solution of ammonium acetate (1 in 5) and 192 mg of alizarin complexone, and label this solution as alizarin complexone stock solution. Dissolve 41 g of sodium acetate trihydrate in 400 mL of water, and add 24 mL of acetic acid (100). To this solution add the total volume of the alizarin complexone stock solution, add 400 mL of acetone, and label this solution as alizarin complexone solution. To 10 mL of diluted hydrochloric acid (1 in 6) add 163 mg of lanthanum (III) oxide, heat to dissolve, and label this solution as lanthanum solution. To the alizarin complexone solution add the lanthanum solution, and mix. After cooling, adjust to pH 4.7 with acetic acid (100) or ammonia water (28), and add water to make 1000 mL. Prepare before use.

**Lanthanum chloride TS** To 58.65 g of lanthanum (III) oxide add 100 mL of hydrochloric acid, and boil. After cooling, add water to make 1000 mL.

**Lanthanum (III) oxide** \( La_2O_3 \) White crystals.

\[ \text{Loss on ignition} <2.43\% : \text{not more than 0.5\% (1 g, 1000°C, 1 hour)} \]

**Lauromacrogol** [Same as the namesake monograph]

**Lead acetate** See lead (II) acetate trihydrate.

**Lead acetate TS** See lead (II) acetate TS.

**Lead monoxide** See lead (II) oxide.

**Lead nitrate** See lead (II) nitrate.

**Lead dioxide** See lead (IV) oxide.

**Lead subacetate TS** Place the yellowish mixture, obtained by triturating 3 g of lead (II) acetate trihydrate and 1 g of lead (II) oxide with 0.5 mL of water, in a beaker, and heat on a water bath, covering with a watch glass, until it shows a homogeneous, white to reddish white color. Then add 9.5 mL of hot water in small portions, cover it again with a watch glass, and set it aside. Decant the supernatant liquid, and adjust the specific gravity to 1.23 to 1.24 (15°C) by adding water. Preserve in tightly stoppered bottles.

**Lead subacetate TS, dilute** To 2 mL of lead subacetate TS add freshly boiled and cooled water to make 100 mL. Prepare before use.

**Lead (II) acetate trihydrate** \( Pb(CH_3COO)_2 \cdot 3H_2O \) [K 8374, Special class]

**Lead (II) acetate** To 9.5 g of lead (II) acetate trihydrate add freshly boiled and cooled water to make 100 mL. Preserve in tightly stoppered bottles (0.25 mol/L).

**Lead (II) nitrate** \( Pb(NO_3)_2 \) [K 8563, Special class]
Levothyroxine sodium hydrate for thin-layer chromatography

- A supernatant liquid of a solution in dilute acetic acid (1 in 100) responds to Quality Tests (1-09) (3) for lead salt.
- Leucine $\text{C}_9\text{H}_{19}\text{NO}_2$ [Same as the namesake monograph]
- Leucine for assay $\text{C}_9\text{H}_{19}\text{NO}_2$ [Same as the monograph 1-Leucine. When dried, it contains not less than 99.0% of 1-Leucine ($\text{C}_9\text{H}_{19}\text{NO}_2$).]
- Levallorphan tartrate for assay $\text{C}_{17}\text{H}_{25}\text{NO}_2\cdot\text{C}_4\text{H}_6\text{O}_6$ [Same as the monograph Levallorphan Tartrate. When dried, it contains not less than 99.0% of $\text{C}_{17}\text{H}_{25}\text{NO}_2\cdot\text{C}_4\text{H}_6\text{O}_6$.]
- Levothyroxine sodium See levothyroxine sodium hydrate.
- Levothyroxine sodium for thin-layer chromatography
  See levothyroxine sodium hydrate for thin-layer chromatography.
- Levothyroxine sodium hydrate $\text{C}_{19}\text{H}_{25}\text{NO}_2\cdot\text{C}_4\text{H}_6\text{O}_6$ [Same as the namesake monograph]
- Levothyroxine sodium hydrate for thin-layer chromatography $\text{C}_{19}\text{H}_{25}\text{NO}_2\cdot\text{C}_4\text{H}_6\text{O}_6$ [Same as the monograph Levothyroxine Sodium Hydrate. Proceed the test as directed in the Identification (3) under Levothyroxine Sodium Hydrate.]
- Limonene $\text{C}_{10}\text{H}_{16}$ Clear and colorless liquid, having a characteristic odor.
  - Refractive index $<2.45$ $n^p_{D} = 1.427 - 1.474$
  - Specific gravity $<2.56$ $d^p_{20} = 0.841 - 0.846$
  - Melting point $<2.60^\circ$: 176 - 177°C
- Purity Related substances—Dissolve 0.1 g of limonene in 25 mL of hexane and use this solution as the sample solution. Perform the test with 2 $\mu$L of the sample solution as directed under Gas Chromatography (2.02) according to the following conditions. Measure each peak area by the automatic integration method and calculate the amount of limonene: it is not less than 97.0%.
- Operating conditions
  Proceed the operating conditions in the Assay under Eucalyptus Oil except detection sensitivity and time span of measurement.
  - Detection sensitivity: Measure 1 $\mu$L of limonene, add hexane to make 100 $\mu$L, and adjust the detection sensitivity so that the peak height of limonene obtained from 2 $\mu$L of this solution is 40% to 60% of the full scale.
  - Time span of measurement: About 3 times as long as the retention time of limonene beginning after the solvent peak.
- Limonin for thin-layer chromatography $\text{C}_{26}\text{H}_{30}\text{O}_8$
  White crystals or crystalline powder. Slightly soluble in methanol and in ethyl acetate, and practically insoluble in water and in ethanol (99.5). Melting point: about 290°C.
- Identification Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared-visible Spectrophotometry (2.22): it exhibits absorption at the wave numbers of about 1759 cm$^{-1}$, 1709 cm$^{-1}$, 1166 cm$^{-1}$, 798 cm$^{-1}$ and 601 cm$^{-1}$.
- Purity Related substances—Dissolve 1 mg of limonin for thin-layer chromatography in 1 mL of ethyl acetate, and perform the test with 1 $\mu$L of this solution as directed in the Identification (2) under Orenge dokuto Extract: no spot other than the principal spot ($R_f$ value is about 0.4) appears.
- (Z)-Ligustilide for thin-layer chromatography $\text{C}_{12}\text{H}_{14}\text{O}_2$
  A clear, yellow-grown liquid, having a characteristic odor. Miscible with methanol and with ethanol (99.5), and practically insoluble in water.
- Identification—Determine the absorption spectrum of a solution in methanol (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry (2.24): it exhibits a maximum between 320 nm and 324 nm.
- Purity Related substances—Dissolve 1 mg in 10 mL of methanol. Proceed the test with 1 $\mu$L of this solution as directed in the Identification (5) under Hochuekikuto Exctract: no spot other than the principle spot of around $R_f$ 0.6 appears.
- Lithrothyroline sodium $\text{C}_{10}\text{H}_{13}\text{I}_3\text{NaO}_4$ [Same as the namesake monograph]
- Lithrothyroline sodium for thin-layer chromatography
  See Lithrothyroline Sodium. Proceed as directed for the Identification (1) under Lithrothyroline Sodium Tablets: any spot other than the principal spot at the $R_f$ value of 0.3 to 0.4 does not appear.
- Liquid paraffin See paraffin, liquid.
- Liquiritin for thin-layer chromatography $\text{C}_{17}\text{H}_{20}\text{O}_9$ A clear, yellow-grown liquid, having a characteristic odor. Miscible with methanol and with ethanol (99.5), and practically insoluble in water. Melting point: about 210°C (with decomposition).
- Identification—Determine the absorption spectrum of a solution in dilute acetic acid (1 in 2) (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry (2.24): it exhibits maxima between 215 nm and 219 nm, and between 275 nm and 279 nm.
- Purity Related substances—Dissolve 1.0 mg in 1 mL of methanol, and perform the test with 1 $\mu$L of this solution as directed in the Identification (5) under Kakkonto Extract: no spot other than the principal spot ($R_f$ value is about 0.4) appears.
- Lisinopril See lisinopril hydrate.
- Lisinopril for assay See lisinopril hydrate for assay.
- Lisinopril hydrate $\text{C}_{21}\text{H}_{31}\text{N}_3\text{O}_5\cdot\text{H}_2\text{O}$ [Same as the namesake monograph]
- Lisinopril hydrate for assay $\text{C}_{21}\text{H}_{31}\text{N}_3\text{O}_5\cdot\text{H}_2\text{O}$ [Same as the monograph Lisinopril Hydrate. It contains not less than 99.5% of lisinopril ($\text{C}_{21}\text{H}_{31}\text{N}_3\text{O}_5$: 405.49), calculated on the anhydrous basis.]
- Lithium acetate dihydrate $\text{CH}_3\text{COOLi}\cdot\text{H}_2\text{O}$ Colorless crystals.
  Dilute acetic acid insoluble substances—To 40.0 g of lithium acetate dihydrate add 45 mL of water, heat in a water bath to dissolve, cool, then dissolve in dilute acetic acid, and filter by suction. Wash the filter with water, dry the filter at
105 ± 2°C for 1 hour, and weigh the mass of the residue after cooling: not more than 0.0025%.  

**Content:** not less than 97.0%. **Assay—**Weigh accurately 0.3 g of lithium acetate dihydrate, add exactly 50 mL of acetic acid (100) and exactly 5 mL of acetic anhydride, dissolve by heating in a water bath, and titrate with 0.1 mol/L perchloric acid VS after cooling (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 10.20 mg of CH₃COOLi.2H₂O

**Lithium bromide** LiBr White crystals or crystalline powder. It is hygroscopic.

**Purity** (1) Chloride <1.0%: not more than 0.1%.  
(2) Sulfate <1.14%: not more than 0.01%.

**Lithium chloride** LiCl White crystals or masses.  

**Identification—**Perform the test as directed under Flame Coloration Test (1) <1.0%: a persistent red color appears.

**Lithium perchlorate** LiClO₄ White, crystals or crystalline powder.

**Content**: not less than 98%. **Assay—**Accurately weigh about 0.2 g of lithium perchlorate, dissolve in 30 mL of water. Transfer the solution to a chromatographic column, prepared by pouring about 25 mL of strongly acidic ion-exchange resin (H type) for column chromatography into a chromatographic tube about 11 mm in inside diameter and about 300 mm in height (after adding 200 mL of 1 mol/L hydrochloric acid TS and flowing at a flow rate of 3 – 4 mL per minute, wash the chromatographic column with water until the color of the rinse water changes to yellowish red when adding methyl orange TS to the eluate), and flow at a flow rate of 3 – 4 mL per minute. Then, wash the column with about 30 mL of water at a flow rate of 3 – 4 mL per minute 5 times. Combine the rinse water and the eluate, and titrate with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of bromothymol blue TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 10.64 mg of LiClO₄

**Lithium sulfate** See lithium sulfate monohydrate.

**Lithium sulfate monohydrate** Li₂SO₄ . H₂O [K 8994, Special class]

**Lithocholic acid for thin-layer chromatography** C₂₄H₄₀O₃ White crystals or crystalline powder. Soluble in acetic acid (100) and exactly 5 mL of acetic anhydride, dissolve by heating in a water bath, and titrate with 0.1 mol/L perchloric acid VS after cooling (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 10.20 mg of CH₃COOLi.2H₂O

Prepare before use. The constituents except dextrose and sodium hydrogen carbonate can be made up in concentrated stock solutions, stored in a dark place, and diluted before use.

**Loganin for assay** Loganin for thin-layer chromatography meeting the following additional specifications.

**Absorbance** <2.24> E<sub>1</sub>₉₅₀ (235 nm): 275 – 303 (dried in a desiccator (silica gel) for 24 hours, 5 mg, methanol, 500 mL).

**Purity** Related substances—Dissolve 2 mg of loganin for assay in 5 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of this solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the total area of the peaks other than the peak of loganin is not larger than the peak area of loganin from the standard solution.

**Operating conditions**

Detector, column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay (1) under Goshajinkigan Extract.

Time span of measurement: About 3 times as long as the retention time of loganin.

**System suitability**

Test for required detectability: Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 20 mL. Confirm that the peak area of loganin obtained from 10 μL of this solution is equivalent to 3.5 to 6.5 μL of that of loganin from 10 μL of the standard solution.

**System performance and system repeatability:** Proceed as directed in the system suitability in the Assay (1) under Goshajinkigan Extract.

**Loganin for component determination** See loganin for assay.

**Loganin for thin-layer chromatography** C<sub>17</sub>H₂₆O₁₀ White, crystals or crystalline powder. Soluble in methanol and very slightly soluble in ethanol (99.5). Melting point: 221 – 227°C.

**Purity** Related substances—Dissolve 1.0 mg of loganin for thin-layer chromatography in 2 mL of methanol.
Perform the test with 10 μL of this solution as directed in the Identification under Cornus Fruit: any spot other than the principal spot at the RF value of about 0.4 does not appear.

**Lovastatin**

C_{27}H_{46}O_{4} White crystals or crystalline powder. Soluble in acetonitrile and in methanol, sparingly soluble in ethanol (99.5), and practically insoluble in water.

**Optical rotation** $\angle 2.493: \alpha [\beta ]_{D}^{20} +325 \pm 340^\circ$ (50 mg calculated on the dried basis, acetonitrile, 10 mL, 100 mm).

**Loss on drying** $\angle 2.475$: Not more than 1.0% (1 g, under reduced pressure not exceeding 0.67 kPa, 60°C, 3 hours).

**Low-molecular weight heparin for calculation of molecular mass.**

It is a low-molecular weight heparin with a disaccharide unit prepared, and display the molecular mass distribution between 600 and more than 10,000. When the average of molecular mass of Low-molecular weight heparin international standard is determined with reference to this, the difference compared as a reference with the Low-molecular weight heparin international standard is not less than 5%.

**Luteolin for thin-layer chromatography** C_{16}H_{18}O_{6}

Light yellow to yellow-brown crystalline powder. Slightly soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: about 310°C (with decomposition).

**Purity** Related substances—Dissolve 1.0 mg of luteolin for thin-layer chromatography in 1 mL of methanol. Proceed the test with 10 μL of this solution as directed in the Identification under Chrysanthemum Flower: any spot other than the principal spot of RF about 0.7 does not appear.

**Lysate reagent** A lyophilized product obtained from amebocyte lysate of horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). Amebocyte lysate preparations which do not react to β-glucans are available: they are prepared by removing the G factor reacting to β-glucans from amebocyte lysate or by inhibiting the G factor reacting system of amebocyte lysate.

**Lysate TS** Dissolve a lysate reagent in water for bacterial endotoxins test, or in a suitable buffer, by gentle stirring.

**Lysil endopeptidase** White powder or masses. An exotxin produced by *Achromobacter*. Molecular weight: 27,500.

**1-Lysine hydrochloride** C_{6}H_{12}N_{2}O_{2}.HCl [Same as the namesake monograph]

**Macrogol 600** HOCH_{2}(CH_{2}OCH_{2})_{n}CH_{2}OH, n = 11 – 13 Clear, colorless, viscous liquid or a white, petrolatum-like solid, having a faint, characteristic odor. Very soluble in water, in ethanol (95), in acetone and in macrogol 400, soluble in diethyl ether, and practically insoluble in petroleum benzine. Congealing point: 18 – 23°C

**Average molecular weight:** When perform the test as directed in the Average molecular weight test under Macrogol 400, it is between 570 and 630.

**4-(N-Maleimidylmethyl)-cyclohexane-1-carboxylate-N-hydroxysuccinimide ester** C_{19}H_{18}O_{5} Colorless crystals. Being decomposed by acid and alkaline treatment.

**Magnesia TS** Dissolve 5.5 g of magnesium chloride hexahydrate and 7 g of ammonium chloride in 65 mL of water, add 35 mL of ammonia TS, allow the mixture to stand for a few days in tightly stoppered bottles, and filter. If the solution is not clear, filter before use.

**Magnesium Mg** [K 8875, Special class]

**Magnesium chloride** See magnesium chloride hexahydrate.

**Magnesium chloride hexahydrate** MgCl_{2}.6H_{2}O [K 8159, Special class]

**Magnesium nitrate** See magnesium nitrate hexahydrate.

**Magnesium nitrate hexahydrate** Mg(NO_{3})_{2}.6H_{2}O [K 8567, Special class]

**Magnesium oxide** MgO [K 8432, Special class]

**Magnesium powder** Mg [K 8876, Special class]

**Magnesium sulfate** See magnesium sulfate heptahydrate.

**Magnesium sulfate heptahydrate** MgSO_{4}.7H_{2}O [K 8995, Special class]

**Magnesium sulfate TS** Dissolve 12 g of magnesium sulfate hexahydrate in water to make 100 mL (0.5 mol/L).

**Magnolol for assay** Use magnolol for thin-layer chromatography meeting the following additional specifications. Absorbance $\angle 2.47$ $E_{1}%^{10}$ (290 nm): 270 – 293 (10 mg, methanol, 500 mL). Use the sample dried in a desiccator (silica gel) for not less than 1 hour for the sample.

**Purity** Related substances—Dissolve 5.0 mg of magnolol for assay in 10 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL of each of the sample solution and standard solution as directed under Liquid Chromatography $\angle 2.07$ according to the following conditions, and determine the area of each peak from these solutions by the automatic integration method: the total area of peaks other than the peak of magnolol from the sample solution is not larger than the peak area of magnolol from the standard solution. Operating conditions:

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay under Magnolia Bark.

**Time span of measurement:** About 3 times as long as the retention time of magnolol.

**System suitability**

System performance, and system repeatability: Proceed as directed in the system suitability in the Assay under Magnolia Bark.

Test for required detectability: To exactly 1 mL of the standard solution add the mobile phase to make exactly 20 mL. Confirm that the peak area of magnolol obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.

**Magnolol for component determination** See magnolol for assay.

**Magnolol for thin-layer chromatography** C_{18}H_{22}O_{2} Odorless, white crystals or crystalline powder. Freely soluble in methanol and in ethanol (99.5), and practically insoluble.
in water. Melting point: about 102°C.

**Identification**—Determine the absorption spectrum of a solution of mannitol for thin-layer chromatography in methanol (1 in 50,000) as directed under Ultraviolet-visible Spectrophotometry <2.24> it exhibits a maximum between 287 nm and 291 nm.

**Purity** Related substances—Dissolve 1.0 mg of mannitol for thin-layer chromatography in 1 mL of methanol, and use this solution as the sample solution. Perform the test with the sample solution as directed under Thin-layer Chromatography <2.07>. Spot 10 μL of the sample solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography, develop the plate with a mixture of hexane, acetone and acetic acid (100) (20:15:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): any spot other than the principal spot of around Rt value of 0.5 does not appear.

**Malachite green** See malachite green oxalate.

**Malachite green oxalate** C₂₂H₁₄N₂O₁₂ [K 8878, Malachite green (oxalate), Special class]

**Maleic acid** C₇H₆O₄ A white crystalline powder.

**Identification**—Determine the infrared absorption spectrum of maleic acid as directed in the potassium bromide disk method as directed under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 1706 cm⁻¹, 1876 cm⁻¹, 1587 cm⁻¹, 1567 cm⁻¹, 1436 cm⁻¹, 1263 cm⁻¹, 876 cm⁻¹ and 786 cm⁻¹.

**4-(Maleimidomethyl)cyclohexylcarbolic acid-N-hydroxy-succinimide ester** C₁₆H₁₉N₃O₃ White powder. Practically insoluble in water and in ethanol (95).

**Maltose** See maltose monohydrate.

**Maltose monohydrate** C₁₂H₂₂O₁₁ ⋅ H₂O [Same as the namesake monograph].

**Maltotriose** C₁₈H₃₂O₁₆ A white powder.

**Identification**—Determine the infrared absorption spectrum of maltotriose as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3420 cm⁻¹, 1,153 cm⁻¹ and 1024 cm⁻¹.

**Manganese dioxide** MnO₂ Black to black-brown, masses or powder.

**Identification**—To 0.5 g add 20 mL of water and 3 mL of hydrogen peroxide (30). Alkalinate the solution with ammonia solution (28) while cooling, and add 25 mL of hydrogen sulfide TS: pale red precipitates appear.

**Manganese (II) nitrate hexahydrate** Mn(NO₃)₂ ⋅ 6H₂O [K 8568, Special class]

**d-Mannitol** C₆H₁₂O₆ [Same as the monograph d-Mannitol]

**d-Mannosamine hydrochloride** C₆H₁₂N₂O₄ ⋅ HCl White powder. Melting point: about 168°C (with decomposition). Optical rotation <2.49> [α]D²⁴: +4.2 — 3.2° (0.4 g, water, 20 mL, 100 mm).

**d-Mannose** C₆H₁₀O₅ White crystal or crystalline powder. It is very soluble in water. Melting point: about 132°C (with decomposition).
graph]

**Mentha herb** [Same as the namesake monograph]

**Menthol** C_{10}H_{20}O [Same as the monograph dl-Menthol or l-Menthol]

**l-Menthol for assay** [Same as the monograph l-Menthol. It contains not less than 99.0% of C_{10}H_{20}O and meets the following additional specifications.]

- **Optical rotation** \( < 2.0^\circ \) \( [\alpha]_D^20 \): \(-48.0^\circ \) to \(-51.0^\circ \) (2.5 g, ethanol (95), 25 mL, 100 mm).

**Purity** Related substances—Dissolve 0.10 g of l-menthol for assay in 10 mL of dichloromethane, and use this solution as the sample solution. Pipet 1 mL of this solution, add dichloromethane to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 5 \( \mu \)L each of the sample solution and standard solution (1) as directed under Gas Chromatography \( < 2.02 > \) according to the following conditions, measure each peak area of these solutions by the automatic integration method: the total peak area of l-menthol from the sample solution is not larger than the peak area of l-menthol from the standard solution (1).

**Operat conditions**

Proceed the operating conditions in the Assay under Mentha Oil except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add dichloromethane to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of l-menthol obtained from 5 \( \mu \)L of the standard solution (2) can be measured, and the peak height of l-menthol from 5 \( \mu \)L of the standard solution (1) is about 20% of the full scale.

**Time span of measurement:** About twice as long as the retention time of l-menthol beginning after the solvent peak.

**Mepivacaine hydrochloride for assay** C_{15}H_{22}N_{2}O.HCl [Same as the monograph Mepivacaine Hydrochloride. When dried, it contains not less than 99.0% of C_{15}H_{22}N_{2}O.HCl].

- **Detection sensitivity** so that the peak area of 2-mercaptoethanol is 3 – 4 times.

**Time span of measurement:** About 7 times as long as the retention time of 2-mercaptoethanol.

**Mercaptopurine** See mercaptopurine hydrate.

**Mercaptopurine hydrate** C_{10}H_{12}N_{4}S.H_{2}O [Same as the namesake monograph]

**Mercuric acetate** See mercury (II) acetate.

**Mercuric acetate TS for nonaqueous titration** See mercury (II) acetate TS for nonaqueous titration.

**Mercuric chloride** See mercury (II) chloride.

**Mercury Hg** [K 8572, Special class]

**Mercury (II) acetate** Hg(CH_{3}COO)_{2} White crystals or crystalline powder.

Identification—\( (1) \) Dissolve 1 g of mercury (II) chloride in 1 mL of dilute nitric acid (1 in 7), add 20 mL of water, and use this as the sample solution. To 10 mL of the sample solution add 0.8 mL of iron (III) chloride TS: a red-brown color is developed.

\( (2) \) To 10 mL of the sample solution obtained in \( (1) \) add 2 mL of potassium iodate TS: a red precipitate is produced. Preserve in a light-resistant tight container.

**Mercury (II) acetate TS for nonaqueous titration** Dissolve 5 g of mercury (II) acetate in acetic acid (100 mL) for nonaqueous titration to make 100 mL.

**Mercury (II) chloride HgCl_{2}** [K 8139, Special class]

**Mercury (II) chloride TS** Dissolve 5.4 g of mercury (II) chloride in water to make 100 mL.

**Mesaconitine for purity** C_{3}H_{7}NO_{11} White, crystals or crystalline powder. Slightly soluble in acetonitrile and in ethanol (99.5), very slightly soluble in diethyl ether, and practically insoluble in water. Melting point: about 190°C (with decomposition).

Identification—Determine the infrared absorption spectrum of mesaconitine for purity as directed in the potassium bromide disk method under Infrared Spectrophotometry \( < 2.25 > \): it exhibits absorption at the wave numbers of about 3510 cm\(^{-1}\), 1713 cm\(^{-1}\), 1277 cm\(^{-1}\), 1116 cm\(^{-1}\), 1098 cm\(^{-1}\) and 717 cm\(^{-1}\).

Absorbance \( < 2.25 \times E_{1%}^{1 cm} (230 nm): 211 – 247 \) [5 mg dried for not less than 12 hours in a desiccator (reduced pressure not exceeding 0.67 kPa, phosphorus (V) oxide, 40°C), ethanol (99.5), 200 mL].

Purity Related substances—\( (1) \) Dissolve 5.0 mg of mesaconitine for purity in 2 mL of acetonitrile, and use as the sample solution. Pipet 1 mL of the sample solution, add acetonitrile to make exactly 50 mL, and use as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography \( < 2.03 > \). Spot 20 \( \mu \)L each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography, and proceed the test...
as directed in the Identification under Processed Aconite Root: the spot other than the principal spot is not more intense than the spot with the standard solution.

(2) Dissolve 5.0 mg of mesaconitine for purity in 5 mL of acetonitrile, and use as the sample solution. Pipet 1 mL of the sample solution, add acetonitrile to make exactly 50 mL, and use as the standard solution. Perform the test with exactly 10 μL of each of the sample solution and standard solution as directed under Liquid Chromatography (2.01) according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than the peaks of mesaconitine and the solvent is not larger than the peak area of mesaconitine with the standard solution.

Operating conditions
Detector, column, and column temperature: Proceed as directed in the operating conditions in the Purity under Processed Aconite Root.

Mobile phase: A mixture of phosphate buffer solution for processed aconite root and tetrahydrofuran (9:1).

Flow rate: Adjust the flow rate so that the retention time of mesaconitine is about 19 minutes.

Time span of measurement: About 3 times as long as the retention time of mesaconitine.

System suitability
Test for required detectability: Pipet 1 mL of the standard solution, and add acetonitrile to make exactly 20 mL. Confirm that the peak area of mesaconitine obtained from 10 μL of this solution is equivalent to 3.5 to 6.5

System performance: Dissolve 1 mg each of aconitine for purity, hypaconitine for purity and mesaconitine for purity, and 8 mg of jesaconitine for purity in 200 mL of acetonitrile. When the procedure is run with 10 μL of this solution under the above operating conditions, mesaconitine, hypaconitine, aconitine and jesaconitine are eluted in this order, and each resolution between these peaks is not less than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of mesaconitine is not more than 1.5%

Water (2.48): not more than 1.0% [5 mg dried for not less than 12 hours in a desiccator (reduced pressure not exceeding 0.67 kPa, phosphorus (V) oxide) for 4 hours. It is white, odorless crystals. Recrystallize in the same manner, and dry the crystals in a desiccator in vacuum, phosphorus (V) oxide) for 4 hours. It is white, odorless crystals. Absorbance <2.24> E<sub>1%1 cm</sub> (242 nm): 321 – 328 (1 mg, methanol, 100 mL).

Specific gravity <2.56> d<sub>4</sub>: 0.850 – 0.860

Metacresol purple CH<sub>3</sub>CH<sub>2</sub>H<sub>2</sub>OH [K 8889, Special class]

Metacresol purple TS Dissolve 0.10 g of metacresol purple in 13 mL of 0.01 mol/L sodium hydroxide TS, and add water to make 100 mL.

Metacycline hydrochloride C<sub>27</sub>H<sub>42</sub>O<sub>3</sub>N<sub>2</sub>HCl Yellow to dark yellow, crystals or crystalline powder.

Purity Related substances—Dissolve 20 mg of metacycline hydrochloride in 25 mL of 0.01 mol/L hydrochloric acid TS, and use this solution as the sample solution. Proceed the test with 20 μL of the sample solution as directed in the Purity (2) under Doxycycline Hydrochloride Hydrate, determine each peak area by the automatic integration method, and calculate the amounts of them by the area percentage method: the total area of peaks other than metacycline is not more than 10%.

Metallic sodium See sodium.

Metanil yellow C<sub>18</sub>H<sub>14</sub>N<sub>3</sub>NaO<sub>3</sub>S Yellow-brown powder. Sparingly soluble in water, and very slightly soluble in ethanol (95%) and in N,N-dimethylformamide.

Metanil yellow TS Dissolve 0.1 g of metanil yellow in 200 mL of N,N-dimethylformamide.

Metaphosphoric acid HPO<sub>3</sub> A colorless, deliquescent stick or masses.

Identification—(1) Dissolve 1 g of metaphosphoric acid in 50 mL of water, and use this as the sample solution. To 10 mL of the sample solution add 0.2 mL of ammonia TS and 1 mL of silver nitrate TS: a yellowish white precipitate is produced.

(2) To 10 mL of the sample solution obtained in (1) add 10 mL of albumin TS: a white precipitate is produced.

Metaphosphoric acid-acetic acid TS Dissolve 15 g of metaphosphoric acid and 40 mL of acetic acid (100) in water to make 500 mL. Preserve in a cold place, and use within 2 days.

Metenolone enanthate C<sub>18</sub>H<sub>14</sub>N<sub>3</sub>NaO<sub>3</sub>S [Same as the name-sake monograph]

Metenolone enanthate for assay C<sub>18</sub>H<sub>14</sub>N<sub>3</sub>NaO<sub>3</sub>S To 1 g of metenolone enanthate add 30 mL of water, and add slowly 70 mL of methanol with warming to dissolve. Filter while hot, and allow the filtrate to stand on a water bath for 30 minutes. Allow to stand overnight in a cold place, collect the crystals thus formed, and wash with a small amount of diluted methanol (1 in 3). Recrystallize in the same manner, and dry the crystals in a desiccator (in vacuum, phosphorus (V) oxide) for 4 hours. It is white, odorless crystals.

Absorbance <2.24> E<sub>1%1 cm</sub> (242 nm): 321 – 328 (1 mg, methanol, 100 mL).

Optical rotation <2.49> [α]<sub>D</sub>: +40 – +42° (0.2 g, chloroform, 10 mL, 100 mm).

Melting point <2.60>: 69 – 72°C

Purity Related substances—Dissolve 50 mg of metenolone enanthate for assay in chloroform to make exactly 10 mL, and use this solution as the sample solution. Proceed with 10 μL of this solution as directed in the Purity (3) under Metenolone Enanthate: any spot other than the principal spot does not appear.

Metformin hydrochloride for assay C<sub>6</sub>H<sub>11</sub>N<sub>2</sub>Cl [Same as the monograph Metformin Hydrochloride. When dried, it contains not less than 99.0% of metformin hydrochloride (C<sub>6</sub>H<sub>11</sub>N<sub>2</sub>Cl)].

Methanesulfonic acid CH<sub>3</sub>SO<sub>3</sub>H Clear, colorless liquid or colorless or white, crystalline mass, having a characteristic odor. Miscible with water, with ethanol (95) and with diethyl ether.

Conspicuousness <2.42>: 15 – 20°C
Specific gravity <2.56> d<sub>4</sub>: 1.483 – 1.488
Content: not less than 99.0%. Assay—Weigh accurately about 2 g of methanesulfonic acid, dissolve in 40 mL of water, and titrate <2.50> with 1 mol/L sodium hydroxide VS
Methanesulfonic acid TS To 35 mL of methanesulfonic acid add 20 mL of acetic acid (100) and water to make 500 mL.

0.1 mol/L Methanesulfonic acid TS To 4.8 g of methanesulfonic acid add water to make 500 mL.

Methanol CH₃OH [K 8891, Special class]

Methanol, anhydrous CH₃O To 1000 mL of methanol add 5 g of magnesium powder. If necessary, add 0.1 mL of mercury (II) chloride TS to start the reaction. After the evolving of a gas is stopped, distillate the solution, and preserve the distillate protecting from moisture. Water content per mL is not more than 0.3 mg.

Methanol-free ethanol See ethanol (95), methanol-free.

Methanol-free ethanol (95) See ethanol (95), methanol-free.

Methanol, purified Distil methanol before use.

Methionin See L-methionine.

1-Methionine C₇H₁₅NO₂S [Same as the namesake monograph]

Methotrexate C₂₀H₂₂N₈O₅ [Same as the namesake monograph]

4-Methoxybenzaldehyde C₈H₉O₂ Clear, colorless to pal yellow liquid. Miscible with methanol and with ethanol (99.5), and slightly soluble in water. Congealing point: 3 – 8°C.

Identification—Determine the infrared absorption spectrum of 4-methoxybenzaldehyde as directed in the ATR method under Infrared Spectrophotometry: it exhibits absorption at the wave numbers of about 3421 cm⁻¹, 2923 cm⁻¹, 1610 cm⁻¹, 1460 cm⁻¹, 1220 cm⁻¹, and 1031 cm⁻¹.

Purity Related substances—Perform the test with 0.2 μL of 4-methoxybenzaldehyde as directed under Gas Chromatography: according to the following conditions. Determine each peak by the automatic integration method: the total area of the peaks other than the peak of 4-methoxy-4-methylphenol is not more than 3.0%.

Operating conditions
Detector: A hydrogen flame-ionization detector.
Column: A fused silica column 0.25 mm in inside diameter and 60 m in length, coated inside with polydimethylsiloxane for gas chromatography in 0.25 to 0.5 μm in thickness.

Column temperature: Inject at a constant temperature of about 100°C, raise the temperature to 130°C at a rate of 5°C per minute, raise to 140°C at a rate of 2°C per minute, raise to 200°C at a rate of 15°C per minute, and maintain at 200°C for 2 minutes.

Injection port temperature: 200°C.
Detector temperature: 250°C.
Carrier gas: Helium.
Flow rate: Adjust the flow rate so that the retention time of 2-methoxy-4-methylphenol is about 10 minutes.  
Split ratio: 1:50.

System suitability  
System performance: Dissolve 60 mg of 2-methoxy-4-methylphenol in methanol to make 100 mL, and use this solution as the solution for system suitability test. Proceed with 1 μL of the solution for system suitability test under the above operating conditions, the symmetry factor of the peak of 2-methoxy-4-methylphenol is not more than 1.5.

System repeatability: When the test is repeated 6 times with 1 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of 2-methoxy-4-methylphenol is not more than 2.0%.

1-Methoxy-2-propanol C7H12O2  A colorless, clear liquid.

Clarity of solution—To 5 mL of 1-methoxy-2-propanol add 20 mL of water, and mix: the solution is clear.
Refractive index <2.45> nD20: 1.402 – 1.405  
Specific gravity <2.56> d20: 0.920 – 0.925  
Water <2.49> not more than 0.5% (5 g).

Content: not less than 98.0%. Assay—Proceed as directed under Gas Chromatography <2.02> using the area percentage method according to the following conditions:
Operating conditions  
Detector: Thermal conductivity detector.  
Column: A glass column about 3 mm in inside diameter and about 2 m in length, packed with siliceous earth for gas chromatography (150 to 180 μm) coated with polyethylene glycol 20 M for gas chromatography in 20%.

Column temperature: A constant temperature of about 90°C.
Carrier gas: Helium.

Flow rate: A constant flow rate of 20 mL per minute.

Methyl acetate CH3COOCH3  [K 8382, Special class]

p-Methyl aminophenol sulfate See 4-methyl aminophenol sulfate.

4-Methyl aminophenol sulfate (HOCH2NHCH2)2H2SO4  White to pale yellow or very pale grayish white, crystals or crystalline powder. Melting point: about 260°C (with decomposition).

p-Methyl aminophenol sulfate TS  See 4-methyl aminophenol sulfate TS.

4-Methyl aminophenol sulfate TS  Dissolve 0.35 g of 4-methyl aminophenol sulfate and 20 g of sodium hydrogen sulfite in water to make 100 mL. Prepare before use.

2-Methylnaphthopyridine C9H7N  A pale yellow liquid.

Specific gravity <2.56> d<sub>20</sub>: 1.050 – 1.065  
Boiling point <2.57>: 200 – 202°C  
Water <2.49>: less than 0.1%.

2-Methylnaphthopyridine for Karl Fischer method  See Water Determination <2.487>.

Methyl behenate C32H52O2  White, odorless and tasteless, scaly crystals or powder. Dissolves in acetone, in diethyl ether and in chloroform.
Melting point <2.60>: 54°C  
Saponification value <1.13>: 155.5 – 158.5  
Methyl benzoate C9H8O2  Clear, colorless liquid.

Refractive index <2.45> nD20: 1.515 – 1.520  
Specific gravity <2.56> d20: 1.087 – 1.095

Purity—Dissolve 0.1 mL of methyl benzoate in the mobile phase in Assay under Thiamine Hydrochloride to make 50 mL. Perform the test as directed under Liquid Chromatography <2.01> with 10 μL of this solution according to the Assay under Thiamine Hydrochloride. Measure each peak area by the automatic integration method in a range about twice the retention time of methyl benzoate, and calculate the amount of methyl benzoate by the area percentage method: it shows the purity of not less than 99.0%.

Methyl benzoate for estriol test C9H8O2  Clear, colorless liquid, having a characteristic odor.

Refractive index <2.45> nD20: 1.515 – 1.520  
Specific gravity <2.56> d20: 1.087 – 1.095  
Acid value <1.13>: not more than 0.5.

D(+)-α-Methylbenzylamine C7H9(CH2CH3)NH2  Colorless or pale yellow clear liquid, having an amine like odor. Miscible with ethanol (95) and with acetone, and slightly soluble in water.

Refractive index <2.45> nD20: 1.524–1.529  
Optical rotation <2.49> [α]D<sub>20</sub>: +37 – +41° (50 mm).

Content: not less than 98.0%. Assay—Perform the test with exact 0.6 μL of D(+)-α-methylbenzylamine as directed under Gas Chromatography <2.02> according to the following conditions. Measure each peak area by the automatic integration method, and calculate the amount of D(+)-α-methylbenzylamine.

Operating conditions  
Detector: Hydrogen flame-ionization detector.  
Column: A glass column about 3 mm in inside diameter and about 2 m in length, packed with siliceous earth for gas chromatography (150 to 250 μm in particle diameter) coated with polyethylene glycol 20 M for gas chromatography and potassium hydroxide at the ratio of 10% and 5%, respectively.

Column temperature: A constant temperature of about 140°C.
Carrier gas: Helium.

Flow rate: Adjust the flow rate so that the retention time of D(+)-α-methylbenzylamine is about 5 minutes.

Selection of column: To 5 mL of D(+)-α-methylbenzylamine add 1 mL of pyridine. Proceed with 0.6 μL of this solution under the above operating conditions, and calculate the resolution. Use a column giving elution of pyridine and p(+)α-methylbenzylamine in this order with the resolution between these peaks being not less than 3.

Time span of measurement: About 3 times as long as the retention time of D(+)-α-methylbenzylamine beginning after the solvent peak.

3-Methyl-1-butanol C8H16O  [K 8051, Special class]

3-Methylbutyl acetate CH3COOCH2CH2CH(CH3)2  A clear and colorless liquid. Boiling point: about 140°C.

Specific gravity <2.56> d20: 0.868 – 0.879  
Preserve in a light-resistant tight container.

Methyl cellosolve  See 2-methoxyethanol.

Methyl docosanate C32H64O2  White, tabular crystals or crystalline powder.

Melting point <2.60>: 51.0 – 56.0°C
Methyldopa  See methyldopa hydrate.
Methyldopa for assay  See methyldopa hydrate for assay.
Methyldopa hydrate  \( C_{10}H_{13}NO_4 \cdot \frac{1}{2}H_2O \) [Same as the namesake monograph]
Methyldopa hydrate for assay  \( C_{10}H_{13}NO_4 \cdot \frac{1}{2}H_2O \) [Same as the monograph Methyldopa Hydrate. It contains not less than 99.0% of methyldopa \( (C_{10}H_{13}NO_4) \), calculated on the anhydrous basis.]
\( N,N' \)-Methylenebisacrylamide  \( CH_2(NHCOCHCH_2)_2 \) White crystalline powder. Content: not less than 97.0%.
Methylene blue  See methylene blue trihydrate.
Methylene blue-sulfuric acid-monobasic sodium phosphate TS  See methylene blue-sulfuric acid-sodium dihydrogenphosphate TS.
Methylene blue-sulfuric acid-sodium dihydrogenphosphate TS  To 30 mL of a solution of methylene blue (1 in 1000) add 500 mL of water, 6.8 mL of sulfuric acid and 50 g of sodium dihydrogenphosphate dihydrate, dissolve, and add water to make 1000 mL.
Methylene blue trihydrate  \( C_{16}H_{16}ClN_3S \cdot 3H_2O \) [K 8997, Special class]
Methylene blue TS  Dissolve 0.1 g of methylene blue trihydrate in water to make 100 mL. Filter if necessary.
\( dl \)-Methylenebisacrylamide hydrochloride  \( C_{11}H_{17}NO \cdot HCl \) [Same as the namesake monograph]
\( dl \)-Methylenebisacrylamide hydrochloride for assay  [Same as the monograph \( dl \)-Methylenebisacrylamide Hydrochloride]
Methylergometrine maleate for assay  \( C_{29}H_{32}N_6O_5 \cdot C_5H_8O_4 \) [Same as the monograph Methylergometrine Maleate. When dried, it contains not less than 99.0% of methylergometrine maleate \( (C_{29}H_{32}N_6O_5 \cdot C_5H_8O_4) \).]
Methyl ethyl ketone  See 2-butanone.
Methyl iodide  See iodomethane.
Methyl iodide for assay  See iodomethane for assay.
Methyl isobutyl ketone  See 4-methyl-2-pentanone.
3-O-Methylmethyldopa for thin-layer chromatography  \( C_{13}H_{15}NO_4 \)

Purity  Related substances—Dissolve 5 mg of 3-O-methylmethyldopa for thin-layer chromatography in methanol to make exactly 100 mL. Perform the test with 20 \( \mu L \) of this solution as directed in the Purity (5) under Methyldopa: any spot other than the principal spot at the \( R_f \) value of about 0.7 does not appear.

2-Methyl-5-nitroimidazole for thin-layer chromatography  \( C_{6}H_{12}N_2O_2 \) White crystalline powder. Slightly soluble in water and in acetone. Melting point: about 253°C (with decomposition).

Purity  Related substances—Dissolve 40 mg of 2-methyl-5-nitroimidazole for thin-layer chromatography in 8 mL of acetone, and use as the sample solution. Pipet 2.5 mL of the sample solution, add acetone to make exactly 100 mL, and use as the standard solution. Perform the test as directed in the Purity (3) under Metronidazole: the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

Methyl orange  \( C_{16}H_{18}ClN_3S \cdot 3H_2O \) [K 8993, Special class]
Methyl orange-boric acid TS  Add 0.5 g of methyl orange and 5.2 g of boric acid in 500 mL of water, and dissolve by warming on a water bath. After cooling, wash this solution with three 50-mL portions of chloroform.
Methyl orange TS  Dissolve 0.1 g of methyl orange in 100 mL of water, and filter if necessary.
Methyl orange-xylene cyanol FF TS  Dissolve 1 g of methyl orange and 1.4 g of xylene cyanol FF in 500 mL of dilute ethanol.
Methyl parahydroxybenzoate  \( \text{HOCH}_2\text{COOCH}_3 \) [Same as the namesake monograph]
4-Methylpentan-2-ol  \( \text{C}_6\text{H}_{14} \) A clear and colorless, volatile liquid.

Refractive index  \( <2.45> : \text{about} 1.411 \)
Specific gravity  \( <2.56> : \text{about} 0.802 \)
Boiling point  \( <2.57> : \text{about} 132°C \)

Methyl-2-pentanone  \( \text{CH}_3\text{COCH}_2\text{CH}(\text{CH}_3)_2 \) [K 8903, Special class]
3-Methyl-1-phenyl-5-pyrazolone  \( \text{C}_10\text{H}_{10}N_2 \) [K 9548, Special class]
Methyl prednisolone  \( \text{C}_{22}\text{H}_{36}O_3 \) [Same as the namesake monograph]
2-Methyl-1-propanol  \( \text{CH}_3\text{CH}_2\text{CH}_2\text{OH} \) [K 8811, Special class]

\( N \)-Methylpyrrolidine  \( \text{C}_4\text{H}_9\text{N} \) Colorless, clear liquid, having a characteristic order.

Identification—Determine the spectrum of \( N \)-methylpyrrolidine in a solution of deuterated chloroform for nuclear magnetic resonance spectroscopy (4 in 50) as directed under Nuclear Magnetic Resonance Spectroscopy \( <2.27> \) \( (\text{H}) \): it exhibits a big signal, at around \( \delta \) 2.3 ppm.

Content: not less than 95%.—Assay—Put 30 mL of water in a beaker, weigh accurately the beaker, add dropwise about 0.15 g of \( N \)-methylpyrrolidine, weigh accurately the beaker again, and titrate \( <2.50> \) with 0.05 mol/L sulfuric acid VS (potentiometric titration). Perform a blank determination in the same manner and make any necessary correction.

Each mL of 0.05 mol/L sulfuric acid VS = 8.515 mg of \( \text{C}_4\text{H}_9\text{N} \)

Methyl red  \( \text{C}_{12}\text{H}_{15}\text{N}_2 \) [K 8896, Special class]
Methyl red-methylene blue TS  Dissolve 0.1 g of methyl red and 0.1 g of methylene blue in ethanol (95) to make 100 mL, and filter if necessary. Preserve in light-resistant containers.
Methyl red TS  Dissolve 0.1 g of methyl red in 100 mL of ethanol (95), and filter if necessary.
Methyl red, dilute  Dissolve 25 mg of methyl red in 100 mL of ethanol (99.5), and filter if necessary. Prepare before use.

Methyl red TS for acidity or alkalinity test  To 0.1 g of
methyl red add 7.4 mL of 0.05 mol/L sodium hydroxide VS or 3.7 mL of 0.1 mol/L sodium hydroxide VS, triturate to dissolve in a mortar, and add freshly boiled and cooled water to make 200 mL. Preserve in light-resistant, glass-stoppered bottles.

**Methyrosaniline chloride** See crystal violet.

**Methyrosaniline chloride TS** See crystal violet TS.

**Methyl salicylate** C₇H₆O₃ [Same as the namesake monograph]

**Methylsilicone polymer** for gas chromatography Prepared for gas chromatography.

**Methyltestosterone** C₁₉H₂₉NO₃ [Same as the namesake monograph]

1-Methyl-1H-tetrazole-5-thiol C₆H₈N₅S White, crystals or crystalline powder.

**Identification** (1) Determine the ultraviolet-visible absorption spectrum of a solution of 1-methyl-1H-tetrazole-5-thiol (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry < 2.24: it exhibits a maximum between 222 nm and 226 nm.

(2) Determine the infrared absorption spectrum of 1-methyl-1H-tetrazole-5-thiol according to the potassium bromide disk method under Infrared Spectrophotometry < 2.25: it exhibits absorption at the wave numbers of about 3060 cm⁻¹, 2920 cm⁻¹, 2780 cm⁻¹, 1500 cm⁻¹, 1430 cm⁻¹ and 1410 cm⁻¹.

**Melting point** < 2.60: 125 – 129°C

**Purity** Related substances—Dissolve 0.1 g of 1-methyl-1H-tetrazole-5-thiol in exactly 100 mL of water. Perform the test with 1 μL of this solution as directed in the Purity (4) under Cefmetazole Sodium: any spot other than the principal spot at the Rf value of about 0.77 does not appear.

1-Methyl-1H-tetrazole-5-thiol for liquid chromatography C₆H₈N₅S White, crystals or crystalline powder. Very soluble in methanol, and freely soluble in water.

**Melting point** < 2.60: 123 – 127°C

**Loss on drying** < 2.47: not more than 1.0% (1 g, in vacuum, phosphorous(V) oxide, 2 hours).

**Content:** not less than 99.0%. Assay—Weigh accurately about 2 g of 1-methyl-1H-tetrazole-5-thiol, previously dried, dissolve in 80 mL of N,N-dimethylformamide, and titrate < 2.50 with 0.1 mol/L sodium methoxide VS (indicator: 3 drops of thymol blue-N,N-dimethylformamide TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium methoxide VS = 11.61 mg of C₆H₈N₅S

**Methylthymol blue** C₁₇H₁₉N₃O₁₁S [K 9552]

**Methylthymol blue-potassium nitrate indicator** Mix 0.1 g of methylthymol blue with 9.9 g of potassium nitrate, and triturate until the mixture becomes homogeneous.

**Sensitivity**—When 0.02 g of methylthymol blue-potassium nitrate indicator is dissolved in 100 mL of 0.02 mol/L sodium hydroxide VS, the solution is slightly blue in color. On adding 0.05 mL of 0.01 mol/L barium chloride VS to this solution, the solution shows a blue color, then on the subsequent addition of 0.1 mL of 0.01 mol/L disodium ethylenediaminetaacetate VS, it becomes colorless.

**Methyethylol blue-sodium chloride indicator** Mix 0.25 g of methylthymol blue and 10 g of sodium chloride, and grind to homogenize.

**Methyl yellow** C₁₄H₁₁N₃ [K 8494, Special class]

**Methyl yellow TS** Dissolve 0.1 g of methyl yellow in 200 mL of ethanol (95).

**Metoclopramide for assay** C₁₄H₂₁Cl₄N₂O₂ [Same as the monograph Metoclopramide. When dried, it contains not less than 99.0% of metoclopramide (C₁₄H₂₁Cl₄N₂O₂).]

**Metoprol tartrate for assay** (C₅H₇NO₄)₃C₂H₆O₆ [Same as the monograph Metoprol Tartrate. When dried, it contains not less than 99.5% of metoprol tartrate ((C₅H₇NO₄)₃C₂H₆O₆).]

**Metronidazole** C₁₅H₁₂N₃O [Same as the namesake monograph]

**Metronidazole for assay** C₁₅H₁₂N₃O [Same as the monograph Metronidazole. It meets the following additional requirement.]

**Related substances**—Weigh accurately about 25 mg of metronidazole for assay, dissolve in a mixture of water and methanol (4:1) to make exactly 100 mL, and use this solution as the sample solution. Pipet 2 mL of the sample solution, and add the mixture of water and methanol (4:1) to make exactly 30 mL. Pipet 2.5 mL of this solution, add the mixture of water and methanol (4:1) to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the standard solution and standard solution as directed under Liquid Chromatography < 2.01 according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than metronidazole is not more than the peak area of metronidazole with the standard solution.

**Operating conditions**
- **Detector**, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay under Metronidazole Tablets.
- **Time span of measurement:** About 4 times as long as the retention time of metronidazole.

**System suitability**
- **Test for required detectability:** Measure exactly 2 mL of the standard solution, add a mixture of water and methanol (4:1) to make exactly 20 mL. Confirm that the peak area of metronidazole obtained with 10 μL of this solution is equivalent to 7 to 13% of that with the standard solution.
- **System performance:** When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of metronidazole are not less than 3000 and not more than 1.5, respectively.

**System repeatability**: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of metronidazole is not more than 2.0%.

**Miconazole nitrate** C₁₈H₂₂Cl₂N₃O.HNO₃ [Same as the namesake monograph]

**Microplates** Polystyrene plates with an inside diameter of 7 (upper edge) to 6.4 (lower edge) mm, and 11.3 mm thickness. Have 96 flat-bottomed truncated cone-shaped wells.
Milk casein  See casein, milk.

Milk of lime  Place 10 g of calcium oxide in a mortar, and add gradually 40 mL of water under grinding.

Minocycline hydrochloride  C_{23}H_{27}N_{3}O_{7}.HCl  [Same as the namesake monograph]

Mixture of petroleum hexamethyl tetracosane branching hydrocarbons (L) for gas chromatography  Prepared for gas chromatography.

Molecular weight markers for teceleukin  Dissolve 0.4 mg of lysozyme, soy trypsin inhibitor, carbonic anhydrase, egg white albumin, bovine serum albumin, and phosphorylase b in 200 μL of diluted glycerin (1 in 2).

Molybdenum (III) oxide  MoO_{3}  A white to yellowish green powder.

Identification—Dissolve 0.5 g in 5 mL of ammonia solution (28), acidify 1 mL of this solution with a suitable amount of nitric acid, add 5 mL of sodium phosphate TS, and warm: yellow precipitates appear.

Molybdenum (III) oxide-citric acid TS  To 54 g of molybdenum (III) oxide and 11 g of sodium hydroxide add 200 mL of water, and dissolve by heating while stirring. Separately, dissolve 60 g of citric acid monohydrate in 250 mL of water, and add 140 g of hydrochloric acid. Mix these solutions, filter if necessary, add water to make 1000 mL, and add a solution of potassium bromate (1 in 100) until a yellow-green color appears.

Storage—Preserve in tightly stoppered containers, protected from light.

Molybdenum trioxide  See molybdenum (III) oxide.

Molybdenum trioxide-citric acid TS  See molybdenum (III) oxide-citric acid TS.

Morphine hydrochloride  See morphine hydrochloride hydrate.

Morphine hydrochloride for assay  See morphine hydrochloride hydrate for assay.

Morphine hydrochloride hydrate  C_{17}H_{19}NO_{3}.HCl.3H_{2}O  [Same as the namesake monograph]

Morphine hydrochloride hydrate for assay  C_{17}H_{19}NO_{3}.HCl.3H_{2}O  [Same as the monograph Morphine Hydrochloride Hydrate. It contains not less than 99.0% of morphine hydrochloride (C_{17}H_{19}NO_{3}.HCl), calculated on the anhydrous basis.]

3-(N-Morpholino)propanesulfonic acid  C_{7}H_{12}NO_{3}S

White crystalline powder, freely soluble in water, and practically insoluble in ethanol (99.5).

Melting point <2.60>: 275 – 280°C

0.02 mol/L  3-(N-Morpholino)propanesulfonic acid buffer solution, pH 7.0  Dissolve 4.2 g of 3-(N-morpholino)propanesulfonic acid in 900 mL of water, adjust the pH to 7.0 with dilute sodium hydroxide TS, and add water to make 1000 mL.

0.1 mol/L  3-(N-Morpholino)propanesulfonic acid buffer solution, pH 7.0  Dissolve 20.92 g of 3-(N-morpholino)propanesulfonic acid in 900 mL of water, adjust the pH to 7.0 with sodium hydroxide TS, and add water to make 1000 mL.

0.02 mol/L  3-(N-Morpholino)propanesulfonic acid buffer solution, pH 8.0  Dissolve 4.2 g of 3-(N-morpholino)propanesulfonic acid in 700 mL of water, adjust the pH to 8.0 with dilute sodium hydroxide TS, and add water to make 1000 mL.

Mosapride citrate for assay  See mosapride citrate hydrate for assay.

Mosapride citrate hydrate for assay  C_{21}H_{25}ClFN_{3}O_{3}.C_{6}H_{8}O_{7}.2H_{2}O  [Same as the monograph Mosapride Citrate Hydrate. It contains not less than 99.0% of mosapride citrate (C_{21}H_{25}ClFN_{3}O_{3}.C_{6}H_{8}O_{7}) calculated on the anhydrous basis.]
an autoclave for 15 minutes at 121°C to make the PBS(–) solution. Dissolve 0.3 g of 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyl-2H-tetrazolium bromide in this PBS(–) solution to make 100 mL. Sterilize by membrane filtration (pore size, 0.45 μm), and store in a cool place shielded from light.

Murexide C₉H₇N₂O₂ Red-purple powder. Practically insoluble in water, in ethanol (95) and in diethyl ether. 

Purity Clarity of solution—Dissolve 10 mg of murexide in 100 mL of water: the solution is clear. 

Residue on ignition <2.44%: not more than 0.1% (1 g).

Sensitivity—Dissolve 10 mg of murexide in 2 mL of ammonium-ammonium chloride buffer solution, pH 10.0, and add water to make 100 mL, and use this solution as the sample solution. Separately, add 2 mL of ammonium ammonium chloride buffer solution, pH 10.0, to 5 mL of diluted Standard Calcium Solution (1 in 10), add water to make 25 mL, and render the solution to pH 11.3 with sodium hydroxide VS: a green color develops. Add subsequently 0.2 mL of 0.1 mol/L sodium hydroxide VS: a bright yellow color develops.

Water <2.46%: 7.0–11.5% (0.5 g, volumetric titration, direct titration).

Content: not less than 95.0%, calculated on the anhydrous basis. Assay—Weigh accurately about 0.5 g of 2-naphthalenesulfonic acid hydrate, dissolve in 30 mL of water, and titrate <2.59% with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of bromothymol blue TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 20.82 mg of C₉H₇O₃S

1-Naphthol C₁₀H₇OH [K 8698, Special class] Preserve in light-resistant containers.

2-Naphthol C₁₀H₇OH [K 8699, Special class] Preserve in light-resistant containers.

Naringin dihydrate for thin-layer chromatography

Naringin for thin-layer chromatography

Neocarzinostatin-styrene-maleic acid alternating copolymer partial butyl ester condensate (2:3)

An amido binding condensate of neocarzinostatin and styrene-maleic acid alternating copolymer partial butyl ester in a rate of 2:3. Average molecular mass: about 28,400. A pale yellow powder.

Identification—Dissolve 4 mg of the substance to be examined in 0.05 mol/L phosphate buffer solution, pH 7.0 to make 10 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry. <2.24>: it exhibits a maximum between 266 nm and 270 nm, and shoulders between 257 nm and 262 nm, between 286 nm and 291 nm and between 318 nm and 348 nm.

Absorbance <2.24> \(E_{10}^{100}(268 \text{ nm})\): 13.0 – 17.5 [4 mg calculated on the anhydrous basis, 0.05 mol/L phosphate buffer solution, pH 7.0, 10 mL]

Purity—Proceed as directed in the Purity (3) under Zinostatin Stimalamer, with the exception of without using of (iii) Standard solution, and changing (iv) Sample solution, (v) Procedure and (vii) Determination as follows:

(iv) Sample solution Dissolve 3.0 mg of the substance to be examined in the buffer solution for sample to make 10 mL.

(v) Procedure Mount the gel in the electrophoresis apparatus. Add a mixture of 200 mL of Solution F and 2 mL of bromophenol blue solution (1 in 100,000) to the top reservoir (cathode) and 300 mL of Solution F to the lower reservoir (anode). Introduce carefully exactly 100 \(\mu\text{L}\) of the sample solution onto the surface of the gel, and allow electrophoresis at room temperature to take place with a current of 2 mA per tube as a bromophenol blue band is passing in the stacking gel and then increase the current to 4 mA per tube as the bromophenol blue band is passing in the resolving gel, and stop the current when the band reached at 5 cm from the upper end of the gel.

(vii) Determination Determine the peak area, \(A_T\), of neocarzinostatin-styrene-maleic acid alternating copolymer partial butyl ester condensate (2:3) and the total area, \(A\), of the peaks other than neocarzinostatin-styrene-maleic acid alternating copolymer partial butyl ester condensate (2:3), based on the absorbance at 600 nm of the gel determined by using a densitometer. Calculate the amount of neocarzinostatin-styrene-maleic acid alternating copolymer partial butyl ester condensate (2:3) by the following formula: not less than 90.0%.

Amount (%) of neocarzinostatin-styrene-maleic acid alternating copolymer partial butyl ester condensate (2:3) = \(\frac{[A_T/(A_T + A)] \times 100}{\ aspiration time of neocarzinostatin is about 21 minutes.

Time span of measurement: About 2 times as long as the retention time of neocarzinostatin.

System suitability

System performance: When the procedure is run with 0.25 mL of the sample solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of neocarzinostatin are not less than 2000 and not more than 2.5, respectively.

System repeatability: When the test is repeated 6 times with 0.25 mL of the sample solution under the above operating conditions, the relative standard deviation of the peak area of neocarzinostatin is not more than 2.0%.

Water <2.40> Not more than 10.0% (10 mg, coulometric titration).
**JP XVI**

**General Tests / 9.41 Reagents, Test Solutions**

**Water** [2.48] Not more than 12.0% (10 mg, coulometric titration).

**Neutral alumina containing 4% of water** Take 50 g of neutral alumina for column chromatography, previously dried at 105°C for 2 hours, in a tight container, add 2.0 mL of water, shake well to make homogeneous, and allow to stand for more than 2 hours.

**Neutral detergent** Synthetic detergent containing anionic or non-ionic surfactant, and pH of its 0.25% solution is between 6.0 and 8.0. Dilute to a suitable concentration before use.

**Neutralized ethanol** See ethanol, neutralized.

**Neutral red** C_{18}H_{17}N_{4}Cl Slightly metallic, dark green powder or masses.

**Identification**—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>: it exhibits absorption at the wave numbers of about 3310 cm⁻¹, 3160 cm⁻¹, 1621 cm⁻¹, 1503 cm⁻¹, 1323 cm⁻¹, 1199 cm⁻¹ and 732 cm⁻¹.

**Neutral red TS** Dissolve 0.1 g of neutral red in acetic acid (100) to make 100 mL.

**Nicardipine hydrochloride for assay** C_{26}H_{29}N_{3}O_{6}.HCl [Same as the monograph Nicardipine Hydrochloride. When dried, it contains not less than 99.0% of nicardipine hydrochloride (C_{26}H_{29}N_{3}O_{6}.HCl).]

**Nicergoline for assay** C_{24}H_{26}BrN_{3}O_{3} [Same as the monograph Nicergoline, or Nicergoline purified according to the method below. When dried, it contains not less than 99.0% of nicergoline (C_{24}H_{26}BrN_{3}O_{3}), and when perform the test of the Purity (2) under Nicergoline, the total area of the peaks other than nicergoline from the sample solution is not more than 2.5 times the peak area of nicergoline from the standard solution.

Method of purification: Dissolve 1 g of Nicergoline in 20 mL of acetonitrile, allow to stand in a dark place for about 36 hours, filter, and dry the crystals so obtained at 60°C for 2 hours in vacuum.]

**Nicomol for assay** C_{16}H_{12}N_{4}O [Same as the monograph Nicomol. When dried, it contains not less than 99.0% of C_{16}H_{12}N_{4}O_{3}.]

**Nicotinamide** C_{6}H_{6}N_{2}O [Same as the namesake monograph]

**β-Nicotinamide adenine dinucleotide (β-NAD)** C_{21}H_{27}N_{7}O_{14}P_{2} [K 9802]

**Content:** not less than 94.5%. **Assay:**—Weigh accurately about 25 mg of β-nicotinamide-adenine dinucleotide, oxidized form, and dissolve in water to make exactly 25 mL. Pipet 0.2 mL of this solution, add 0.1 mol/L phosphate buffer solution, pH 7.0, to make exactly 10 mL, and use this solution as the sample solution. Determine the absorbances, A_1 and A_0, of the sample solution and 0.1 mol/L phosphate buffer solution, pH 7.0, at 260 nm as directed under Ultraviolet-visible Spectrophotometry <2.24>, using water as the blank.

\[
\text{Amount (mg) of } C_{21}H_{27}N_{7}O_{14}P_{2} = \frac{0.6634 \times 10}{17.6 \times 0.20} \times (A_1 - A_0) \times 25
\]

**β-Nicotinamide adenine dinucleotide TS** Dissolve 40 mg of β-nicotinamide adenine dinucleotide, oxidized form in 10 mL of water. Prepare before use.

**Nifedipine** C_{17}H_{14}N_{2}O_{6} [Same as the namesake monograph]

**Nile blue** C_{29}H_{32}ClIN_{2}O Blue-green powder.

**Ninhydrin** C_{6}H_{6}N_{2}O [K 8870, Special class]

**Ninhydrin TS** Dissolve 0.2 g of ninhydrin in water to make 10 mL. Prepare before use.

**Ninhydrin-acetic acid TS** Dissolve 1.0 g of ninhydrin in 50 mL of ethanol (95), and add 10 mL of acetic acid (100).

**Ninhydrin-tartric acid-acetic acid TS** Dissolve 70 g of citric acid, monohydrate in 500 mL of water, add 58 mL of acetic acid (100), 70 mL of a solution of sodium hydroxide (21 in 50) and water to make 1000 mL. In 100 mL of this solution dissolve 0.2 g of ninhydrin.

**Ninhydrin-stannous chloride TS** See ninhydrin-tin (II) chloride TS.

**Ninhydrin-sulfuric acid TS** Dissolve 0.1 g of ninhydrin in 100 mL of sulpheric acid. Prepare before use.

**Ninhydrin-tartric acid-chloride TS** Dissolve 21.0 g of citric acid in water to make 200 mL, adjust the pH to 5.6 ± 0.2 by adding sodium hydroxide TS, add water to make 500 mL, and dissolve 1.3 g of tin (II) chloride. To 50 mL of the solution, add 50 mL of a 2-methoxethanol solution of ninhydrin (2 in 50). Prepare before use.

**0.2% Ninhydrin-water saturated 1-butanol TS** Dissolve 2 g of ninhydrin in 1-butanol saturated with water to make 1000 mL.

**Nitrendipine for assay** [Same as the monograph Nitrendipine. It, when dried, contains not less than 99.0% of nitrendipine (C_{20}H_{20}ClN_{3}O_{6}) and meets the following requirement. When perform the test as directed in the Purity (2) under Nitrendipine, the area of the peak of nitrendipine from the standard solution, and the area of the peak other than nitrendipine and the dimethyl ester is not larger than 1/2 times the peak area of nitrendipine from the standard solution, and the total area of the peak other than nitrendipine is not larger than 1/2 times the peak area of nitrendipine from the standard solution.]

**Nitric acid** HNO_{3} [K 8541, Special class, Concentration: 69 – 70%, Density: about 1.42 g/mL]

**Nitric acid, dilute** Dilute 10.5 mL of nitric acid with water to make 100 mL (10%).

**Nitric acid, fuming** [K 8739, Special class, Concentration: not less than 97%, Density: 1.52 g/mL]

**Nitric acid TS, 2 mol/L** Dilute 12.9 mL of nitric acid...
with water to make 100 mL.

2',2'-2'-Nitrolitriethanol  \((\text{CH}_2\text{CH}_2\text{OH})_3\text{N}\)  [K 8663, Special class]

2',2'-2'-Nitrolitriethanol buffer solution, pH 7.8
Dissolve 149.2 g of 2',2',2'-nitrolitriethanol in about 4500 mL of water, adjust to pH 7.8 with diluted 6 mol/L hydrochloric acid TS (2 in 3), and add water to make 5000 mL.

3-Nitroaniline  \(\text{C}_6\text{H}_5\text{NO}_2\)  Yellow crystals or crystalline powder.
**Melting point** <2.60>: 112 – 116°C

4-Nitroaniline  \(\text{C}_6\text{H}_4\text{NO}_2\)  Yellow to yellowish-red crystals or crystalline powder.
**Melting point** <2.60>: 147 – 150°C. Preserve in a light-resistant tight container.

p-Nitroaniline  See 4-nitroaniline.

p-Nitroaniline-sodium nitrite TS  See 4-nitroaniline-sodium nitrite TS.

3-Nitroaniline-sodium nitrite TS  To 90 mL of a solution of 0.3 g of 4-nitroaniline in 100 mL of 10 mol/L hydrochloric acid TS add 10 mL of a solution of sodium nitrite (1 in 20), and mix well. Prepare before use.

O-Nitrobenzaldehyde  See 2-nitrobenzaldehyde.

2-Nitrobenzaldehyde  \(\text{O}_2\text{NC}_6\text{H}_4\text{CHO}\)  Pale yellow crystals or crystalline powder.
**Melting point** <2.60>: 42 – 44°C

Nitrobenzene  \(\text{C}_6\text{H}_5\text{NO}_2\)  [K 8723, Special class]

p-Nitrobenzenediazonium chloride TS  See 4-nitrobenzenediazonium chloride TS.

4-Nitrobenzenediazonium chloride TS  To 90 mL of a solution of 0.3 g of 4-nitroaniline in 100 mL of 10 mol/L hydrochloric acid TS add 10 mL of a solution of sodium nitrite (1 in 20), and mix well. Prepare before use.

p-Nitrobenzenediazonium chloride TS for spraying  See 4-nitrobenzenediazonium chloride TS for spraying.

4-Nitrobenzenediazonium chloride TS for spraying  Dissolve 1.1 g of 4-nitroaniline in 1.5 mL of hydrochloric acid, add 1.5 mL of water, and then add a solution prepared by dissolving 0.5 g of sodium nitrite in 5 mL of water, while cooling in an ice bath. Prepare before use.

p-Nitrobenzenediazonium fluoride TS  See 4-nitrobenzenediazonium fluoride TS.

4-Nitrobenzenediazonium fluoride TS  Dissolve 1.1 g of 4-nitroaniline in 1.5 mL of hydrochloric acid, add 1.5 mL of water, and then add a solution prepared by dissolving 0.5 g of sodium nitrite in 5 mL of water, while cooling in an ice bath. Prepare before use.

p-Nitrobenzenediazonium fluoride TS for spraying  See 4-nitrobenzenediazonium fluoride TS for spraying.

4-Nitrobenzenediazonium fluoride TS for spraying  Dissolve 0.4 g of 4-nitroaniline in 60 mL of 1 mol/L hydrochloric acid TS, and add, while cooling in an ice bath, sodium nitrite TS until the mixture turns potassium iodide-starch paper to blue in color. Prepare before use.

p-Nitrobenzenediazonium hydrochloride  See 4-nitrobenzenediazonium hydrochloride.

4-Nitrobenzenediazonium hydrochloride  \(\text{O}_2\text{NC}_6\text{H}_4\text{NBF}_4\)  Pale yellowish white, almost odorless powder. Freely soluble in dilute hydrochloric acid, slightly soluble in water, and very slightly soluble in ethanol (95) and in chloroform. Melting point: about 148°C (with decomposition).

**Identification**—Add 1 mL each of a solution of phenol (1 in 1000) and sodium hydroxide TS to 10 mL of a solution of 4-nitrobenzenediazonium hydrochloride (1 in 1000): a red color develops.

**Loss on drying** <2.41>: not more than 1.0% (1 g, silica gel, 2 hours).

p-Nitrobenzoyl chloride  See 4-nitrobenzoyl chloride.

4-Nitrobenzoyl chloride  \(\text{O}_2\text{NC}_6\text{H}_4\text{COCl}\)  Light yellow crystals.
**Melting point** <2.60>: 70 – 74°C

**Content**: not less than 98.0%. Assay—Weigh accurately about 0.5 g of 4-nitrobenzoyl chloride, add an excess of silver nitrate-ethanol TS, and boil under a reflux condenser for 1 hour. After cooling, filter the precipitate, wash with water, dry at 105°C to constant mass, and weigh. The mass of 4-nitrobenzoyl chloride, multiplied by 1.107, represents the mass of 4-nitrobenzoyl chloride (\(\text{C}_6\text{H}_4\text{CINO}_3\)).

p-Nitrobenzyl chloride  See 4-nitrobenzyl chloride.

4-Nitrobenzyl chloride  \(\text{O}_2\text{NC}_6\text{H}_4\text{CHCl}\)  Light yellow crystals or crystalline powder. Soluble in ethanol (95).
**Melting point** <2.60>: 71 – 73°C

**Content**: not less than 98.0%. Assay—Weigh accurately about 0.5 g of 4-nitrobenzyl chloride, add 15 mL of a solution prepared by dissolving 4 g of silver nitrate in 10 mL of water and adding ethanol (95) to make 100 mL, and heat on a water bath under a reflux condenser for 1 hour. After cooling, filter the precipitate with a glass filter, wash with water, dry at 105°C to constant mass, and weigh. The mass of the precipitate represents the amount of silver chloride (AgCl: 143.32).

Amount (mg) of 4-nitrobenzyl chloride
= amount (mg) of silver chloride (AgCl: 143.32) \(\times\) 1.197

4-(4-Nitrobenzy1)pyridine  \(\text{C}_6\text{H}_4\text{NO}_2\)  Pale yellow, crystalline powder. Freely soluble in acetone, and soluble in ethanol (95).
**Melting point** <2.60>: 69 – 71°C

**Nitroethane**  \(\text{C}_2\text{H}_5\text{NO}_2\)  
**Density** <2.50>: 1.048 – 1.053 g/cm\(^3\) (20°C) 
**Water** <2.48>: not more than 0.1%.

**Nitrogen**  [Same as the namesake monograph]

Nitrogen monoxide  NO  A colorless gas. Prepare by adding sodium nitrite TS to a solution of iron (II) sulfate heptahydrate in dilute sulfuric acid. Nitrogen monoxide from a metal cylinder may be used.

Nitromethane  \(\text{CH}_3\text{NO}_2\)  [K 9523, Special class]

3-Nitrophenol  \(\text{C}_6\text{H}_4\text{NO}_3\)  A light yellow crystalline powder.
**Melting point** <2.60>: 96 – 99°C

4-Nitrophenol  \(\text{C}_6\text{H}_4\text{NO}_3\)  [K 8721, Special class]

o-Nitrophenyl-β-D-galactopyranoside  See 2-nitrophenyl-β-D-galactopyranoside.

2-Nitrophenyl-β-D-galactopyranoside  \(\text{C}_6\text{H}_4\text{NO}_3\)  White crystalline powder. Odorless. It is sparingly soluble in water, slightly soluble in ethanol (95), and practically insoluble in diethyl ether.
**Melting point** <2.60>: 193 – 194°C

**Purity** Clarity and color of solution—A solution of 2-nitrophenyl-β-D-galactopyranoside (1 in 100) is clear and colorless.

**Loss on drying** <2.41>: not more than 0.1% (0.5 g, 105°C, 2 hours).

**Content**: not less than 98.0%. Assay—Weigh accurately
about 0.05 g of 2-nitrophenyl-β-D-galactopyranoside, previously dried, dissolve in water to make exactly 100 mL. Pipet 20 mL of this solution, and add water to make exactly 50 mL. Determine the absorbance, A, of this solution at 262 nm as directed under Ultraviolet-visible Spectrophotometry 2.24:

\[
A = \frac{\text{Amount (mg) of 2-nitrophenyl-β-D-galactopyranoside}}{133} \times 25,000
\]

1-Nitroso-2-naphthol C_{10}H_{7}NO_{2} 
A yellow-brown to red crystalline powder.

Melting point < 260°: 106 – 110°C.
Preserve in a light-resistant tight container.

1-Nitroso-2-naphthol TS Dissolve 0.06 g of 1-nitroso-2-naphthol in 80 mL of acetic acid (100), and add water to make 100 mL.

α-Nitroso-β-naphthol See 1-nitroso-2-naphthol.

α-Nitroso-β-naphthol TS See 1-nitroso-2-naphthol TS.

Nitrous oxide N_{2}O Colorless and odorless gas. Use nitrous oxide from a metal cylinder.

Cells derived from mouse NK cells.

NN Indicator Mix 0.5 g of 2-hydroxy-1-(2′-hydroxy-4′-sulfo-1′-naphthylazo)-3-naphthoic acid with 50 g of anhydrous sodium sulfate, and triturate until the mixture becomes homogeneous.

Nodakenin for thin-layer chromatography C_{20}H_{24}O_{9}
White powder. Slightly soluble in water and in methanol, and very slightly soluble in ethanol (99.5). Melting point: about 220°C (with decomposition).

Identification—Determine the absorption spectrum of a solution of nodakenin for thin-layer chromatography in methanol (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry 2.24; it exhibits a maximum between 333 nm and 337 nm.

Optical rotation < 2.49° [α]_{D}^{20}: +50 – +68° (5 mg, methanol, 10 mL, 100 mm).

Purity Related substances—Dissolve 1 mg of nodakenin for thin-layer chromatography in 3 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Proceed with 5 μL each of these solutions as directed in the Identification (2) under Peucedanum Root: the spot other than the principal spot of around Rf value of 0.3 from the sample solution is not more intense than the spot from the standard solution.

Nonylphenoxypoly(ethylenoxy)ethanol for gas chromatography Prepared for gas chromatography.

Normal agar media for teceleukin Dissolve 5.0 g of meat extract, 10.0 g of peptone, 5.0 g of sodium chloride, and 15.0 to 20.0 g of agar in water to make 1000 mL, and sterilize. Adjust the pH to 6.9 to 7.1.

n-Octadecane C_{18}H_{38}
Colorless or white solid at ordinary temperature.

Purity Clarity of solution—A solution of n-octadecane in chloroform (1 in 25) is clear.

Octadecylsilanized silica gel for pretreatment Prepared for pretreatment.

n-Octane C_{8}H_{18}

Specific gravity < 2.56* d_{20}^{20}: 0.700 – 0.705

Purity—Perform the test with 2 μL of n-octane as directed under Gas Chromatography 2.02 according to the conditions in the Assay under Hypromellose. Measure each peak area by the automatic integration method, and calculate the amount of n-octane by the area percentage method: not less than 99.0%.

Octane, iso A colorless liquid. Practically insoluble in water. Miscible with diethyl ether and with chloroform.

Purity—Determine the absorbances of isooctane at 230 nm, 250 nm and 280 nm as directed under Ultraviolet-visible Spectrophotometry 2.24, using water as the blank solution: these values are not more than 0.050, 0.010 and 0.005, respectively.

1-Octanol CH_{3}(CH_{2})_{2}CH_{2}OH [K 8213, Special class]
Octyl alcohol See 1-octanol.

n-Octylbenzene C_{10}H_{12} Clear and colorless liquid, having a characteristic odor.
Specific gravity < 2.56* d_{20}^{20}: 0.854 – 0.863
Distillation test < 2.57°: 263 – 265°C, not less than 95 vol%.

Ofl oxacin C_{18}H_{36}FN_{3}O_{4} [Same as the namesake monograph]

Ofo l oxacin demethyl substance (±)-9-Fluoro-2,3-dihydro-3-methyl-7-oxo-7H-10-(1-piperaziny1)-pirido[1, 2, 3-de] [1, 4]benzoxazine-6-carboxylic acid C_{17}H_{16}FN_{3}O_{4} White to light green-yellowish white, crystals or crystalline powder.

Identification—Determine the infrared absorption spectrum of ofloxacin demethyl substance as directed in the potassium bromide disk method under Infrared Spectrophotometry 2.25; it exhibits absorption at the wave numbers of about 3050 cm\(^{-1}\), 2840 cm\(^{-1}\), 1619 cm\(^{-1}\), 1581 cm\(^{-1}\), 1466 cm\(^{-1}\), 1267 cm\(^{-1}\), 1090 cm\(^{-1}\), 1051 cm\(^{-1}\) and 816 cm\(^{-1}\).

Oleic acid C_{18}H_{32}O
Occurs as a colorless or pale yellow transparent liquid and has a slightly distinct odor. It is miscible with ethanol (95) and with diethyl ether, and practically insoluble in water.

Specific gravity < 2.56* d_{20}^{20}: about 0.9

Content: not less than 99.0%. Assay—To 40 μL of oleic acid to be examined add 1 mL of a solution of boron trifluoride in methanol (3 in 20), mix, and heat on a water bath for 3 minutes. After cooling, add 10 mL of petroleum ether and 10 mL of water, shake, collect the ether layer after allowing to stand, and use as the sample solution. Perform the test with 0.2 μL of the sample solution as directed under Gas Chromatography 2.02 according to the following conditions, determine each peak area by the automatic integration method, and calculate the amount of methyl oleate by the area percentage method.

Operating conditions
Detector: A hydrogen flame-ionization detector
Column: A glass column 3 mm in inside diameter and 2 m in length, packed with siliceous earth for gas chromatography (149 – 177 μm) coated with methyl polyacrylate in a rate of 5 – 10%.

Column temperature: A constant temperature of about 220°C.
Carrier gas: Helium.
Flow rate: Adjust the flow rate so that the retention time of methyl oleate is about 10 minutes.
Time span of measurement: About 2 times as long as the retention time of methyl oleate, beginning after the solvent peak.

**Olive oil** [Same as the namesake monograph]

**Ophiopogon tuber** [Same as the namesake monograph]

**Orcine** C₉H₉O₃ White to light red-brown crystals or crystalline powder, having an unpleasant, sweet taste. It turns to red in color when oxidized in air. Soluble in water, in ethanol (95), and in diethyl ether.

*Melting point* 93 – 94°C

**Orcine-ferric chloride TS** See orcine-iron (III) chloride TS.

**Orcine-iron (III) chloride TS** Dissolve 10 mg of orcine in 1 mL of a solution of iron (III) chloride hexahydrate in hydrochloric acid (1 in 1000). Prepare before use.

**Ordinary agar medium** Dissolve 25 to 30 g of agar in 1000 mL of ordinary broth with the aid of heat, add water to make up for the loss, adjust the pH to between 6.4 and 7.0, and filter. Dispense the filtrate, and sterilize by autoclaving. When powdered agar is used, 15 to 20 g of it is dissolved.

**Ordinary broth** Dissolve 5 g of beef extract and 10 g of peptone in 1000 mL of water by gentle heating. Adjust the pH of the mixture between 6.4 and 7.0 after sterilization, cool, add water to make up for the loss, and filter. Sterilize the filtrate by autoclaving for 30 minutes at 121°C.

**Osthole for thin-layer chromatography** C₁₅H₁₄O₂ A white crystalline powder, having no odor. Freely soluble in methanol and in ethyl acetate, soluble in ethanol (99.5), and practically insoluble in water. Melting point: 83 – 84°C.

**Purity** Related substances—Dissolve 1.0 mg of osthole for thin-layer chromatography in 1 mL of methanol. Perform the test with 10 μL of this solution as directed in the Identification under Cnidium Monnieri Fruit: on spot appears other than the principal spot at around Rf 0.3.

**Oxalate pH standard solution** See pH Determination <2.54>.

Oxalic acid See oxalic acid dihydrate.

**Oxalic acid dihydrate** H₂C₂O₄·2H₂O [K 8519, Special class]

**Oxalic acid TS** Dissolve 6.3 g of oxalic acid dihydrate in water to make 100 mL (0.5 mol/L).

**Oxycodone hydrochloride for assay** See oxycodone hydrochloride hydrate for assay.

**Oxycodone hydrochloride hydrate for assay** C₁₈H₂₁NO₄·HCl·3H₂O [Same as the monograph Oxycodone Hydrochloride Hydrate. It contains not less than 99.0% of oxycodone hydrochloride (C₁₈H₂₁NO₄·HCl), calculated on the anhydrous basis.]

**Oxygen** O₂ [K 1101]

**2-Oxy-1-(2′-oxy-4′-sulfo-1′-naphthylazo)-3-naphthoic acid** See 2-hydroxy-1-(2′-hydroxy-4′-sulfo-1′-naphthylazo)-3-naphthoic acid.

**8-Oxyquinoline** See 8-quinolinol.

**Oxytocin** C₄₃H₆₆N₁₂O₁₂S₂ [Same as the namesake monograph]

**Paeonol for assay** C₉H₁₀O₃ Use paeonol for thin-layer chromatography meeting the following additional specifications.

**Purity** Related substances—Dissolve 5.0 mg of paeonol for assay in 50 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution (1). Perform the test with exactly 10 μL each of the sample solution and standard solution (1) as directed under Liquid Chromatography <2.01> according to the following conditions, and measure each peak area of these solutions by the automatic integration method: the total area of the peaks other than paeonol from the sample solution is not larger than the peak area of paeonol from the standard solution (1).

**Operating conditions**
Proceed the operating conditions in the Assay under Moutan Bark except detection sensitivity and time span of measurement.

**Detection sensitivity** Pipet 1 mL of the standard solution (1), add the mobile phase to make exactly 20 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of paeonol obtained from 10 μL of the standard solution (2) can be measured, and the peak height of paeonol from 10 μL of the standard solution (1) is about 20% of the full scale.

**Time span of measurement** About 3 times as long as the retention time of paeonol beginning after the solvent peak.

**Paeonol for component determination** See paeonol for assay.

**Paeonol for thin-layer chromatography** C₉H₁₀O₃ White, crystals or crystalline powder, having a specific odor. Freely soluble in methanol and in diethyl ether, and slightly soluble in water. Melting point: about 50°C

**Purity** Related substances—Dissolve 1.0 mg of paeonol for thin-layer chromatography in exactly 1 mL of methanol, and perform with 20 μL of this solution as directed in the Identification (2) under Peony Root: any spot other than the principal spot at the Rf value of about 0.3 does not appear.

**Palladium chloride** See palladium (II) chloride.

**Palladium chloride TS** See palladium (II) chloride TS.

**Palladium (II) chloride** PdCl₂ [K 8154, Special class]
Palladium (II) chloride TS  Dissolve 0.2 g of palladium (II) chloride in 500 mL of 0.25 mol/L sulfuric acid TS, by heating if necessary, cool, and add 0.25 mol/L sulfuric acid TS to make 1000 mL.

Palmitin chloride C_{20}H_{21}NO_4 \cdot HCl A yellow-brown crystalline powder.

Purity—Dissolve 1 mg of palmitin chloride in 10 mL of methanol, and use this solution as the sample solution. Proceed with 20 μL of the sample solution as directed in the Assay under Phellodendron Bark: when measure the peak areas 2 times as long as the retention time of palmitin, the total area of the peaks other than palmitin is not larger than 1/10 of the total area except the area of solvent peak.

Palmitic acid for gas chromatography C_{16}H_{32}O_2

<td>Perillaldehyde for assay Perillaldehyde for thin-layer chromatography meeting the following specifications.</td>
</tr>
<tr>
<td>Absorbance &lt;2.24° E_{1%}^{230} (230 nm): 850 – 950 (10 mg, methanol, 2000 mL).</td>
</tr>
<tr>
<td>Purity Related substances—Dissolve 10 mg of perillaldehyde in 250 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL of each of the sample solution and standard solution as directed under Liquid Chromatography &lt;2.01&gt; according to the following conditions. Determine each peak from both solutions by the automatic integration method: the total area of the peaks other than the peak of perillaldehyde from the sample solution is not larger than the peak of perillaldehyde from the standard solution.</td>
</tr>
<tr>
<td>Operating conditions</td>
</tr>
<tr>
<td>Detector, column, column temperature, mobile phase and flow rate: Proceed as directed in the operating conditions in the Assay under Perilla Herb.</td>
</tr>
<tr>
<td>Time span of measurement: About 3 times as long as the retention time of perillaldehyde beginning after the solvent peak.</td>
</tr>
<tr>
<td>System suitability</td>
</tr>
</tbody>
</table>
| Test for required detectability: Pipet 1 mL of the standard
solution, and add methanol to make exactly 20 mL. Confirm that the peak area of perillaldehyde obtained from 10 μL of this solution is equivalent to 3.5 to 6.5% of that of perillaldehyde from 10 μL of the standard solution.

System performance and system repeatability: Proceed as directed in the system suitability in the Assay under Perilla Herb.

**Perillaldehyde for component determination**  See perillaldehyde for assay.

**Perillaldehyde for thin-layer chromatography** C₁₀H₁₄O₃ Colorless to light brown transparent liquid, having a characteristic odor. Miscible with methanol and with ethanol (99.5), and very slightly soluble in water.

**Identification**—Determine the infrared absorption spectrum of perillaldehyde for thin-layer chromatography as directed in the liquid film method under Infrared Spectrophotometry 2.25: it exhibits absorption at the wave numbers of about 3080 cm⁻¹, 2930 cm⁻¹, 1685 cm⁻¹, 1644 cm⁻¹, 1435 cm⁻¹ and 890 cm⁻¹.

**Purity** Related substances—Dissolve 1.0 mg of perillaldehyde for thin-layer chromatography in 10 mL of methanol, and perform the test with 10 μL of this solution as directed in the Identification under Perilla Herb: no spot other than the principal spot at around RT value of 0.5 appears.

**Peroxidase** Obtained from horse-radish. A red-brown powder. It is freely soluble in water. It contains about 250 units per mg. One unit indicates an amount of the enzyme powder. It is freely soluble in water. It contains about 250

**Peroxidase-labeled antibody stock solution** 1 w/v% bovine serum albumin-phosphate buffer-sodium chloride TS containing antibody fragment (Fab') bound to peroxidase.

**Peroxidase-labeled bradykinin** A solution of horseradish origin peroxidase-binding bradykinin in gelatin-phosphate buffer solution, pH 7.0. A colorless to light brown clear solution.

**Peroxidase-labeled bradykinin TS** To 0.08 mL of peroxidase-labeled bradykinin, 8 mg of sodium tetraborate decahydrate, 8 mg of bovine serum albumin and 0.8 mL of gelatin-phosphate buffer solution, pH 7.0 add water to make 8 mL, and lyophilize. Dissolve this in 8 mL of water. Prepare before use.

**Peroxidase-labeled rabbit anti-ECP antibody Fab' TS** Mix 1 volume of ECP standard substance (equivalent to about 1 mg of protein) and 1 volume of Freund's complete adjuvant, and then immunize rabbits subcutaneously in the back region and intramuscularly in the hind leg muscle with this solution 5 times at 2 week intervals. Harvest blood on the 10th day after completing the immunization to obtain rabbit antisemur. Rabbit anti-ECP antibody Fab' is obtained by preparing an immobilzed ECP column in which ECP standard substance is bound to agarose gel and then purifying by affinity column chromatography to obtain rabbit anti-ECP antibody which undergoes pepsin digestion to yield Fab'; which is reacted with 2-aminoethanethiol hydrochloride.

Horseradish peroxidase is reacted with maleimido reagent [4-(maleimidomethyl) cyclohexyl carbonic acid-N-hydroxy-succinimide imidoester] to yield maleimido peroxidase. Perform a coupling reaction by mixing rabbit anti-ECP antibody Fab' and maleimido peroxidase at 4°C to prepare peroxidase-labeled rabbit anti-ECP antibody Fab'. Take a specific amount of peroxidase-labeled rabbit anti-ECP antibody Fab' and dilute using PBS containing bovine serum albumin. The peroxidase-labeled rabbit anti-ECP antibody Fab' TS is a diluted solution with a concentration that gives a good calibration curve with assay characteristics.

**Description** Clear and colorless solution

**Identification** Pipet 100 μL of the TS to be examined into flat-bottomed microtest plates. When substrate buffer solution for celmoleukin is added to this, it immediately exhibits a dark violet color, which changes to yellowish-red with time.

**Perphenazine maleate for assay** C₂₁H₂₆ClN₃OS.2C₄H₄O₄ [Same as the monograph Perphenazine Maleate. When dried, it contains not less than 99.0% of perphenazine maleate (C₂₁H₂₆ClN₃OS.2C₄H₄O₄).]

**Pethidine hydrochloride for assay** C₁₉H₂₃NO₂.HCl [Same as the monograph Pethidine Hydrochloride. When dried, it contains not less than 99.0% of pethidine hydrochloride C₁₉H₂₃NO₂.HCl.]

**Petrolatum** [Same as the monograph Yellow Petroleum or White Petrolatum]

**Petroleum benzine** [K 8594, Special class]

**Petroleum ether** [K 8593, Special class]

**Phenacetin** C₁₀H₁₃NO₂ White crystals or crystalline powder. Soluble in ethanol (95), and very slightly soluble in water.

**Melting point** 2.60°: 134 – 137°C

**Loss on drying** 2.41°: not more than 0.5% (1 g, 105°C, 2 hours).

**o-Phenanthroline** See 1,10-phenanthroline monohydrate.

**o-Phenanthroline hydrochloride** See 1,10-phenanthroline chloride monohydrate.

**1,10-Phenanthroline monohydrate** C₁₂H₉N₂.H₂O [K 8789, Special class]

**1,10-Phenanthroline TS** See 1,10-phenanthroline TS.

**1,10-Phenanthroline monohydrate** Dissolve 0.15 g of 1,10-phenanthroline monohydrate in 10 mL of a freshly prepared ferrous sulfate heptahydrate solution (37 in 2500) and 1 mL of dilute sulfuric acid. Preserve in tightly stoppered containers.

**1,10-Phenanthroline chloride monohydrate** C₁₂H₉N₂Cl.H₂O [K 8202, Special class]

**Phenethyline hydrochloride** C₁₀H₁₅CH₂NH₂.HCl White crystals or crystalline powder.

**Melting point** 2.60°: 220 – 225°C

**Phenobarbital for assay** C₁₂H₁₂N₂O₃ [Same as the monograph Phenobarbital]

**Phenol** C₆H₅OH [K 8798, Special class]

**Phenol for assay** C₆H₅OH [K 8798, Phenol, Special class]

**Phenol-hydrochloric acid TS** Dissolve 0.2 g of phenol in
10 mL of 6 mol/L hydrochloric acid TS.

**Phenolphthalein** $C_{19}H_{14}O_5S$ [K 8799, Special class]

**Phenolphthalein-thymol blue TS** Solution A: Dissolve 0.1 g of phenolphthalein in diluted ethanol (99.5%) (4 in 5). Solution B: Dissolve 0.1 g of thymol blue in 50 mL of a mixture of ethanol and dilute sodium hydroxide TS, add water to make 100 mL. Mix 2 volumes of solution A and 3 volumes of solution B before use.

**Phenolphthalein TS** Dissolve 1 g of phenolphthalein in 100 mL of ethanol (95).

**Phenolphthalein TS, alkaline** See Alcohol Number Determination <1.01>.

**Phenol red** $C_{19}H_{14}O_5S$ [K 8800, Special class]

**Phenol red TS** Dissolve 0.1 g of phenol red in 100 mL of ethanol (95), and filter if necessary.

**Phenol red TS, dilute** To 253 mL of a solution of ammonium nitrate (1 in 9400) add 105 mL of 2 mol/L sodium hydroxide TS and 135 mL of a solution prepared by dissolving 24 g of acetic acid (100) in water to make 200 mL. To this solution add 25 mL of a solution prepared by dissolving 33 mg of phenol red in 1.5 mL of 2 mol/L sodium hydroxide TS and adding water to make 100 mL. If necessary, adjust the pH to 4.7.

**Phenol-sodium nitroprusside TS** See phenol-sodium pentacyanonitrosylferrate (III) TS.

**Phenol-sodium pentacyanonitrosylferrate (III) TS** Dissolve 5 g of phenol and 25 mg of sodium pentacyanorosylferrate (III) dihydrate in sufficient water to make 500 mL. Preserve in a dark, cold place.

**Phenolsulfonphthalein for assay** $C_{19}H_{14}O_5S$ [Same as the monograph Phenolsulfonphthalein. When dried, it contains not less than 99.0% of phenolsulfonphthalein ($C_{19}H_{14}O_5S$).]

**Phenylalanine** See L-phenylalanine.

**L-Phenylalanine** $C_9H_{11}NO_2$ [Same as the namesake monograph]

**Phenyl benzoate** $C_8H_6COOC_6H_5$ White crystals or crystalline powder, having a slight, characteristic odor. *Melting point* $<2.60^°$: 68 – 70°C

**Purity** Clarity of solution—Dissolve 1.0 g of phenyl benzoate in 20 mL of methanol: the solution is clear.

**25% Phenyl-25% cyanopropyl methyl polysiloxane polymer for gas chromatography** Prepared for gas chromatography.

**o-Phenylenediamine dihydrochloride** $H_2NC_6H_4NH_2\cdot2HCl$ White to pale yellow or pale red crystals or crystalline powder.

**Clarity**—a solution (1 in 20) is clear.

**Content**—not less than 98.0%. Assay—Weigh accurately about 0.15 g of o-phenylenediamine dihydrochloride, dissolve in 50 mL of water, and titrate $<2.50^°$ with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 9.053 mg of $H_2NC_6H_4NH_2\cdot2HCl$

**Phenylfluorone** $C_{19}H_{12}O_5$ [K 9547]

**Phenylfluorone-ethanol TS** Dissolve 50 mg of phenylfluorone in 10 mL of a mixture of ethanol (95) and diluted hydrochloric acid (1 in 3), and add thanol (95) to make exactly 500 mL.

**n-Phenylglycine** $C_6H_7NO_2$ White, crystals or crystalline powder. Slightly soluble in water. *Loss on drying* $<2.40^°$: not more than 0.5% (1 g, 105°C, 3 hours).

**Content**—not less than 98.5%. Assay—Weigh accurately about 0.3 g of n-phenylglycine, previously dried, dissolve in 3 mL of formic acid, add 50 mL of acetic acid (100), and titrate $<2.50^°$ with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 15.12 mg of $C_6H_7NO_2$

**Phenyldrazine** $C_6H_7NHNH_2$ Colorless or light yellow, clear liquid, having a faint aromatic odor.

**Phenyldrazine hydrochloride** See phenyldrazinium chloride.

**Phenyldrazine hydrochloride TS** See phenyldrazinium chloride TS.

**Phenyldrazinium chloride** $C_6H_7NHNH_2\cdotHCl$ [K 8203, Special class]

**Phenyldrazinium chloride TS** Dissolve 65 mg of phenyldrazinium chloride recrystallized from dilute ethanol, in 100 mL of a solution previously prepared by adding cautiously 170 mL of sulfuric acid to 80 mL of water.

**Phenyl isothiocyanate** $C_8H_9NO_2$ Prepared for amino acid analysis or biochemistry.

**1-phenyl-3-methyl-5-pyrazolone** See 3-methyl-1-phenyl-5-pyrazolone.

50% Phenyl-50% methyl polysiloxane for gas chromatography Prepared for gas chromatography.
35% Phenyl-methyl silicone polymer for gas chromatography Prepared for gas chromatography.

50% Phenyl-methyl silicone polymer for gas chromatography Prepared for gas chromatography.

65% Phenyl-methyl silicone polymer for gas chromatography Prepared for gas chromatography.

Phenylpiperazine hydrochloride See phenylpiperazine monohydrochloride.

Phenylpiperazine monohydrochloride C₁₅H₁₄N₂·HCl A white powder. Melting point: about 247°C (with decomposition).

Phenytoin for assay C₁₅H₁₂N₂O₂ [Same as the monograph Phenytoin. It meets the following requirements.]

Purity Related substances—Dissolve 25 mg of phenytoin for assay in 50 mL of the mobile phase, and use this solution as the sample solution. To exactly 1 mL of the sample solution add the mobile phase to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 10 µL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine each peak area by the automatic integration method: the total peak area of phenytoin obtained from the standard solution is not less than 1.5 times that with phenytoin obtained from the sample solution.

Retention time of phenytoin, beginning after the solvent peak.

Operating conditions
Detector: An ultraviolet absorption photometer (wavelength: 220 nm).
Column, column temperature, and flow rate: Proceed as directed in the operating conditions in the Assay under Phenytoin.
Mobile phase: A mixture of 0.02 mol/L phosphate buffer solution, pH 3.5 and acetonitrile for liquid chromatography (11:9).

Time span of measurement: About 5 times as long as the retention time of phenytoin, beginning after the solvent peak.

System suitability
Test for required detectability: To exactly 2 mL of the standard solution add the mobile phase to make exactly 20 mL. Confirm that the peak area of phenytoin obtained from 10 µL of this solution is equivalent to 8 to 12% of that with 10 µL of the standard solution.

System performance: When the procedure is run with 10 µL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of phenytoin are not less than 6000 and not more than 2.0, respectively.

System repeatability: When the test is repeated 6 times with 10 µL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of phenytoin is not more than 2.0%.

Phloroglucin See phloroglucinol dihydrate.

Phloroglucin dihydrate See phloroglucinol dihydrate.

Phloroglucinol dihydrate C₆H₃(OH)₃·2H₂O White to pale yellow, crystals or crystalline powder. Melting point <2.60>: 215 – 219°C (after drying). Loss on drying <2.41>: 18.0 – 24.0% (1 g, 105°C, 1 hour).

Phosphatase, alkaline Obtained from bovine small intestine. A white to grayish white or yellowish brown, lyophilized powder. It contains about 1 Units per mg, not containing any saline. One unit indicates an amount of the enzyme which produces 1 µmol of 4-nitrophenol at 37°C and pH 9.8 in 1 minute from 4-nitrophenyl phosphate used as the substrate.

Phosphatase TS, alkaline Dissolve 0.1 g of alkaline phosphatase in 10 mL of boric acid-magnesium chloride buffer solution, pH 9.0. Prepare before use.

Phosphate-buffered sodium chloride TS Dissolve 8.0 g of sodium chloride, 0.2 g of potassium chloride, 2.9 g of disodium hydrogen phosphate dodecahydrate, and 0.2 g of potassium dihydrogen phosphate in water to make 1000 mL.

0.01 mol/L Phosphate buffer-sodium chloride TS, pH 7.4 Dissolve 2.93 g of disodium hydrogen phosphate dodecahydrate (NaH₂PO₄·12H₂O), 0.25 g of potassium dihydrogen phosphate (KH₂PO₄), and 9.0 g of sodium chloride in water to make 1000 mL.

Phosphate buffer solution for assay of bupleurum root To 100 mL of 0.2 mol/L potassium dihydrogen phosphate TS add 59 mL of sodium hydrogen phosphate TS.

Phosphate buffer solution for component determination of bupleurum root See phosphate buffer solution for assay of bupleurum root.

Phosphate buffer solution for microplate washing Dissolve 0.62 g of sodium dihydrogen phosphate dihydrate, 9.48 g of disodium hydrogen phosphate dodecahydrate (NaH₂PO₄·12H₂O), 0.25 g of potassium dihydrogen phosphate (KH₂PO₄), and 9.0 g of sodium chloride in 1000 mL. Dilute this solution 10 times with water before use.

Phosphate buffer solution for pancreatin Dissolve 3.3 g of anhydrous disodium hydrogen phosphate, 1.4 g of potassium dihydrogen phosphate, and 0.33 g of sodium chloride in water to make 100 mL.

Phosphate buffer solution for processed aconite root Dissolve 19.3 g of disodium hydrogen phosphate dodecahydrate in 3660 mL of water, and add 12.7 g of phosphoric acid.

Phosphate buffer solution, pH 3.0 Dissolve 136 g of potassium dihydrogen phosphate in water to make 1000 mL, and adjust to pH 3.0 with phosphoric acid.

0.02 mol/L Phosphate buffer solution, pH 3.0 Dissolve 3.1 g of sodium dihydrogen phosphate in 1000 mL of water, and adjust the pH to 3.0 with dilute phosphoric acid (1 in 10).

Phosphate buffer solution, pH 3.1 Dissolve 136.1 g of potassium dihydrogen phosphate in 500 mL of water, and add 6.3 mL of phosphoric acid and water to make 1000 mL.

0.02 mol/L Phosphate buffer solution, pH 3.5 Dissolve 3.1 g of sodium dihydrogen phosphate dihydrate in 1000 mL of water, and adjust the pH to 3.5 with diluted phosphoric acid (1 in 10).

0.05 mol/L Phosphate buffer solution, pH 3.5 To 1000 mL of 0.05 mol/L potassium dihydrogen phosphate TS add a suitable amount of a solution of phosphoric acid (49 in
0.1 mol/L Phosphate buffer solution, pH 4.5  Dissolve 13.61 g of potassium dihydrogen phosphate in 750 mL of water, adjust to pH 4.5 with potassium hydroxide TS, and add water to make 1000 mL.

0.1 mol/L Phosphate buffer solution, pH 5.3  Dissolve 0.44 g of disodium hydrogen phosphate dodecahydrate and 13.32 g of potassium dihydrogen phosphate in 750 mL of water, adjust the pH to 5.3 with sodium hydroxide TS or phosphoric acid, and add water to make 1000 mL.

1/15 mol/L Phosphate buffer solution, pH 5.6  Mix 50 mL of 0.2 mol/L potassium dihydrogen phosphate in 750 mL of water, adjust to pH 5.6 with potassium hydroxide TS, and add water to make 1000 mL.

Phosphate buffer solution, pH 5.9  Dissolve 6.8 g of potassium dihydrogen phosphate in 800 mL of water, adjust the pH to 5.9 with diluted potassium hydroxide TS (1 in 10), and add water to make 1000 mL.

Phosphate buffer solution, pH 6.0  Dissolve 8.63 g of potassium dihydrogen phosphate and 1.37 g of anhydrous disodium hydrogen phosphate in 750 mL of water, adjust the pH to 6.0 with sodium hydroxide TS or diluted phosphoric acid (1 in 15), and add water to make 1000 mL.

0.05 mol/L Phosphate buffer solution, pH 6.0  To 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution add 5.70 mL of 0.2 mol/L sodium hydroxide TS and water to make 200 mL.

Phosphate buffer solution, pH 6.2  Dissolve 9.08 g of potassium dihydrogen phosphate in 1000 mL of water (solution A). Dissolve 9.46 g of disodium hydrogen phosphate in 1000 mL of water (solution B). Mix 800 mL of the solution A and 200 mL of the solution B, and adjust the pH to 6.2 with the solution A or the solution B if necessary.

Phosphate buffer solution, pH 6.5  Mix 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution and 15.20 mL of 0.2 mol/L sodium hydroxide VS, and add water to make 200 mL.

Phosphate buffer solution for antibiotics, pH 6.5  Dissolve 10.5 g of disodium hydrogen phosphate dodecahydrate and 5.8 g of potassium dihydrogen phosphate in 750 mL of water, adjust the pH to 6.5 with sodium hydroxide TS, and add water to make 1000 mL.

Phosphate buffer solution, pH 6.8  Dissolve 3.40 g of potassium dihydrogen phosphate and 3.55 g of disodium hydrogen phosphate in water to make 1000 mL.

0.01 mol/L Phosphate buffer solution, pH 6.8  Dissolve 1.36 g of potassium dihydrogen phosphate in 900 mL of water, adjust the pH to 6.8 with 0.2 mol/L sodium hydroxide TS, and add water to make 1000 mL.

0.1 mol/L Phosphate buffer solution, pH 6.8  Dissolve 6.4 g of potassium dihydrogen phosphate and 18.9 g of disodium hydrogen phosphate dodecahydrate in about 750 mL of water, adjust the pH to 6.8 with sodium hydroxide TS if necessary, and add water to make 1000 mL.

Phosphate buffer solution, pH 7.0  Mix 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution and 29.54 mL of 0.2 mol/L sodium hydroxide VS, and add water to make 200 mL.

0.05 mol/L Phosphate buffer solution, pH 7.0  Dissolve 4.83 g of dipotassium hydrogen phosphate and 3.02 g of potassium dihydrogen phosphate in 1000 mL of water, and adjust to pH 7.0 with phosphoric acid or potassium hydroxide TS.

0.1 mol/L Phosphate buffer solution, pH 7.0  Dissolve 17.9 g of disodium hydrogen phosphate dodecahydrate in about 750 mL of water, adjust the pH to 7.0 with sodium hydroxide TS, and add water to make 1000 mL.

0.02 mol/L Phosphate buffer solution, pH 7.2  Mix 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution, and 46.1 mL of 0.2 mol/L sodium hydroxide VS, and add water to make 200 mL.

Phosphate buffer solution, pH 7.4  Mix 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution and 39.50 mL of 0.2 mol/L sodium hydroxide VS, and add water to make 200 mL.

0.03 mol/L Phosphate buffer solution, pH 7.5  Dissolve 4.083 g of potassium dihydrogen phosphate in 800 mL of water, adjust the pH to 7.5 with 0.2 mol/L sodium hydroxide TS, and add water to make 1000 mL.

Phosphate buffer solution, pH 8.0  Mix 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution, and 46.1 mL of 0.2 mol/L sodium hydroxide VS, and add water to make 1000 mL.

0.02 mol/L Phosphate buffer solution, pH 8.0  To 50 mL of 0.2 mol/L potassium dihydrogen phosphate TS for buffer solution add 300 mL of water, adjust the pH to 8.0 with sodium hydroxide TS, and add water to make 1000 mL.

0.1 mol/L Phosphate buffer solution, pH 8.0  Dissolve 13.2 g of anhydrous disodium hydrogen phosphate and 0.91 g of potassium dihydrogen phosphate in about 750 mL of water, adjust to pH 8.0 with phosphoric acid, and add water to make 1000 mL.

0.1 mol/L Phosphate buffer solution for antibiotics, pH 8.0  Dissolve 16.73 g of dipotassium hydrogen phosphate and 0.523 g of potassium dihydrogen phosphate in about 750 mL of water, adjust the pH to 8.0 with phosphoric acid, and add water to make 1000 mL.

0.2 mol/L Phosphate buffer solution, pH 10.5  Dissolve 34.8 g of dipotassium hydrogen phosphate in 750 mL of water, adjust to pH 10.5 with 8 mol/L sodium hydroxide TS, and add water to make 1000 mL.

Phosphate buffer solution, pH 12  To 5.44 g of disodium hydrogen phosphate add 36.5 mL of sodium hydroxide TS and 40 mL of water, dissolve by shaking well, and add water to make 100 mL.

Phosphinic acid H₃PO₂  Colorless or pale yellow viscous liquid.

Identification—(1) To 0.5 mL of phosphinic acid add 0.5 mL of hydrogen peroxide (30) and 0.5 mL of dilute sulfuric acid (1 in 6), and evaporate to nearly dryness on a
Reagents, Test Solutions / General Tests

Phosphoric acid See phosphoric acid n-hydrate.

Phosphotungstic acid See phosphotungstic acid n-hydrate.

Phosphotungstic acid n-hydrate \( \text{P}_2\text{O}_5.\text{WO}_3.n\text{H}_2\text{O} \)

White to yellowish green, crystals or crystalline powder.

Identification—To 5 mL of a solution in 10 mL of acidic tin (II) chloride TS, and heat: blue precipitates appear.

Phosphotungstic acid TS Dissolve 1 g of phosphotungstic acid n-hydrate in water to make 100 mL.

\( \text{C}_8\text{H}_4\text{O}_3 \) Light yellow to yellow crystals.

Content—Not less than 99%. Assay—Dissolve 1 g of \( \text{C}_8\text{H}_4\text{O}_3 \) in 10 mL of ethanol (95); Proceed with 2 \( \mu \)L of this solution as directed in Gas Chromatography \( <2.02 \) according to the following conditions, and determine each peak area by the automatic integration method.

Content % = peak area of \( \text{C}_8\text{H}_4\text{O}_3 \)/total area of all peaks \( \times 100 \)

Operating conditions

Detector: A thermal conductivity detector.

Column: A glass column 3 mm in inside diameter and 2 m in length, packed with siliconeous earth for gas chromatography treated with acid and silane (177 – 250 \( \mu \)m), coated with methyl silicon polymer for gas chromatography in 10%.

Column temperature: A constant temperature of about 180°C.

Carrier gas: Helium.

Flow rate: Adjust the flow rate so that the retention time of \( \text{C}_8\text{H}_4\text{O}_3 \) is 3 – 4 minutes.

Time span of measurement: About 7 times as long as the retention time of \( \text{C}_8\text{H}_4\text{O}_3 \), beginning after the solvent peak.

Phthalic anhydride \( \text{C}_8\text{H}_4\text{O}_3 \) White crystals or crystalline powder. Soluble in ethanol (95), sparingly soluble in water.

Sensitivity test—Dissolve 10 mg of phthalic anhydride in 1 mL of ammonia solution (28), and add water to make 100 mL. To 2 mL of this solution add 95 mL of water, 4 mL of ammonia solution (28), 50 mL of ethanol (95), and 0.1 mL of diluted barium chloride TS (1 in 5); the solution shows a blue-purple color which disappears on the addition of 0.15 mL of 0.1 mol/L sulfuric acid VS.

Phthalic acid \( \text{C}_8\text{H}_4\text{O}_3 \) Colorless or white crystalline powder. Soluble in methanol and in ethanol (95), sparingly soluble in water, and practically insoluble in chloroform.

Melting point: about 200°C (with decomposition).

Content—Not less than 98%. Assay—Weigh accurately about 2.8 g of phthalic acid, add exactly 50 mL of 1 mol/L sodium hydroxide VS and 25 mL of water, and dissolve by heating on a hot plate. After cooling, add 5 drops of phenolphthalein TS, and titrate the excess sodium hydroxide with 0.5 mol/L sulfuric acid VS. Perform a blank determination, and make any necessary correction.

Each mL of 1 mol/L sodium hydroxide VS = 83.07 mg of \( \text{C}_8\text{H}_4\text{O}_3 \)

Phthalic anhydride \( \text{C}_8\text{H}_4\text{O}_3 \) White crystals or crystalline powder.

Melting point \( <2.60; \) 131 – 134°C.
Phthalimide $C_6H_5NO_2$ White to pale brown crystals or powder.

Melting point $<2.60^\circ$: 232 – 237°C

Clarity—1.0 g of phthalimide dissolves in 20 mL of sodium hydroxide TS as a slight turbid solution.

Content: not less than 98.0%. Assay—Weigh accurately about 0.3 g of the substance to be tested, dissolve in 40 mL of $N,N$-dimethylformamide, and titrate $<2.50$ with 0.1 mol/L sodium methoxide VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L sodium methoxide VS $= 14.71$ mg of $C_6H_5NO_2$

Phytonadione $C_{31}H_{46}O_2$ [Same as the namesake monograph]

Picric acid See 2,4,6-trinitrophenol.

Picric acid-ethanol TS See 2,4,6-trinitrophenol-ethanol TS.

Picric acid TS See 2,4,6-trinitrophenol TS.

Picric acid TS, alkaline See 2,4,6-trinitrophenol TS, alkaline.

Pig bile powder for thin-layer chromatography A yellow-gray to yellow-brown powder, having a characteristic odor and a bitter taste. It is practically insoluble in water, in methanol and in ethanol (99.5).

Identification—To 0.1 g of pig bile powder for thin-layer chromatography in a screw-capped test tube, add 1 mL of sodium hydroxide solution (3 in 25), and shake. Heat the tube in an oil bath at 120°C for 4 hours, allow to cool to a lukewarm temperature, add 2 mL of 3 mol/L hydrochloric acid TS and 2 mL of ethyl acetate, shake at 50°C for 30 minutes, and separate ethyl acetate layer as the sample solution. Separately, dissolve 10 mg of hyodeoxycholic acid for thin-layer chromatography in 5 mL of methanol, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography $<2.07>$. Spot 10 μL of the sample solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of acetone, ethyl acetate, water and acetic acid (100) (10:10:3:1) to a distance of about 10 cm, and air-dry the plate. Splay evenly 4-methoxybenzaldehyde-sulfuric acid TS on the plate, heat at 105°C for 10 minutes: spots equivalent to those described below appear.

Polyethylene glycol 1500 for gas chromatography Prepared for gas chromatography.

Polyethylene glycol 6000 for gas chromatography Prepared for gas chromatography.

Polyethylene glycol 2-nitroterephthalate for gas chromatography Prepared for gas chromatography.

Polymethyl acrylate for gas chromatography Prepared for gas chromatography.

Polymethylsiloxane for gas chromatography Prepared for gas chromatography.

Polyethylene glycol hydrogenated castor oil 60 A nonionic surfactant prepared by addition polymerization of ethylene oxide with hydrogenated castor oil. Average molar number of ethylene oxide added is about 60. A white or pale yellow petrolatum-like or waxy substance, having a faint, characteristic odor and a slight bitter taste. Very soluble in ethyl acetate and in chloroform, freely soluble in ethanol (95), slightly soluble in water, and practically insoluble in diethyl ether.

Identification (1) To 0.5 g of polyoxyethylene hydrogenated castor oil 60 add 10 mL of water and 5 mL of ammonium thiocyanate-cobalt (II) nitrate TS, and shake thoroughly. Add 5 mL of chloroform, shake, and allow to stand: a blue color develops in the chloroform layer.

(2) To 0.2 g of polyoxyethylene hydrogenated castor oil 60 add 0.5 g of potassium bisulfate, and heat: an acrolein-stain: a blue color develops in the chloroform layer.

(3) Add 5 mL of chloroform, shake, and allow to stand: a blue color develops in the chloroform layer.

Identification (1) To 0.5 g of polyoxyethylene hydrogenated castor oil 60 add 10 mL of water and 5 mL of ammonium thiocyanate-cobalt (II) nitrate TS, and shake thoroughly. Add 5 mL of chloroform, shake, and allow to stand: a blue color develops in the chloroform layer.

Polyethylene glycol 6000 for gas chromatography Prepared for gas chromatography.

Polyethylene glycol 2-nitroterephthalate for gas chromatography Prepared for gas chromatography.

Polymethyl acrylate for gas chromatography Prepared for gas chromatography.

Polymethylsiloxane for gas chromatography Prepared for gas chromatography.
Viscosity <2.53>: 25.0 – 31.0 mm²/s. Weigh 4.000 g of polyvinyl alcohol I, previously dried, add 95 mL of water, allow to stand for 30 minutes, and heat to dissolve on a water bath under a reflux condenser for 2 hours while stirring. After cooling, add water to make 100.0 g, and mix. Allow to stand still to remove bubbles, and perform the test at 20 ± 0.1°C as directed in Method 1.

pH <2.54>—The pH of a solution of polyvinyl alcohol I (1 in 25) is between 5.0 and 8.0.

Clarity and color of solution—To 1.0 g of polyvinyl alcohol I add 20 mL of water, disperse by well stirring, heat on water bath under a reflux condenser for 2 hours while stirring. After cooling, add water to make 100.0 g, and mix. Allow to stand still to remove bubbles, and perform the test at 20°C for 2 hours, and cool: the solution is colorless and clear.

Saponification value: 98.0 – 99.0 mol%. Weigh accurately about 3.0 g of polyvinyl alcohol I, previously dried, transfer to a glass-stoppered conical flask, add 100 mL of water, and dissolve by heating on a water bath. After cooling, add exactly 25 mL of 0.1 mol/L sodium hydroxide VS, stopper tightly, and allow to stand for 2 hours. Then add exactly 30 mL of 0.05 mol/L sulfuric acid VS, shake well, and titrate <2.50> with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of phenolphthalein TS). Perform a blank determination in the same manner, and make any necessary correction. However, when the volume of 0.1 mol/L sodium hydroxide VS consumed in the test is 25 mL or more, use about 2.0 g of the sample.

\[ S\text{aponification value (mol\%)} = 100 - \frac{60.05 - 0.42 A}{a} \]

where:
- \( A = \frac{0.6005 \times (a - b) f}{\text{amount (g) of the sample}} \)
- \( a \): Volume (mL) of 0.5 mol/L sodium hydroxide VS consumed in the test
- \( b \): Volume (mL) of 0.5 mol/L sodium hydroxide VS consumed in the blank test
- \( f \): Molarity factor of 0.5 mol/L sodium hydroxide VS

Polyvinyl alcohol II—Colorless to white or pale yellow granules or powder. It is odorless, or has a faint odor of acetic acid. It is tasteless. Practically insoluble in ethanol (95) or in diethyl ether. To polyvinyl alcohol II add water, and heat: A clear, viscous solution is obtained. It is hygroscopic.

Viscosity <2.53>: 4.6 – 5.4 mm²/s. Weigh 4.000 g of polyvinyl alcohol II, previously dried, add 95 mL of water, allow to stand for 30 minutes, and dissolve by stirring on a water bath between 60°C and 80°C for 2 hours. After cooling, add water to make 100.0 g, and mix. Allow to stand still to remove bubbles, and perform the test at 20 ± 0.1°C as directed in Method 1.

pH <2.54>—The pH of a solution of polyvinyl alcohol II (1 in 25) is between 5.0 and 8.0.

Clarity and color of solution—To 1.0 g of polyvinyl alcohol II add 20 mL of water, disperse by well stirring, heat on a water bath for 2 hours, and cool: the solution is clear and colorless.

\[ S\text{aponification value (mol\%)} = 100 - \frac{60.05 - 0.42 A}{a} \]

where:
- \( A = \frac{0.6005 \times (a - b) f}{\text{amount (g) of the sample}} \)
- \( a \): Volume (mL) of 0.5 mol/L sodium hydroxide VS consumed in the test
- \( b \): Volume (mL) of 0.5 mol/L sodium hydroxide VS consumed in the blank test
- \( f \): Molarity factor of 0.5 mol/L sodium hydroxide VS

Potassium bicarbonate—See potassium hydrogen carbonate.

Potassium biphthalate—See potassium hydrogen phthalate.

Potassium biphthalate buffer solution, pH 3.5—See potassium hydrogen phthalate buffer solution, pH 3.5.

Potassium biphthalate buffer solution, pH 4.6—See potassium hydrogen phthalate buffer solution, pH 4.6.

Potassium biphthalate buffer solution, pH 5.6—See potassium hydrogen phthalate buffer solution, pH 5.6.

Potassium biphthalate for pH determination—See potassium hydrogen phthalate for pH determination.

Potassium biphthalate (standard reagent)—See potassium hydrogen phthalate (standard reagent).

0.2 mol/L Potassium biphthalate TS for buffer solution—See 0.2 mol/L potassium hydrogen phthalate TS for buffer solution.

Potassium bisulfate—See potassium hydrogen sulfate.

Potassium bromate—KBrO₃ [K 8530, Special class]

Potassium bromide—KBr [K 8506, Special class]

Potassium bromide for infrared spectrophotometry—Crush homocrystals of potassium bromide or potassium bromide, collect a powder passed through a No. 200 (75 μm) sieve, and dry at 120°C for 10 hours or at 500°C for 5 hours. Prepare tablets with this powder, and determine the infrared absorption spectrum <2.25>: any abnormal absorption does not appear.

Potassium carbonate—K₂CO₃ [K 8615, Special class]

Potassium carbonate, anhydrous—See potassium carbonate.
Potassium carbonate-sodium carbonate TS Dissolve 1.7 g of potassium carbonate and 1.3 g of anhydrous sodium carbonate in water to make 100 mL.

Potassium chlorate KClO₃ [K 8207, Special class]

Potassium chloride KCl [K 8121, Special class]

Potassium chloride for conductivity measurement [K 8121, Potassium chloride for conductivity measurement]

Potassium chloride for infrared spectrophotometry Crush homocrystals of potassium chloride or potassium chloride (Special class), collect the powder passed through a No. 200 (75 μm) sieve, and dry at 120°C for 10 hours or at 500°C for 5 hours. Prepare tablets with this powder, and determine the infrared absorption spectrum: any abnormal absorption does not appear.

Potassium chloride-hydrochloric acid buffer solution To 250 mL of a solution of potassium chloride (3 in 20) add 55 mL of 2 mol/L hydrochloric acid TS and water to make 1000 mL.

Potassium chloride TS, acidic Dissolve 250 g of potassium chloride in water to make 1000 mL, and add 8.5 mL of hydrochloric acid.

0.2 mol/L Potassium chloride TS Dissolve 14.9 g of potassium chloride in water to make 1000 mL. Prepare before use.

Potassium chromate K₂CrO₄ [K 8312, Special class]

Potassium chromate TS Dissolve 10 g of potassium chromate in water to make 100 mL.

Potassium cyanide KCN [K 8443, Special class]

Potassium cyanide TS Dissolve 1 g of potassium cyanide in water to make 10 mL. Prepare before use.

Potassium dichromate K₂Cr₂O₇ [K 8517, Special class]

Potassium dichromate (standard reagent) K₂Cr₂O₇ [K 8005, Standard reagent for volumetric analysis]

Potassium dichromate-sulfuric acid TS Dissolve 0.5 g of potassium dichromate in diluted sulfuric acid (1 in 5) to make 100 mL.

Potassium dichromate TS Dissolve 7.5 g of potassium dichromate in water to make 100 mL.

Potassium dihydrogen phosphate KH₂PO₄ [K 9007, Special class]

Potassium dihydrogen phosphate for pH determination KH₂PO₄ [K 9007, for pH determination]

0.1 mol/L Potassium dihydrogen phosphate TS, pH 2.0 Dissolve 13.6 g of potassium dihydrogen phosphate in water to make 1000 mL. Adjust the pH to 2.0 with phosphoric acid.

0.25 mol/L Potassium dihydrogen phosphate TS, pH 3.5 Dissolve 34 g of potassium dihydrogen phosphate in 900 mL of water, adjust the pH to 3.5 with phosphoric acid, and add water to make 1000 mL.

0.05 mol/L Potassium dihydrogen phosphate, pH 3.0 Adjust the pH of 0.05 mol/L potassium dihydrogen phosphate TS to 3.0 with phosphoric acid.

0.05 mol/L Potassium dihydrogen phosphate TS, pH 4.7 Dissolve 6.80 g of potassium dihydrogen phosphate in 900 mL of water, adjust the pH to exactly 4.7 with dilute sodium hydrochloride TS, and add water to make 1000 mL.

0.01 mol/L Potassium dihydrogen phosphate TS, pH 4.0 Dissolve 1.4 g of potassium dihydrogen phosphate in 1000 mL of water, and adjust the pH to 4.0 with phosphoric acid.

0.02 mol/L Potassium dihydrogen phosphate TS Dissolve 2.72 g of potassium dihydrogen phosphate in water to make 1000 mL.

0.05 mol/L Potassium dihydrogen phosphate TS Dissolve 6.80 g of potassium dihydrogen phosphate in water to make 1000 mL.

0.33 mol/L Potassium dihydrogen phosphate TS Dissolve 4.491 g of potassium dihydrogen phosphate in water to make 1000 mL.

0.1 mol/L Potassium dihydrogen phosphate TS Dissolve 13.61 g of potassium dihydrogen phosphate in water to make 1000 mL.

0.2 mol/L Potassium dihydrogen phosphate TS Dissolve 27.22 g of potassium dihydrogen phosphate in water to make 1000 mL.

0.2 mol/L Potassium dihydrogen phosphate TS for buffer solution Dissolve 27.218 g of potassium dihydrogen phosphate for pH determination in water to make 1000 mL.

Potassium disulfate K₂S₂O₇ [K 8783, Potassium Dioxide]

Potassium ferricyanide TS See potassium hexacyanoferrate (II) TS.

Potassium ferricyanide See potassium hexacyanoferrate (III) TS.

Potassium ferricyanide TS, alkaline See potassium hexacyanoferrate (III) TS, alkaline.

Potassium ferrocyanide TS See potassium hexacyanoferrate (I) trihydrate.

Potassium ferrocyanide TS See potassium hexacyanoferrate (II) TS.

Potassium guaiacolsulfonate C₇H₇KO₅S [Same as the namesake monograph]

Potassium hexacyanoferrate (II) trihydrate K₃Fe(CN)₆·3H₂O [K 8802, Special class]

Potassium hexacyanoferrate (II) TS Dissolve 1 g of potassium hexacyanoferrate (II) trihydrate in water to make 10 mL (½ mol/L). Prepare before use.

Potassium hexacyanoferrate (III) K₃Fe(CN)₆ [K 8801, Special class]

Potassium hexacyanoferrate (III) TS Dissolve 1 g of potassium hexacyanoferrate (III) in water to make 10 mL (½ mol/L). Prepare before use.

Potassium hexacyanoferrate (III) TS, alkaline Dissolve 1.65 g of potassium hexacyanoferrate (III) and 10.6 g of anhydrous sodium carbonate in water to make 100 mL. Preserve in light-resistant containers.
Potassium hexahydroxoantimonate (V)  \( \text{K}_2\text{H}_2\text{Sb}_2\text{O}_7 \)
White granules or crystalline powder.

*Identification*—To 1 g add 100 mL of water, and dissolve by warming. To 20 mL of this solution add 0.2 mL of sodium chloride TS: white precipitates appear. Rubbing the inside wall of the vessel with a glass rod accelerates the forming of the precipitates.

Potassium hexahydroxoantimonate (V) TS  To 2 g of potassium hexahydroxoantimonate (V) add 100 mL of water. Boil the solution for about 5 minutes, cool quickly, add 10 mL of a solution of potassium hydroxide (3 in 20), allow to stand for 1 day, and filter.

Potassium hydrogen carbonate  \( \text{KHCO}_3 \)  [K 8621, Special class]

Potassium hydrogen phthalate  \( \text{C}_6\text{H}_4\text{(COOK)}\text{(COOH)} \)  [K 8809, Special class]

Potassium hydrogen phthalate buffer solution, \( \text{pH} \) 3.5  Dilute 50 mL of 0.2 mol/L potassium hydrogen phthalate TS for buffer solution and 7.97 mL of 0.2 mol/L hydrochloric acid VS with water to make 200 mL.

Potassium hydrogen phthalate buffer solution, \( \text{pH} \) 4.6  Dilute 50 mL of 0.2 mol/L potassium hydrogen phthalate TS for buffer solution and 12.0 mL of 0.2 mol/L sodium hydroxide VS with water to make 200 mL.

0.3 mol/L Potassium hydrogen phthalate buffer solution, \( \text{pH} \) 4.6  Dissolve 61.26 g of potassium hydrogen phthalate in about 800 mL of water, adjust the \( \text{pH} \) to 4.6 with sodium hydroxide TS, and add water to make 1000 mL.

Potassium hydrogen phthalate buffer solution, \( \text{pH} \) 5.6  Dilute 50 mL of 0.2 mol/L potassium hydrogen phthalate TS for buffer solution and 39.7 mL of 0.2 mol/L sodium hydroxide VS with water to make 200 mL.

Potassium hydrogen phthalate for \( \text{pH} \) determination  \( \text{C}_6\text{H}_4\text{(COOK)}\text{(COOH)} \)  [K 8809, For \( \text{pH} \) determination]

Potassium hydrogen phthalate (standard reagent)  \( \text{C}_6\text{H}_4\text{(COOK)}\text{(COOH)} \)  [K 8805, Standard reagent for volumetric analysis]

0.2 mol/L Potassium hydrogen phthalate TS for buffer solution  Dissolve 40.843 g of potassium hydrogen phthalate for \( \text{pH} \) determination in water to make 1000 mL.

Potassium hydrogen sulfate  \( \text{KHSO}_4 \)  [K 8972, Special class]

Potassium hydroxide  \( \text{KOH} \)  [K 8574, Special class]

Potassium hydroxide-ethanol TS  Dissolve 10 g of potassium hydroxide in ethanol (95) to make 100 mL. Prepare before use.

0.1 mol/L Potassium hydroxide-ethanol TS  To 1 mL of dilute potassium hydroxide-ethanol TS add ethanol (95) to make 5 mL. Prepare before use.

Potassium hydroxide-ethanol TS, dilute  Dissolve 35 g of potassium hydroxide in 20 mL of water, and add ethanol (95) to make 1000 mL (0.5 mol/L). Preserve in tightly stoppered bottles.

Potassium hydroxide TS  Dissolve 6.5 g of potassium hydroxide in water to make 100 mL (1 mol/L). Preserve in polyethylene bottles.

0.02 mol/L Potassium hydroxide TS  Dilute 2 mL of potassium hydroxide TS with water to make 100 mL. Prepare before use.

0.05 mol/L Potassium hydroxide TS  Dilute 5 mL of potassium hydroxide TS with water to make 100 mL. Prepare before use.

8 mol/L Potassium hydroxide TS  Dissolve 52 g of potassium hydroxide in water to make 100 mL. Preserve in polyethylene bottles.

Potassium iodate  \( \text{KIO}_3 \)  [K 8922, Special class]

Potassium iodate (standard reagent)  \( \text{KIO}_3 \)  [K 8005, Standard reagent for volumetric analysis]

Potassium iodide  \( \text{KI} \)  [K 8913, Special class]

Potassium iodide for assay  [Same as the monograph Potassium Iodide]

Potassium iodide-starch TS  Dissolve 0.5 g of potassium iodide in 100 mL of freshly prepared starch TS. Prepare before use.

Potassium iodide TS  Dissolve 16.5 g of potassium iodide in water to make 100 mL. Preserve in light-resistant containers. Prepare before use (1 mol/L).

Potassium iodide TS, concentrated  Dissolve 30 g of potassium iodide in 70 mL of water. Prepare before use.

Storage—Preserve in light-resistant containers.

Potassium iodide TS, saturated  Saturate 20 g of potassium iodide in 10 mL of freshly boiled and cooled water. Prepare before use.

Potassium iodide-zinc sulfate TS  Dissolve 5 g of potassium iodide, 10 g of zinc sulfate, and 50 g of sodium chloride in water to make 200 mL.

Potassium methanesulfonate  \( \text{CH}_3\text{SO}_3\text{K} \)  White crystals or crystalline powder.

Purity  Clarity and color of solution—Dissolve 1.0 g of potassium methanesulfonate in 20 mL of water: the solution is transparent and colorless.

Content: not less than 98.0%. Assay—Dissolve about 0.1 g of potassium methanesulfonate, accurately weighed, in 10 mL of acetic acid (100), add 20 mL of acetic anhydride, and titrate \( <2.50\text{mL} \) with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 13.42 mg of \( \text{CH}_3\text{SO}_3\text{K} \)

Potassium naphthoquinone sulfonate  See potassium 1,2-naphthoquinone-4-sulfonate.

Potassium 1,2-naphthoquinone-4-sulfonate  \( \text{C}_9\text{H}_6\text{O}_4\text{SO}_3\text{K} \)  [K 8696, \( \beta \)-Naphthoquinone-4-sulfonic acid potassium salt, Special class]

Potassium 1,2-naphthoquinone-4-sulfonate TS  Dissolve 0.5 g of potassium 1,2-naphthoquinone-4-sulfonate in water to make 100 mL. Prepare before use.

Potassium nitrate  \( \text{KNO}_3 \)  [K 8548, Special class]
Potassium nitrite  KNO₂ - A white to pale yellow crystalline powder. It is deliquescent.

Identification—(1) Dissolve 1 g of potassium nitrite in 20 mL of water, and use this as the sample solution. To 5 mL of the sample solution add 1 mL of sulfuric acid: a yellowish brown gas is evolved.

(2) The sample solution obtained in (1) responds to the Qualitative Tests <1.00> (1) for potassium salt. Preserve in a light-resistant tight container.

Potassium periodate  KIO₄ - [K 8249, Special class]

Potassium periodate TS - To 2.8 g of potassium periodate add 200 mL of water, dissolve by adding dropwise 20 mL of sulfuric acid under shaking, cool, and add water to make 1000 mL.

Potassium permanganate  KMnO₄ - [K 8247, Special class]

Potassium permanganate TS - Dissolve 3.3 g of potassium permanganate in water to make 1000 mL (0.02 mol/L).

Potassium permanganate TS, acidic - To 100 mL of potassium permanganate TS add 0.3 mL of sulfuric acid.

Potassium persulfate  K₂S₂O₈ - [K 8253, Special class]

Potassium pyroantimonate - See potassium hexahydroxoantimonate (V).

Potassium pyroantimonate TS - See potassium hexahydroxoantimonate (V) TS.

Potassium pyrophosphate  K₂P₂O₇ - White, crystalline powder, very soluble in water.

Melting point <2.60>: 1109°C

Potassium pyrosulfate - See potassium disulfate.

Potassium sodium tartrate - See potassium sodium tartarate tetrahydrate.

Potassium sodium tartrate tetrahydrate  KNaC₄H₄O₆·4H₂O - [K 8536, (±)-Potassium sodium tartrate tetrahydrate, Special class]

Potassium sulfate  K₂SO₄ - [K 8962, Special class]

Potassium sulfate TS - Dissolve 1 g of potassium sulfate in water to make 100 mL.

Potassium tartrate  2C₄H₆K₂O₆·H₂O - [K 8535, (±)-Potassium Tartrate-Water (2/1), Special class]

Potassium tellurite  K₂TeO₃ - White powder or small masses obtained by melting an equimolar mixture of tellurium dioxide and potassium carbonate in a stream of carbon dioxide. Soluble in water.

Content: not less than 90.0%. Assay—Dissolve about 1.0 g of potassium tellurite, accurately weighed, in 100 mL of water, add 5 mL of diluted acetic acid (31) (1 in 3), and boil. After cooling, filter by suction through a crucible glass filter (14G), previously dried at 105 ± 2°C for 1 hour to constant mass (b g). Wash the filtrate with water, dry the glass filter at 110°C for 3 hours, and measure the mass a (g).

\[
\text{Content (\%) of potassium tellurite (K}_2\text{TeO}_3) = \frac{(a - b) \times 1.5902}{S} \times 100
\]

S: Mass (g) of potassium tellurite taken.

Potassium tetroxalate for pH determination - See potassium trihydrogen dioxalate dihydrate for pH determination.

Potassium thiocyanate  KSCN - [K 9001, Special class]

Potassium thiocyanate TS - Dissolve 1 g of potassium thiocyanate in water to make 10 mL.

Potassium trihydrogen dioxalate dihydrate for pH determination  KH₃(C₂O₄)₂·2H₂O - [K 8474]

Potato extract - Prepared for microbial test.

Potato starch - Same as the namesake monograph.

Potato starch TS - Prepare as directed under starch TS with 1 g of potato starch.

Potato starch TS for amylolytic activity test - Dry about 1 g of potato starch, accurately weighed, at 105°C for 2 hours, and measure the loss. Weigh accurately an amount of potato starch, equivalent to 1.000 g on the dried basis, place into a conical flask, add 20 mL of water, and make it pasty by gradually adding 5 mL of a solution of sodium hydroxide (2 in 25) while shaking well. Heat in a water bath for 3 minutes while shaking, add 25 mL of water, and cool. Neutralize exactly with 2 mol/L hydrochloric acid TS, add 10 mL of 1 mol/L acetic acid-sodium acetate buffer solution, pH 5.0, and add water to make exactly 100 mL. Prepare before use.

Powdered tragacanth - Same as the namesake monograph.

(±)-Praeruptorin A for thin-layer chromatography  C₁₂H₁₇O₁₇ - White crystals or crystalline powder. Soluble in methanol, sparingly slightly soluble in ethanol (99.5), and practically insoluble in water.

Identification—Determine the absorption spectrum of a solution of (±)-praeruptorin A for thin-layer chromatography in methanol (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits a maximum between 320 nm and 324 nm.

Melting point <2.60>: 152 – 156°C

Pravastatin sodium  C₂₅H₃₅NaO₇ - [Same as the namesake monograph]

Prazepam for assay  C₁₉H₁₇ClN₂O - [Same as the monograph Prazepam. When dried, it contains not less than 99.0% of C₁₉H₁₇ClN₂O.]

Prednisolone  C₂₁H₂₈O₅ - [Same as the namesake mono-
graph]

Prednisolone acetate $C_{23}H_{30}O_6$ [Same as the namesake monograph]

Prednisone $C_{21}H_{29}O_7$. White, crystalline powder. Slightly soluble in methanol, in ethanol (95) and in chloroform, and very slightly soluble in water.

Optical rotation $\angle 2.49^\circ$ [g] $\oplus$: +167 – +175° (after drying, 0.1 g, 1,4-dioxane, 10 mL, 100 mm). Loss on drying $\angle 2.41^\circ$: not more than 1.0% (1 g, 105°C, 3 hours).

Content: 96.0 – 104.0%. Assay—Weigh accurately about 20 mg of prednisone, and dissolve in methanol to make exactly 100 mL. Pipet 5 mL of this solution, dilute with methanol to make exactly 100 mL. Perform the test with this solution as directed under Ultraviolet-visible Spectrophotometry $\angle 2.24^\circ$, and read the absorbance $A$ at the wavelength of maximum absorption at about 238 nm.

Amount (mg) of $C_{21}H_{29}O_7$: $A = \frac{440}{280} \times 20,000$

Probenecid $C_{17}H_{18}O_5\text{N}_2$ [Same as the namesake monograph]

Procainamide hydrochloride $C_{13}H_{21}N_3O\cdot HCl$ [Same as the namesake monograph]

Procainamide hydrochloride for assay $C_{13}H_{21}N_3O\cdot HCl$ [Same as the namesake monograph Procainamide Hydrochloride. When dried, it contains not less than 99.0% of procainamide hydrochloride ($C_{13}H_{21}N_3O\cdot HCl$).]

Propafenone hydrochloride for assay $C_{16}H_{21}N_2O_3\cdot HCl$ [Same as the namesake monograph Procaterol Hydrochloride. When dried, it contains not less than 99.5% of propafenone hydrochloride ($C_{16}H_{21}N_2O_3\cdot HCl$).] [Same as the namesake monograph Propranolol Hydrochloride. When dried, it contains not less than 99.0% of propafenone hydrochloride ($C_{16}H_{21}N_2O_3\cdot HCl$).]

Propylbenzoate $C_6H_5COOC_3H_7$. Clear, colorless liquid, having a characteristic odor. Miscible with water, with ethanol (95) and with diethyl ether. Boiling point: about 82°C.

Refractive index $\angle 2.50^\circ$ $n_2^D$: 1.376 – 1.378

Specific gravity $\angle 2.50^\circ$ : $d_2^D$: 0.785 – 0.788

Purity (1) Ultraviolet absorbing substances—Perform the test with 2-propanol for liquid chromatography as directed under Ultraviolet-visible Spectrophotometry $\angle 2.24^\circ$, using water as the blank: the absorbance at 230 nm is not more than 0.2; at 250 nm, not more than 0.03; and between 280 nm and 400 nm, not more than 0.01.

(2) Peroxide—Mix 100 mL of water and 25 mL of dilute sulfuric acid, and add 25 mL of a solution of potassium iodide (1 in 10). Add this solution to 20 g of 2-propanol for liquid chromatography. Stopper tightly, shake, allow to stand for 15 minute in a dark place, and titrate $\angle 2.50^\circ$ with 0.01 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS). Perform a blank determination in the same manner, and make any necessary correction (not more than 0.0005%).

Propranolol, iso See 2-propanol.

Propranolol hydrochloride for assay $C_{16}H_{22}N_2O_3\cdot HCl$ [Same as the namesake monograph Propranolol Hydrochloride. When dried, it contains not less than 99.5% of propranolol hydrochloride ($C_{16}H_{22}N_2O_3\cdot HCl$).]

Propanol, iso See Water determination.

Propanol, $CH_3CH_2CH_2OH$ [K 8838, Special class]

Propylene carbonate $C_4H_6O_3$. Colorless liquid. Refractive index $\angle 2.57^\circ$: 1.397 – 1.400

Distilling range $\angle 2.57^\circ$: 54 – 54°C, not less than 95 vol%.

Propylamine, iso $C_9H_{19}\text{CNH}_2$. Colorless liquid, having a characteristic, amine-like odor. Miscible with water, with ethanol (95) and with diethyl ether.

Refractive index $\angle 2.50^\circ$ $n_2^D$: 1.374 – 1.376

Specific gravity $\angle 2.50^\circ$ : $d_2^D$: 0.685 – 0.690

Distilling range $\angle 2.57^\circ$: 31 – 33°C, not less than 95 vol%.

Propylbenzoate $C_6H_5COOC_3H_7$. Clear, colorless liquid, having a characteristic odor.

Refractive index $\angle 2.50^\circ$ $n_2^D$: 1.498 – 1.503

Specific gravity $\angle 2.50^\circ$ : $d_2^D$: 1.022 – 1.027

Propylene carbonate $C_4H_6O_3$. Colorless liquid.

Boiling point $\angle 2.57^\circ$: 240 – 242°C

Water $\angle 2.48^\circ$: less than 0.1%.

Propylene carbonate for water determination See Water Determination $\angle 2.48^\circ$.

Propylene glycol $CH_2CH(OH)CH_2OH$ [K 8837, Special class]

Propylene glycol cefazolin $C_{11}H_{17}O_5\cdot S_2\cdot C_2H_3O_2$ [Same as the namesake monograph]

Propyler, iso $(CH_3)_2CHOCH(CH_3)_2$. Clear, colorless
liquid, having a characteristic odor. Not miscible with water. 

Refractive index \(< 2.45 > n_{20}^0: 1.368 – 1.369

Specific gravity \(< 2.56 > d_{20}^0: 0.723 – 0.725

Propyl parahydroxybenzoate

\( \text{HOCH}_2\text{H}_2\text{COOCCH}_2\text{CH}_3 \) [Same as the namesake monograph]

Propylthiouracil for assay \( \text{C}_9\text{H}_13\text{N}_2\text{O}_5 \) [Same as the monograph Propylthiouracil. When dried, it contains not less than 99.0% of propylthiouracil (\( \text{C}_9\text{H}_13\text{N}_2\text{O}_5 \)).]

Prostaglandin A\(_1\) \( \text{C}_{20}\text{H}_{19}\text{O}_4 \) White crystals or crystalline powder. Very soluble in ethanol (95) and in ethyl acetate, and very slightly soluble in water.

Purity Related substances—Dissolve 5 mg of prostaglandin A\(_1\) in 10 mL of ethanol (95), and use this solution as the sample solution. Pipet 3 mL of the sample solution, add ethanol (95) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 \( \mu \)L of each of the sample solution and standard solution as directed in the Assay (1) under Kakkonto Extract: the total area of the peaks other than pseudoephedrine and the solvent is not larger than the peak area of prostaglandin A\(_1\) from the standard solution. Perform the test with this solution as directed under Ultraviolet-spectrophotometry.

Operating conditions

Detector, column, column temperature, mobile phase, flow rate, and selection of columns: Proceed the operating conditions in the Assay of Alprostadil Alfadex.

Detection sensitivity: Adjust the detection sensitivity so that the peak height of prostaglandin A\(_1\) obtained from 10 \( \mu \)L of the standard solution is 5 to 10\% of the full scale.

Time span of measurement: About twice as long as the retention time of prostaglandin A\(_1\) beginning after the solvent peak.

Protein digestive enzyme TS A solution of lysyl endopeptidase in 0.05 mol/L tris buffer solution, pH 8.6 (1 in 5000).

Pseudoephedrine hydrochloride \( \text{C}_{10}\text{H}_{12}\text{NO}.\text{HCl} \) White, crystals or crystalline powder. Freely soluble in water, in methanol and in acetic acid (100), soluble in ethanol (99.5), and practically insoluble in acetic anhydride. Melting point: 182 – 186\°C

Purity Related substances—Dissolve 1 mg in 10 mL of diluted methanol (1 in 2), and use this solution as the sample solution. Perform the test with 10 \( \mu \)L of the sample solution for twice as long as the retention time of ephedrine as directed in the Assay (1) under Kakkonto Extract: the total area of the peaks other than pseudoephedrine and the solvent is not larger than 1/10 times the total area of the peaks other than the solvent.

Puerarin for thin-layer chromatography \( \text{C}_{21}\text{H}_{20}\text{O}_8 \) White crystalline powder. Freely soluble in methanol, and practically insoluble in diethyl ether. Melting point: about 188\°C (with decomposition).

Purity Related substances—Dissolve 1.0 mg of puerarin for thin-layer chromatography in exactly 1 mL of methanol. Perform the test with 2 \( \mu \)L of this solution as directed in the Identification under Pueraria Root: any spot other than the principal spot at the \( R_f \) value of about 0.4 does not appear.

Pullulanase An enzyme obtained from Klebsiella pneumoniae. White crystals. It contains not less than 30 units per mg. One unit is an enzymatic activity to produce 1 \( \mu \)mol of maltotriose from pullulan per minute at pH 5.0 and 30\°C.

Pullulanase TS A solution of pullulanase containing 10 units per mL.

Purified hydrochloric acid See hydrochloric acid, purified.

Purified methanol See methanol, purified.

Purified sulfuric acid See sulfuric acid, purified.

Purified water [Use the water prescribed by the monographs of Purified Water or Purified Water in Containers. It is not necessary to check the conformity to all the specification items of the monograph, if it is confirmed that the water to be used is suitable for the purpose of the relevant test.]

Pyrazole \( \text{C}_7\text{H}_8\text{N}_2\) White to pale yellow crystals or crystalline powder.

Melting point \(< 2.60\°: 67 – 71\°C

Pyridine \( \text{C}_3\text{H}_7\text{N} \) [K 8777, Special class]

Pyridine-acetic acid TS Dilute 20 mL of pyridine with sufficient diluted acetic acid (100) (1 in 25) to make 100 mL. Prepare before use.

Pyridine, dehydrated \( \text{C}_3\text{H}_7\text{N} \) To 100 mL of pyridine add 10 g of sodium hydroxide, and allow to stand for 24 hours. Decant the supernatant liquid, and distill.

Pyridine for Karl Fischer method See Water Determination \(< 2.40\°.

0.2 mol/L Pyridine-formic acid buffer solution, pH 3.0

To 15.82 g of pyridine add 900 mL of water, shake well, adjust the pH to 3.0 with diluted formic acid (1 in 2), and add water to make 1000 mL.

Pyridine-pyrazoline TS Dissolve, with thorough shaking, 0.1 g of 3-methyl-1-phenyl-5-pyrazoline in 100 mL of water by heating between 65\°C and 70\°C, and cool below 30\°C. Mix this solution with a solution prepared by dissolving 0.02 g of bis-(1-phenyl-3-methyl-5-pyrazoline) in 20 mL of pyridine. Prepare before use.

Pyridoxine hydrochloride \( \text{C}_{13}\text{H}_{15}\text{NO}_3.\text{HCl} \) [Same as the namesake monograph]

\( \text{1-(2-Pyridylazo)-2-naphthol} \) Orange-yellow or orange-red powder.

Absorbance—Dissolve 25 mg of 1-(2-pyridylazo)-2-naphthol in methanol to make exactly 100 mL. Pipet 2.0 mL of this solution, and add methanol to make exactly 50 mL. Perform the test with this sample solution as directed under Ultraviolet-visible Spectrophotometry \(< 2.24\°, using methanol as the blank: absorbance at the wavelength of 470 nm is not less than 0.55.

Melting point \(< 2.60\°: 137 – 140\°C

Purity Clarity and color of solution—Dissolve 25 mg of 1-(2-pyridylazo)-2-naphthol in 100 mL of methanol: the solution is clear and orange-yellow.

Residue on ignition \(< 2.40\°: not more than 1.0%.

Sensitivity—On adding 50 mL of water, 30 mL of methanol and 10 mL of acetic acid-sodium acetate buffer solution, pH 5.5, to 0.2 mL of a solution of 1-(2-pyridylazo)-2-
naphthol in methanol (1 in 4000), the solution is yellow in color. Add 1 drop of a solution of copper (II) chloride dihydrate (1 in 600) to this solution: the solution is red-purple in color. Add a subsequent 1 drop of diluted 0.1 mol/L disodium dihydrogen ethylenediamine tetracacetate TS (1 in 10): the color of the solution changes to yellow again.

1-(4-Pyridyl)pyridinium chloride hydrochloride

C_{19}H_{26}N_8O_6.HCl White to yellowish white, crystalline powder. Very soluble in water, very slightly soluble in ethanol (95), and practically insoluble in diethyl ether.

Melting point <2.60>: 154 – 156°C

Pyrogallol C_{6}H_{4}(OH)_3 [K 8780, Special class]

1-Pyroglutamylglycyl-L-arginine-p-nitroaniline hydrochloride

C_{19}H_{26}N_8O_6.HCl White to light powder. Freely soluble in water, in methanol and in acetic acid (100).

Absorbance <2.24> E_{1cm}^1% (316 nm): 242 – 268 (2 mg, water, 100 mL).

Optical rotation <2.49> [α]_D: –51 – –56° [0.1 g, diluted acetic acid (100) (1 in 2), 10 mL, 100 mm].

Purity Related substances—Dissolve 0.05 g of 1-pyroglutamylglycyl-L-arginine-p-nitroaniline hydrochloride in 10 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 50 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.06>. Spot 20 μL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water, and silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

1-Pyroglutamylglycyl-L-arginine-p-nitroaniline hydrochloride TS

Dissolve 25 mg of 1-pyroglutamylglycyl-L-arginine-p-nitroaniline hydrochloride and 0.04 g of D-Mannitol in 2 to 3 mL of water, lyophilize, and add 16.7 mL of water to dissolve. To 1 volume of this solution add 9 volumes of water before use.

Pyrole C_{6}H_{5}N Clear, colorless liquid, having a characteristic odor. Soluble in ethanol (95) and in diethyl ether, and practically insoluble in water.

Specific gravity <2.56> d_{20}^3: 0.965 – 0.975

Pyrophosphate buffer solution, pH 9.0

Dissolve 3.3 g of potassium pyrophosphate, 15 mg of dithiothreitol and 40 mg of disodium dihydrogen ethylenediamine tetracacetate dihydrate in 70 mL of water, adjust the pH with a solution of citric acid monohydrate (21 in 100) to exactly 9.0, and add water to make 100 mL.

0.05 mol/L Pyrophosphate buffer solution, pH 9.0

Dissolve 0.83 g of potassium pyrophosphate in 40 mL of water, adjust the pH with 1 mol/L hydrochloric acid VS to 9.0, and add water to make 50 mL. Adjust the temperature to 22 ± 2°C before use.

Quinapril hydrochloride for assay

C_{25}H_{30}N_2O_5.HCl [Same as the monograph Quinapril Hydrochloride. When performing the purity test (2) of Quinapril Hydrochloride, the area of the peaks, having the relative retention time of about

0.5 and about 2.0 to quinapril obtained from the sample solution, is not larger than the peak area of quinapril from the standard solution, the area of peak other than quinapril and above mentioned peak from the sample solution is not larger than 2/5 times the peak area of quinapril from the standard solution, and the total area of the peaks other than quinapril from the sample solution is not larger than 2 times the peak area of quinapril from the standard solution.]

Quinhydrone C_{6}H_{4}(OH)_2.C_{6}H_10O_2 Green crystals or crystalline powder.

Melting point <2.60>: 169 – 172°C

Quinidine sulfate See quinidine sulfate hydrate.

Quinidine sulfate hydrate (C_{20}H_{24}N_2O_2)_{2}.H_2SO_4.2H_2O [Same as the monograph monograph]

Quinine sulfate See quinine sulfate hydrate.

Quinine sulfate hydrate (C_{20}H_{24}N_2O_2)_{2}.H_2SO_4.2H_2O [Same as the monograph monograph]

Quinoline C_{6}H_{5}N [K 8279, Special class]

Quinoline TS Mix 50 mL of quinoline with 300 mL of diluted hydrochloric acid (1 in 6), previously heated, cool, and filter if necessary.

8-Quinolinol C_{6}H_{5}NO [K 8775, Special class]

Raney nickel catalyst Grayish black powder. An alloy containing 40 to 50% of nickel and 50 to 60% of aluminum.

Ranitidinediamine (C_{10}H_{18}N_2OS)_{2}.C_{4}H_{4}O_4 White to pale yellow crystalline powder.

Identification—Determine the infrared absorption spectrum of ranitidinediamine as directed in the paste method under Infrared Spectrophotometry <2.25>; it exhibits absorption at the wave numbers of about 2780 cm⁻¹, 1637 cm⁻¹, 1015 cm⁻¹ and 788 cm⁻¹.

Content: not less than 95%. Assay—Weigh accurately about 0.1 g of ranitidinediamine, dissolve in 50 mL of acetic acid (100), and titrate with 0.1 mol/L perchloric acid VS until the color of the solution changes from purple to green through blue (indicator: crystal violet TS). Perform the blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 13.62 mg of (C_{9}H_{17}N_2O_4).[C_{9}H_{15}ClN_2O_4].

Rebamipide for assay C_{19}H_{15}ClN_2O_4 [Same as the monograph Rebamipide. When dried, it contains not less than 99.5% of rebamipide (C_{19}H_{15}ClN_2O_4).]

Reduced iron See iron powder.

Reference anti-interleukin-2 antibody for teceleukin Monoclonal antibody obtained from a fusion cell strain from mouse spleen cells sensitized to teceleukin and mouse melanoma cells, or alternately, rabbit antiserum towards human interleukin-2, that is purified using affinity chromatography. When determining the neutralizing activity, taking 1 neutralizing unit as the titer that neutralizes one unit of activity of teceleukin, contains at least 2000 neutralizing units per 1 mL.

Reinecke salt See reinecke salt monohydrate.

Reinecke salt monohydrate NH_{4}[Cr(NH_3)_2(SCN)_4].H_2O
Dark red crystals or crystalline powder.

Identification—Determine the infrared absorption spectrum of Reineke salt monohydrate as directed in the potassium bromide disk method as directed under Spectrophotometry \( \leq 2.25\% \): it exhibits absorption at the wave numbers of about 3310 cm\(^{-1} \), 2130 cm\(^{-1} \), 1633 cm\(^{-1} \), 1400 cm\(^{-1} \), 1261 cm\(^{-1} \) and 711 cm\(^{-1} \).

Reineke salt TS

To 20 mL of water add 0.5 g of Reineke salt monohydrate, shake frequently for 1 hour, then filter. Use within 48 hours.

Resazurin C\(_6\)H\(_5\)NNaO\(_4\) Brownish purple powder. It dissolves in water and the solution is purple in color.

Residue on ignition \( < 2.44\% \): not less than 28.5\% (1 g).

Resibufogenin for assay C\(_{25}\)H\(_{32}\)O\(_4\)xH\(_2\)O Odorless white crystalline powder.

Absorbance \( < 2.24\% \): \( E_{1\%}^{1\text{cm}} \) (300 nm): 131 – 145 (0.01 g, methanol, 250 mL), dried in a desiccator (silica gel) for 24 hours.

Purity Related substances—Weigh accurately 40 mg of resibufogenin for assay and proceed as directed in the Purity under bufalin for assay.

Content: not less than 98.0\%. Assay—Weigh accurately about 10 mg of resibufogenin for assay, previously dried in a desiccator (silica gel) for 24 hours, add methanol to make exactly 10 mL, and use this solution as the sample solution. Perform the test with 20 \( \mu \)L of this solution as directed under Liquid Chromatography \( < 2.01\% \) according to the following conditions. Measure each peak area by the automatic integration method, and calculate the amount of resibufogenin by the area percentage method.

Operating conditions

Detector: Ultraviolet absorption photometer (wavelength: 300 nm).

Column: A stainless steel column about 4 to 6 mm in inside diameter and 15 to 30 cm in length, packed with octadecysilanolized silica gel for liquid chromatography (5 to 10 \( \mu \)m in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of water and acetonitrile (1:1). Selection of column: Dissolve 0.01 g each of bufalin for assay, cinobufagin for assay and resibufogenin for assay in methanol to make 200 mL. Perform the test with 20 \( \mu \)L of this solution according to the above operating conditions, and calculate the resolution. Use a column giving elution of this solution according to the above operating conditions, and calculate the amount of resibufogenin from 20 \( \mu \)L of the standard solution (1) is about 20\% of the full scale.

Time span of measurement: About twice as long as the retention time of resibufogenin beginning after the peak of solvent.

Resibufogenin for component determination See resibufogenin for assay.

Resibufogenin for thin-layer chromatography C\(_{24}\)H\(_{32}\)O\(_4\)xH\(_2\)O White crystalline powder having no odor. It is freely soluble in acetone and in methanol.

Purity Related substances—Dissolve 5.0 mg of the substance to be tested in exactly 5 mL of acetone. Perform the test with 5 \( \mu \)L of this solution as directed in the Identification under Toad Venom: no other spots than the principal spot of around \( Rf \) 0.4 appear.

Resolving gel for celmoleukin Prepare the resolving gel in tris buffer solution, \( p\)H 8.8 using ammonium persulfate and \( N,N,N',N'\)-tetramethylethylenediamine so the concentrations of acrylamide and sodium lauryl sulfate are 13.5\% and 0.1\%, respectively.

Resorcin See resorcinol.

Resorcinol C\(_6\)H\(_4\)(OH)\(_2\) [K 9032, Special class]

Resorcinol sulfuric acid TS Dissolve 0.1 g of resorcinol in 10 mL of diluted sulfuric acid (1 in 10).

Resorcin TS Dissolve 0.1 g of resorcinol in 10 mL of hydrochloric acid. Prepare before use.

Resorcin sulfuric acid TS See resorcinol sulfuric acid TS.

Resorcin TS See resorcinol TS.

\( \Lambda \)-Rhamnose monohydrate C\(_{12}\)H\(_{22}\)O\(_4\) White crystalline powder having sweet taste. Freely soluble in water, and sparingly soluble in ethanol (95).

Optical rotation \( < 2.49\% \): \( [\alpha]_{D}^{24} \): + 7.8 – + 8.3° (1 g, 20 mL of water, 2 drops of ammonium TS, 100 mm).

Melting point \( < 2.60\% \): 87 – 91°C

Purity Related substances—Dissolve 1.0 mg of \( \Lambda \)-rhamnose monohydrate in 1 mL of water, and add methanol to make exactly 10 mL. Proceed with 20 \( \mu \)L of this solution as directed in the Identification (2) under Acacia: any spot other than the principal spot at the \( Rf \) value of about 0.5 does not appear.

Rhine for thin-layer chromatography C\(_9\)H\(_8\)O\(_2\) A yellow powder. Very slightly soluble in acetone, and practically insoluble in water, in methanol, and in ethanol (99.5). Melting point: about 320°C (with decomposition).

Identification—Determine the absorption spectrum of a solution in methanol (3 in 500,000) as directed under Ultraviolet-visible Spectrophotometry \( < 2.24\% \): it exhibits maxima between 228 nm and 232 nm, between 255 nm and 259 nm, and between 429 nm and 433 nm.

Purity Related substances—Dissolve 1.0 mg in 10 mL of acetone, and perform the test with 2 \( \mu \)L of this solution as directed in the Identification (1) under Daikokanzoto Extract: no spot other than the principal spot (\( RF \) value is about 0.3) appears.

Rhnycophylline for assay C\(_{25}\)H\(_{32}\)N\(_2\)O\(_4\) Rhnycophylline for thin-layer chromatography. It meets the following requirements.

Absorbance \( < 2.24\% \): \( E_{1\%}^{1\text{cm}} \) (245 nm): 473 – 502 (5 mg of the dried substance in a desiccator (silica gel) for 24 hours, a mixture of methanol and dilute acetic acid (7:3), 500 mL).

Purity Related substances—Dissolve 5 mg of rhnycophylline for assay in 100 mL of a mixture of methanol and dilute acetic acid (7:3), and use this solution as the sample
solution. Pipet 1 mL of the sample solution, add a mixture of methanol and dilute acetic acid (7:3) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid-chromatography 2.07 according to the following conditions. Determine the peak area of each solution by the automatic integration method: the total area of the peaks other than rhyncophylline obtained from the sample solution is not larger than the peak area of rhyncophylline from the standard solution.  

Operating conditions  
Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay under Uncaria Hook.  
Time span of measurement: About 4 times as long as the retention time of rhyncophylline, beginning after the solvent peak.  
System suitability  
Test for required detectability: Pipet 1 mL of the standard solution, add a mixture of methanol and dilute acetic acid (7:3) to make exactly 20 mL. Confirm that the peak area of rhyncophylline obtained with 20 μL of this solution is equivalent to 3.5 to 6.5% of that with 20 μL of the standard solution.  
System performance and system repeatability: Proceed as directed in the system suitability in the Assay under Uncaria Hook.  

Rhyncophylline for component determination  
See rhyncophylline for assay.  

Rhyncophylline for thin-layer chromatography  
C_{22}H_{28}N_{2}O_{4} White crystals or crystalline powder. Slightly soluble in ethanol (95.5) and in acetone, and practically insoluble in water. Melting point: 205 – 209°C.  
Identification—Determine the absorption spectrum of a solution of rhyncophylline for thin-layer chromatography in a mixture of methanol and dilute acetic acid (7:3) (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry 2.24: it exhibits a maximum between 242 nm and 246 nm.  
Purity Related substances—Dissolve 1.0 mg of rhyncophylline for thin-layer chromatography in 1 mL of acetone, and use this solution as the sample solution. Perform the test with this solution as directed under Thin-layer Chromatography 2.03. Spot 10 μL of the sample solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography and develop the plate with a mixture of 1-butanol, water and acetic acid (100) (7:2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): no spot other than the principal spot at around Rf 0.5 appears.  

Riboflavin C_{17}H_{20}N_{4}O_{6} [Same as the namesake monograph]  
Riboflavin sodium phosphate C_{17}H_{28}N_{4}NaO_{6}P [Same as the namesake monograph]  
Risperidone for assay C_{23}H_{27}FN_{4}O_{2} [Same as the monograph Risperidone. It contains not less than 99.5% of risperidone (C_{18}H_{16}O_{8}N), calculated on the dried basis.]  
Ritodrine hydrochloride C_{17}H_{20}NO_{3}.HCl [Same as the namesake monograph]  

Rose Bengal  
See Microbial Limit Test for Crude Drugs 5.02.  
Rose Bengal TS  
See Microbial Limit Test for Crude Drugs 5.02.  

Rosmarinic acid for assay  
Rosmarinic acid for thin-layer chromatography. However, it meets the following requirements:  
Absorbance 2.24 E_{1\%}^{254 nm} (325 nm): 502 – 534 (5 mg, water, 500 mL).  
Purity Related substances—Conduct this procedure using light-resistant vessels. Dissolve 5 mg of rosmarinic acid for assay in 20 mL of the mobile phase, and use this as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 50 mL, and use this as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography 2.07 according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than rosmarinic acid from the sample solution is not larger than the peak area of rosmarinic acid from the standard solution.  
Operating conditions  
Detector: An ultraviolet absorption photometer (wavelength: 240 nm).  
Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).  
Column temperature: A constant temperature of about 40°C.  
Mobile phase: A mixture of water, acetonitrile and phosphoric acid (800:200:1).  
Flow rate: Adjust the flow rate so that the retention time of rosmarinic acid is about 14 minutes.  
Time span of measurement: About 4 times as long as the retention time of rosmarinic acid.  
System suitability  
Test for required detectability: Pipet 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of rosmarinic acid obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.  
System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of rosmarinic acid are not less than 5000 and not more than 1.5, respectively.  
System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of rosmarinic acid is not more than 1.5%.  

Rosmarinic acid for component determination  
See rosmarinic acid for assay.  

Rosmarinic acid for thin-layer chromatography  
C_{18}H_{16}O_{8} White to pale yellow crystals or crystalline powder. Freely soluble in ethanol (99.5), and slightly soluble in water. Melting point: about 170°C (with decomposition).  
Identification—Determine the absorption spectrum of a solution of rosmarinic acid for thin-layer chromatography (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry 2.24: it exhibits maxima between 215 nm and 219 nm and between 322 nm and 326 nm.
### Reagents, Test Solutions / General Tests

**Purity**  
Related substances—Conduct this procedure using light-resistance vessels. Dissolve 10 mg of rosmarinic acid for thin-layer chromatography in 2 mL of ethanol (99.5), and use this solution as the sample solution. Pipet 1 mL of the sample solution, add ethanol (99.5) to make exactly 50 mL, and use this solution as the standard solution. Proceed with 10 \( \mu L \) each of the sample solution and standard solution as directed in the Identification (2) under Hangekobukuto Extract: the spot other than the principal spot of around RF 0.5 from the sample solution is not more intense than the spot from the standard solution.

**Rosaxidine acetate hydrochloride**  
C\(_{19}\)H\(_{28}\)N\(_2\)O\(_4\).HCl  
[Same as the namesake monograph]

**RPMI-1640 powdered medium**  
Powder medium for cell culture containing 6 g of sodium chloride, 400 mg of potassium chloride, 800 mg of sodium dihydrogen phosphate, 100 mg of anhydrous calcium nitrate, 49 mg of anhydrous magnesium sulfate, 2 g of dextrose, 200 mg of L-arginine, 1 mg of glutathione, 50 mg of L-isoleucine, 15 mg of L-phenylalanine, 5 mg of L-tryptophan, 0.2 mg of biotin, 1 mg of nicotinamide, 1 mg thiamine hydrochloride, 300 mg of L-glutamine, 56.8 mg of L-asparagine, 10 mg of glycine, 50 mg of L-leucine, 20 mg of L-proline, 20 mg of L-lysine, 0.25 mg of \( \text{Ca}^{2+} \) calcium pantothenate, 5 \( \mu g \) of cyano-cobalamin, 1 mg of aminobenzoic acid, 20 mg of L-aspartic acid, 15 mg of L-histidine, 40 mg of L-lysine hydrochloride, 30 mg of L-serine, 20 mg of L-valine, 1 mg of folic acid, 1 mg of pyridoxine hydrochloride, 20 mg of L-glutamic acid, 20 mg of L-hydroxyproline, 15 mg of L-methionine, 20 mg of L-threonine, 3 mg of choline chloride, 35 mg of \( \text{I}^{-} \) I-insoluble in water.

**Saccharated pepsin**  
[Same as the namesake monograph]

**Saikosaponin a for assay**  
Use saikosaponin a for thin-layer chromatography meeting the following additional specifications.

**Purity**  
Related substances—

1. Dissolve 2.0 mg of saikosaponin a for assay in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 100 mL, and use this as the standard solution. Proceed the test with exactly 10 \( \mu L \) each of the sample solution and standard solution as directed in the Purity (2) under Bupleurum Root: the spot other than the principal spot around RF 0.4 is not larger and not more intense than the spot obtained with the standard solution.

2. Dissolve 10 mg of saikosaponin a for assay in 20 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 100 mL, and use this as the standard solution. Perform the test with exactly 20 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01>\) according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than saikosaponin a is not more than the peak area of saikosaponin a obtained with the standard solution.

**Operating conditions**

Detector, column: Proceed as directed in the operating conditions in the Assay under Bupleurum Root.

Column temperature: A constant temperature of about 40°C.

**Mobile phase** A mixture of water and acetonitrile (13:7).

**Flow rate** Adjust the flow rate so that the retention time of saikosaponin a is about 16 minutes.

**Time span of measurement** About 6 times as long as the retention time of saikosaponin a beginning after the solvent peak.

**System suitability**

Test for required detectability: Measure exactly 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of saikosaponin a obtained with 20 \( \mu L \) of this solution is equivalent to 3.5 to 6.5% of that with 20 \( \mu L \) of the standard solution.

**System performance** Dissolve 6 mg each of saikosaponin a for assay and saikosaponin b\(_2\) for assay in methanol to make 100 mL. When the procedure is run with 20 \( \mu L \) of the standard solution under the above operating conditions, saikosaponin a and saikosaponin b\(_2\) are eluted in this order with the resolution between these peaks being not less than 1.5.

**System repeatability** When the test is repeated 6 times with 20 \( \mu L \) of the standard solution under the above operating conditions, the relative standard deviation of the peak area of saikosaponin a is not more than 1.0%.

**Saikosaponin a for component determination** See saikosaponin a for assay.

**Saikosaponin a for thin-layer chromatography** A white, crystalline powder or powder. Freely soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: 225–232°C (decomposition).

**Absorbance** \(<2.01>\) \( E_{1%}^{\text{cm}} \) (206 nm): 60–68 (15 mg, methanol, 200 mL). Previously dried in a desiccator (in vacuum, silica gel) for 24 hours.

**Purity** Related substances—Dissolve 1.0 mg of saikosaponin a for thin-layer chromatography in exactly 1 mL of methanol, and perform the test with 10 \( \mu L \) of this solution as directed in the Identification (2) under Bupleurum Root: any spot other than the principal spot at the RF value of about 0.4 does not appear.

**Saikosaponin b\(_2\) for assay** C\(_{42}\)H\(_{68}\)O\(_{13}\) Saikosaponin b\(_2\) for thin-layer chromatography. It meets the following requirements.

**Purity** Related substances—Dissolve 5 mg in 5 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 10 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01>\) according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than the peaks of saikosaponin b\(_2\) and solvent obtained from the sample solution is not larger than the peak area of saikosaponin b\(_2\) from the standard solution.

**Operating conditions**

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay (1) under Saireito Extract.

**Time span of measurement** About 6 times as long as the retention time of saikosaponin b\(_2\).

**System suitability**

Test for required detectability: To exactly 1 mL of the
standard solution add the mobile phase to make exactly 20 mL. Confirm that the peak area of saikosaponin d obtained from 10 µL of this solution is equivalent to 3.5 to 6.5% of that from 10 µL of the standard solution.

System performance, and system repeatability: Proceed as directed in the system suitability in the Assay (1) under Saireito Extract.

**Saikosaponin b₂ for component determination** See saikosaponin b₂ for assay.

**Saikosaponin b₂ for thin-layer chromatography**

C₂₂H₄₀O₁₃ White crystals or crystalline powder. Freely soluble in ethanol (99.5), soluble in methanol, and practically insoluble in water. Melting point: about 240°C

Absorbance \( \leq 0.3 \) (252 nm): 35 – 424 [5 mg dried in a desiccator (in vacuum, silica gel) for 24 hours, methanol, 250 mL].

**Purity** Related substances—Dissolve 2 mg in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 50 mL, and use this solution as the standard solution. Proceed the test with 10 µL each of the sample solution and standard solution as directed in the Identification (1) under Saireito Extract: the spot other than the principal spot, having \( Rf \) value of about 0.3, obtained from the sample solution is not more intense than the spot from the standard solution.

**Saikosaponin d for assay** C₂₂H₄₀O₁₃ A white, crystalline powder or powder. Freely soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: about 240°C.

Absorbance \( \leq 0.3 \) (206 nm): 63 – 71 (15 mg, methanol, 200 mL). Previously dried in a desiccator (in vacuum, silica gel) for 24 hours.

**Purity** Related substances—

(1) Dissolve 2.0 mg in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 100 mL, and use this as the standard solution. Proceed the test with 10 µL each of the sample solution and standard solution as directed in the Identification (1) under Saireito Extract: the spot other than the principal spot around \( Rf \) 0.4 is not larger and not more intense than the spot obtained from the sample solution.

(2) Dissolve 10 mg in 20 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 100 mL, and use this as the standard solution. Perform the test with exactly 20 µL each of the sample solution and standard solution as directed under Liquid Chromatography \( < 2.01 \) according to the following conditions, and determine each peak area by the automatic integration method: the total area of the peaks other than saikosaponin d and the solvent is not more than the peak area of saikosaponin d obtained with the standard solution.

Operating conditions

Detector, and column: Proceed as directed in the operating conditions in the Assay under Bupleurum Root.

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of water and acetonitrile (11:9).

Flow rate: Adjust the flow rate so that the retention time of saikosaponin d is about 13 minutes.

Time span of measurement: About 4 times as long as the retention time of saikosaponin d beginning after the solvent peak.

System suitability

Test for required detectability: Measure exactly 1 mL of the standard solution, and add methanol to make exactly 20 mL. Confirm that the peak area of saikosaponin d obtained with 20 µL of this solution is equivalent to 3.5 to 6.5% of that with 20 µL of the standard solution.

System performance: Dissolve 6 mg each of saikosaponin d for assay and saikosaponin a for assay in methanol to make 100 mL. When the procedure is run with 20 µL of the standard solution under the above operating conditions, saikosaponin a and saikosaponin d are eluted in this order with the resolution between these peaks being not less than 1.5.

System repeatability: When the test is repeated 6 times with 20 µL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of saikosaponin d is not more than 1.0%.

**Saikosaponin d for component determination** See saikosaponin d for assay.

**Salicylaldazine** C₁₄H₁₂N₂O₂ Dissolve 0.30 g of hydrazinium sulfate in 5 mL of water. To this solution add 1 mL of acetic acid (100) and 2 mL of a freshly prepared solution of salicylaldehyde in 2-propanol (1 in 5), shake well, and allow to stand until a yellow precipitate is produced. Extract with two 15 mL portions of dichloromethane, to the combined dichloromethane extracts add 5 g of anhydrous sodium sulfate, shake, decant or filter, and evaporate the dichloromethane in the supernatant liquid or filtrate. Dissolve the residue in a warmed mixture of toluene and methanol (3:2), and cool. Filter the crystals produced, and dry in a desiccator (in vacuum, silica gel) for 24 hours. It is a yellow, crystalline powder.

Melting point \( \leq 213 – 219°F \)

**Purity** Related substances—Dissolve 0.09 g of salicylaldehyde in toluene to make exactly 100 mL. Pipet 1 mL of this solution, add toluene to make exactly 100 mL, and perform the test with this solution as directed in the Purity (6) under Povidone: any spot other than the principal spot does not appear.

**Salicylaldehyde** HOC₆H₄CHO [K 8390, Special class]

**Salicylamide** C₅H₄NO₂ White crystals or crystalline powder, and it is odorless and tasteless. Very soluble in N,N-dimethylformamide, freely soluble in ethanol (95%), soluble in propylene glycol, sparingly soluble in diethyl ether, and slightly soluble in water and in chloroform. It dissolves in sodium hydroxide TS.

Melting point \( \leq 139 – 143°C \)

**Purity** Ammonium \( < 1.02 \)—Shake 1.0 g of salicylamide with 40 mL of water, and filter through filter paper previously washed well with water. Discard the first 10 mL of the filtrate, transfer the subsequent 20 mL to a Nessler tube, and add water to make 30 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: transfer 2.5 mL of Standard Ammonium Solution to a Nessler tube, and add water to make 30 mL.

Loss on drying \( \leq 0.40 \): not more than 0.5% (1 g, silica gel, 4 hours).

Residue on ignition \( \leq 0.44 \): not more than 0.1% (1 g).

Content: not less than 98.5%. Assay—Weigh accurately
about 0.2 g of salicylamide, previously dried, dissolve in 70 mL of N,N-Dimethylformamide, and titrate $<2.50$ with 0.1 mol/L tetramethylammonium hydroxide VS (potentiometric titration). Separately, perform a blank determination with a solution of 70 mL of N,N-Dimethylformamide in 15 mL of water, and make any necessary correction.

Each mL of 0.1 mol/L tetramethylammonium hydroxide VS = 13.71 mg of CH$_3$NO$_2$.

**Salicylic acid** HOC$_6$H$_4$COOH [K 8392, Special class]

**Salicylic acid for assay** HOC$_6$H$_4$COOH [K 8392, Special class]

**Salicylic acid TS** Dissolve 0.1 g of salicylic acid in 10 mL of sulfuric acid. Prepare before use.

**Santonin** C$_{15}$H$_{18}$O$_3$ [Same as the namesake monograph]

**Santonin for assay** [Same as the monograph Santonin. It contains not less than 99.0% of santonin (C$_{15}$H$_{18}$O$_3$).]

**Sarpogrelate hydrochloride** C$_{24}$H$_{31}$NO$_6$.HCl [Same as the namesake monograph]

**Schisandrin for thin-layer chromatography** C$_{24}$H$_{32}$O$_7$ [Same as the namesake monograph]

**Scopolamine hydrobromide** See scopolamine hydrobromide hydrate.

**Scopolamine hydrobromide for thin-layer chromatography** See scopolamine hydrobromide hydrate for thin-layer chromatography.

**Scopolamine hydrobromide hydrate** C$_{17}$H$_{21}$NO$_4$.HBr.3H$_2$O [Same as the namesake monograph]

**Scopolamine hydrobromide hydrate for thin-layer chromatography** C$_{17}$H$_{21}$NO$_4$.HBr.3H$_2$O [Same as the monograph Scopolamine Hydrobromide Hydrate. Proceed as directed in the Identification (3) under Opium Alkaloids and Atropine Injection: any spot other than the principal spot at the $R_f$ value of about 0.4 does not appear.]

**Scopolamine hydrobromide** See scopolamine hydrobromide hydrate.

**Scopolamine hydrobromide for thin-layer chromatography** See scopolamine hydrobromide hydrate for thin-layer chromatography.

**Scopolamine hydrobromide hydrate** C$_{17}$H$_{21}$NO$_4$.HBr.3H$_2$O [Same as the namesake monograph]

**Scopolamine hydrobromide hydrate for thin-layer chromatography** C$_{17}$H$_{21}$NO$_4$.HBr.3H$_2$O [Same as the monograph Scopolamine Hydrobromide Hydrate. Proceed as directed in the Identification (3) under Opium Alkaloids and Atropine Injection: any spot other than the principal spot at the $R_f$ value of about 0.7 does not appear.]

**Sea sand** A mixture of white, grey, brown or black grains, 0.3 to 1.0 mm in particle size.

**2nd Fluid for disintegration test** To 250 mL of 0.2 mol/L potassium dihydrogen phosphate TS add 118 mL of 0.2 mol/L sodium hydroxide TS and water to make 1000 mL. It is clear and colorless, and has a pH about 6.8.

**2nd Fluid for dissolution test** A mixture of phosphate buffer solution, pH 6.8 and water (1:1).

**Selenious acid** H$_2$SeO$_3$ Colorless or white crystals. It is hygroscopic.

**Identification**—(1) Dissolve 0.2 g of selenious acid in 20 mL of water, and use this as the sample solution. To 10 mL of the sample solution add 2 mL of tin (II) chloride TS: a red precipitate is produced.

(2) To 10 mL of the sample solution obtained in (1) add 1 mL of diluted hydrochloric acid (2 in 3) and 1 mL of potassium iodide TS: a brown color is produced.

Preserve in a light-resistant tight container.

**Selenium** Se [K 8598, Special class]

**Selenium dioxide** SeO$_2$ White crystals or crystalline powder.

**Identification**—(1) To 10 mL of a solution of selenium dioxide (1 in 100) add 2 mL of tin (II) chloride TS: a red precipitate is produced.

(2) To 10 mL of a solution of selenium dioxide (1 in 100) add 1 mL of diluted hydrochloric acid (2 in 3) and 1 mL of potassium iodide TS: a brown color is produced.

**Content**: not less than 97.0%. Assay—Weigh accurately about 0.6 g of selenium dioxide, and dissolve in water to make exactly 200 mL. Pipet 20 mL of this solution into an iodine bottle, add 80 mL of water, 3 g of potassium iodide and 5 mL of diluted hydrochloric acid (2 in 3), allow to stand at a dark place for 5 minutes, and titrate $<2.50$ with 0.1 mol/L sodium thiosulfate VS (indicator: starch TS). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium thiosulfate VS = 2.774 mg of SeO$_2$.

**Semicarbazide acetate TS** Place 2.5 g of semicarbazide hydrochloride, 2.5 g of anhydrous sodium acetate and 30 mL of methanol in a flask, heat on a water bath for 2 hours, cool to 20°C, and filter. To the filtrate add methanol to make 100 mL. Preserve in a cold place. Do not use the solution showing a yellow color.

**Semicarbazide hydrochloride** H$_2$NNHCONH$_2$.HCl White to light yellow crystals.

**Identification** (1) To 10 mL of a solution of semicarbazide hydrochloride (1 in 100) add 1 mL of silver nitrate TS: white precipitates appear.

(2) Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry $<2.25$: it exhibits absorption at the wave numbers of about 3420 cm$^{-1}$, 3260 cm$^{-1}$, 2670 cm$^{-1}$, 1684 cm$^{-1}$, 1582 cm$^{-1}$, 1474 cm$^{-1}$, 1386 cm$^{-1}$, 1210 cm$^{-1}$, 1181 cm$^{-1}$, 770 cm$^{-1}$ and 719 cm$^{-1}$.

**Sennoside A for thin-layer chromatography** C$_{20}$H$_{18}$O$_{20}$ Yellow crystalline powder. Insoluble in water, in chloroform and in diethyl ether, and practically insoluble in methanol and in acetone. Melting point: 200 – 240°C (with decomposition).

**Purity** Related substances—Dissolve 1.0 mg of sennoside A for thin-layer chromatography in exactly 4 mL of a mixture of tetrahydrofuran and water (7:3), and perform the test with 80 µL of this solution as directed in the identification under Rhubarb: any spot other than the principal spot at the $R_f$ value of about 0.3 does not appear.

**L-Serine** C$_3$H$_7$NO$_3$ [K 9105, Special class]

**Sesamin for thin-layer chromatography** C$_{20}$H$_{18}$O$_6$
White crystals or crystalline powder. Slightly soluble in methanol and in ethanol (99.5), and practically insoluble in water.

**Melting point** 2<sub>60</sub>: 122 - 124°C

**Identification** Determine the absorption spectrum of a solution of Sesame in methanol (3 in 200,000) as directed under Ultra violet-visible Spectrophotometry 2<sub>240</sub>**: it exhibits maxima between 235 nm and 239 nm and between 285 nm and 289 nm.

**Purity** Related substances—Dissolve 2.0 mg in 2 mL of methanol, and use this as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 50 mL, and use this as the standard solution. Perform the test with 5 μL each of the sample solution and standard solution as directed in the Identification under Sesame: the spot other than the principal spot obtained from the sample solution is not more intense than the spot from the standard solution.

**6]-Shogaol for assay** C<sub>17</sub>H<sub>24</sub>O<sub>3</sub> **[6]-Shogaol for thin-layer chromatography. It meets the following requirements. Absorbance 2<sub>240</sub>: E<sub>240</sub> (225 nm): 727 - 781 (5 mg, ethanol (99.5), 500 mL).**

**Purity** Related substances—Dissolve 5 mg of [6]-shogaol for assay in 10 mL of a mixture of acetonitrile and water (2:1), and use this solution as the sample solution. Pipet 1 mL of the sample solution, add a mixture of acetonitrile and water (2:1) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography 2<sub>0.1</sub>** according to the following conditions. Determine the peak area of each solution by the automatic integration method: the total area of the peaks other than [6]-shogaol obtained form the sample solution is not larger than the peak area of [6]-shogaol from the standard solution.

**Operating conditions**
- Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions under Assay (2) of Mukoi-Daikenchuto Extract.
- Time span of measurement: 3 times as long as the retention time of [6]-shogaol, beginning after the solvent peak.

**System suitability**
- Test for required detectability: Pipet 1 mL of the standard solution, and add a mixture of acetonitrile and water (2:1) to make exactly 20 mL. Confirm that the peak area of [6]-shogaol obtained with 10 μL of this solution is equivalent to 3.5 to 6.5% of that with 10 μL of the standard solution.
- System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of [6]-shogaol are not less than 5000 and not more than 1.5%, respectively.

**System repeatability:** When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of [6]-shogaol is not more than 1.5%.

**[6]-Shogaol for thin-layer chromatography** C<sub>17</sub>H<sub>24</sub>O<sub>3</sub> **A pale yellow oil. Miscible with methanol, ethanol (99.5) and with diethyl ether, and practically insoluble in water.**

**Purity** Related substances—Dissolve 1.0 mg of [6]-shogaol for thin-layer chromatography in 2 mL of methanol, and perform the test with this solution as directed under Thin-layer Chromatography 2<sub>60</sub>. Spot 10 μL on a plate of silica gel for thin-layer chromatography, develop the plate with a mixture of ethyl acetate and hexane (1:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly 4-dimethylaminobenzaldehyde TS on the plate, heat at 105°C for 5 minutes, and allow to cool: no spot other than the principal spot at around R<sub>f</sub> 0.5 appears.

**Silica gel** An amorphous, partly hydrated silicic acid occurring in glassy granules of various sizes. When used as a desiccant, it is frequently coated with a substance that changes color when the capacity to absorb water is exhausted. Such colored products may be regenerated by being heated at 110°C until the gel assumes the original color.

**Loss on ignition** 2<sub>43</sub>: not more than 5% (2 g, 950 ± 50°C).

**Water absorption:** not less than 31%. Weigh accurately about 10 g of silica gel, and allow to stand for 24 hours in a closed container in which the atmosphere is maintained at 80% relative humidity with sulfuric acid having a specific gravity of 1.19. Weigh again, and calculate the increase in mass.

**Siliceous earth** [K 8330, Diatomaceous earth, First class]

**Silicone oil** Colorless clear liquid, having no odor. **Viscosity** 2<sub>53</sub>: 50 - 100 mm²/s.

**Silicone resin** Light gray, half-clear, viscous liquid or a pasty material. It is almost odorless.

**Viscosity and refractive index**—Place 15 g of silicone resin in a Soxhlet extractor, then extract with 150 mL of carbon tetrachloride for 3 hours. The kinematic viscosity of the residual liquid, obtained by evaporating carbon tetrachloride from the extract on a water bath, is 100 to 1100 mm²/s (25°C). Its refractive index is 1.400 to 1.410 (25°C).

**Specific gravity** 2<sub>50</sub>: d<sub>25</sub> 0.98 – 1.02

**Loss on drying** 2<sub>43</sub>: 0.45 – 2.25 g with the extracted residue obtained in the Viscosity and refractive index (100°C, 1 hour).

**Silicic acid 26-water** SiO<sub>2</sub>·12WO<sub>3</sub>·26H<sub>2</sub>O
White to slightly yellowish, crystals. Deliquescent. Very soluble in water and in ethanol (95).

**Purity** Clarity and color of solution—a solution (1 in 20) is clear and colorless.

**Loss on ignition** 2<sub>43</sub>: 14 – 15% (2 g, dry at 110°C for 2 hours then 700 – 750°C, constant mass).

**Silver chromate-saturated potassium chromate TS** Dissolve 5 g of potassium chromate in 50 mL of water, add silver nitrate TS until a pale red precipitate is produced, and filter. To the filtrate add water to make 100 mL.

**Silver diethyldithiocarbamate** See silver N,N-diethyldithiocarbamate.

**Silver nitrate** AgNO<sub>3</sub> [K 8550, Special class]

**Silver nitrate-ammonia TS** Dissolve 1 g of silver nitrate in 20 mL of water, and add ammonia TS dropwise with stirring until the precipitate is almost entirely dissolved.

**Storage**—Preserve in tight, light-resistant containers.

**Silver nitrate TS** Dissolve 17.5 g of silver nitrate in water to make 1000 mL (0.1 mol/L). Preserve in light-resistant containers.

**Silver N,N-diethyldithiocarbamate** C<sub>10</sub>H<sub>16</sub>AgNS<sub>2</sub>
Sodium carbonate, anhydrous Na₂CO₃ [K 8625, Sodium carbonate, Special class]

Sodium carbonate dechydrate Na₂CO₃·10H₂O [K 8624, Special class]

Sodium carbonate for pH determination Na₂CO₃ [K 8625, for pH determination]

Sodium carbonate (standard reagent) Na₂CO₃ [K 8005, Standard reagent for volumetric analysis]

Sodium carbonate TS Dissolve 10.5 g of anhydrous sodium carbonate in water to make 100 mL (1 mol/L).

0.55 mol/L Sodium carbonate TS Dissolve 5.83 g of anhydrous sodium carbonate in water to make 100 mL.

Sodium chloride NaCl [K 8150, Special class]

Sodium chloride (standard reagent) NaCl [K 8005, Standard reagent for volumetric analysis]

Sodium chloride TS Dissolve 10 g of sodium chloride in water to make 100 mL.

0.1 mol/L Sodium chloride TS Dissolve 6 g of sodium chloride in water to make 1000 mL.

0.2 mol/L Sodium chloride TS Dissolve 11.7 g of sodium chloride in water to make 1000 mL.

1 mol/L Sodium chloride TS Dissolve 29.22 g of sodium chloride in water to make 500 mL.

Sodium citrate See sodium citrate hydrate.

Sodium citrate hydrate C₆H₅Na₃O₇·2H₂O [K 8288, Trisodium citrate dihydrate, or same as the namesake monograph]

Sodium cobaltinitrite See sodium hexanitrocobaltate (III).

Sodium cobaltinitrite TS See sodium hexanitrocobaltate (III) TS.

Sodium 1-decanesulfonate C₁₀H₂₁NaO₄ White powder.

Purity Clarity and color of solution—Dissolve 1.0 g in 20 mL of water: the solution is clear and colorless. Loss on drying <2.4%: not more than 3.0% (1 g, 105°C, 3 hours).

Content: not less than 98.0%. Assay—Weigh accurately 0.45 g of sodium 1-decanesulfonate, dissolve in 50 mL of water, and pass through a column, about 1.2 cm in inside diameter and about 25 cm in length, packed with about 20 mL of strongly acidic ion-exchange resin (0.3 to 1.0 mm, H type) at a flow rate of about 4 mL per minute. Wash with 150 mL of water at a flow rate of about 4 mL per minute. Combine the washing and the elute, and titrate <2.3% with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium thiosulfate VS = 0.4729 mg of NaBH₄

Sodium bromide NaBr [K 8514, Special class]

Sodium carbonate See sodium carbonate dechydrate.

Sodium carbonate, anhydrous Na₂CO₃ [K 8625, Sodium carbonate, Special class]

Sodium carbonate dechydrate Na₂CO₃·10H₂O [K 8624, Special class]

Sodium carbonate for pH determination Na₂CO₃ [K 8625, for pH determination]

Sodium carbonate (standard reagent) Na₂CO₃ [K 8005, Standard reagent for volumetric analysis]

Sodium carbonate TS Dissolve 10.5 g of anhydrous sodium carbonate in water to make 100 mL (1 mol/L).

0.55 mol/L Sodium carbonate TS Dissolve 5.83 g of anhydrous sodium carbonate in water to make 100 mL.

Sodium chloride NaCl [K 8150, Special class]

Sodium chloride (standard reagent) NaCl [K 8005, Standard reagent for volumetric analysis]

Sodium chloride TS Dissolve 10 g of sodium chloride in water to make 100 mL.

0.1 mol/L Sodium chloride TS Dissolve 6 g of sodium chloride in water to make 1000 mL.

0.2 mol/L Sodium chloride TS Dissolve 11.7 g of sodium chloride in water to make 1000 mL.

1 mol/L Sodium chloride TS Dissolve 29.22 g of sodium chloride in water to make 500 mL.

Sodium citrate See sodium citrate hydrate.

Sodium citrate hydrate C₆H₅Na₃O₇·2H₂O [K 8288, Trisodium citrate dihydrate, or same as the namesake monograph]

Sodium cobaltinitrite See sodium hexanitrocobaltate (III).

Sodium cobaltinitrite TS See sodium hexanitrocobaltate (III) TS.

Sodium 1-decanesulfonate C₁₀H₂₁NaO₄ White powder.

Purity Clarity and color of solution—Dissolve 1.0 g in 20 mL of water: the solution is clear and colorless. Loss on drying <2.4%: not more than 3.0% (1 g, 105°C, 3 hours).

Content: not less than 98.0%. Assay—Weigh accurately 0.45 g of sodium 1-decanesulfonate, dissolve in 50 mL of water, and pass through a column, about 1.2 cm in inside diameter and about 25 cm in length, packed with about 20 mL of strongly acidic ion-exchange resin (0.3 to 1.0 mm, H type) at a flow rate of about 4 mL per minute. Wash with 150 mL of water at a flow rate of about 4 mL per minute. Combine the washing and the elute, and titrate <2.3% with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium thiosulfate VS = 0.4729 mg of NaBH₄

Sodium bromide NaBr [K 8514, Special class]

Sodium carbonate See sodium carbonate dechydrate.
crystalline powder.

Identification—Determine the infrared absorption spectrum of sodium desoxycholate, previously dried, according to the potassium bromide disk method under Infrared Spectrophotometry $\leq 2.25\%$: it exhibits absorption at the wave numbers of about 3400 cm$^{-1}$, 2940 cm$^{-1}$, 1562 cm$^{-1}$ and 1408 cm$^{-1}$.

Purity Related substances—Dissolve 0.10 g of sodium desoxycholate in 10 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of this solution, add methanol to make exactly 100 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography $\leq 2.0\%$. Spot 10 $\mu$L each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, methanol and acetic acid (100:80:40:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly concentrated sulfuric acid on the plate, and heat at 105°C for 10 minutes: the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

Sodium 2,6-dichloroindophenol-sodium acetate TS Mix before use an equal volume of sodium 2,6-dichloroindophenol dehydrate solution (1 in 20) and acetic acid-sodium acetate TS, pH 7.0.

Sodium diethyldithiocarbamate See sodium $N,N$-diethyldithiocarbamate trihydrate.

Sodium $N,N$-diethyldithiocarbamate trihydrate $(C_2H_5)_2NCS_2Na_3H_2O$ [K 8454, Special class]

Sodium di-2-ethylhexyl sulfosuccinate $C_{18}H_{33}COOCH_2(C_9H_17COO)CHSO_3Na$ White or translucent white mucilaginous soft masses. Sparingly soluble in water.

Purity Clarity and color of solution—A solution prepared by dissolving 1.0 g in 100 mL of water is clear and colorless.

Loss on drying $\leq 2.4\%$: not more than 5.0% (1 g, 105°C, 2 hours).

Sodium dihydrogen phosphate See sodium dihydrogen phosphate dihydrate.

Sodium dihydrogen phosphate anhydrous $NaH_2PO_4$ A white, powder or crystalline powder. Freely soluble in water, and very slightly soluble in ethanol (99.5). It has a hygroscopic property.

A solution is acidic.

Sodium dihydrogen phosphate dihydrate $NaH_2PO_4\cdot2H_2O$ [K 9009, Special class]

Sodium dihydrogen phosphate TS, pH 2.2 Dissolve 1.56 g of sodium dihydrogen phosphate dihydrate in 800 mL of water, adjust the pH to 2.2 with phosphoric acid, and add water to make 1000 mL.

Sodium dihydrogen phosphate TS, pH 2.5 Dissolve 2.7 g of sodium dihydrogen phosphate dihydrate in 1000 mL of water, and adjust the pH to 2.5 with phosphoric acid.

0.05 mol/L Sodium dihydrogen phosphate TS, pH 2.6 Dissolve 7.80 g of sodium dihydrogen phosphate dihydrate in 900 mL of water, adjust the pH to exactly 2.6 and add water to make 1000 mL.

0.05 mol/L Sodium dihydrogen phosphate TS, pH 3.0 Dissolve 3.45 g of sodium dihydrogen phosphate dihydrate in 500 mL of water (solution A). Dilute 2.45 g of phosphoric acid with water to make 500 mL (solution B). To a volume of solution A add solution B until the mixture is adjusted to pH 3.0.

0.1 mol/L Sodium dihydrogen phosphate TS, pH 3.0 Dissolve 15.60 g of sodium dihydrogen phosphate dihydrate in 900 mL of water, adjust the pH to 3.0 with phosphoric acid, and add water to make 1000 mL.

0.05 mol/L Sodium dihydrogen phosphate TS Dissolve 7.80 g of sodium dihydrogen phosphate dihydrate in water to make 1000 mL.

0.1 mol/L Sodium dihydrogen phosphate TS Dissolve 7.80 g of sodium dihydrogen phosphate dihydrate in 450 mL of water, adjust to a pH of 5.8 exactly with sodium hydroxide TS, and add water to make 500 mL.

2 mol/L Sodium dihydrogen phosphate TS Dissolve 312.02 g of sodium dihydrogen phosphate dihydrate in water to make 1000 mL.

Sodium disulfite $Na_2S_2O_5$ [K 8501, First class]

Sodium disulfite TS Dissolve 0.10 g of sodium disulfite in 10 mL of 1 mol/L hydrochloric acid TS, and add acetone to make 100 mL.

Sodium dithionite $Na_2S_2O_4$ A white to grayish white crystalline powder, having a strong irritating odor. It is decomposed with moisture or atmospheric oxygen.

Identification—(1) Dissolve 0.5 g of sodium dithionite in 50 mL of water, and use this as the sample solution. To 10 mL of the sample solution add 1 mL of copper (II) sulfate TS: a grayish brown color is produced.

(2) The sample solution obtained in (1) responds to the Qualitative Tests $\leq 1.09\%$ (1) for sodium salt. Preserve in a light-resistant tight container.

Sodium dodecylbenzene sulfonate $C_{18}H_{29}SO_3Na$ White, crystalline powder or mass. $\rho \geq 2.34\%$: The pH of a solution of 0.5 g of sodium dodecylbenzene sulfonate in 50 mL of freshly boiled and cooled water is between 5.0 and 7.0. Measure the pH at 25°C passing nitrogen with stirring.

Loss on drying $\leq 2.4\%$: not more than 0.5% (1 g, 105°C, 2 hours).

Content: not less than 99.0%. Assay—Weigh accurately about 40 mg of sodium dodecylbenzene sulfonate, previously dried, and perform the test as directed in (4) Sulfur in the Procedure of determination under Oxygen Flask Combustion Method $\leq 1.06\%$, using a mixture of 20 mL of water and 2 mL of strong hydrogen peroxide water as absorbing solution.

Each mL of 0.01 mol/L barium perchlorate VS = 1.742 mg of $C_{18}H_{29}SO_3Na$

Sodium fluoride $NaF$ [K 8821, Special class]

Sodium fluoride (standard reagent) $NaF$ [K 8005, Standard reagent for volumetric analysis]

Sodium fluoride TS Dissolve 0.5 g of sodium fluoride in 100 mL of 0.1 mol/L hydrochloric acid TS. Prepare before use.
Sodium glycocholate for thin-layer chromatography

\( \text{C}_{26}\text{H}_{42}\text{NNaO}_{6}\cdot\text{xH}_{2}\text{O} \) White to pale brown crystalline powder or powder. Freely soluble in water and in methanol, and slightly soluble in ethanol (99.5). Melting point: about 260°C (with decomposition).

**Identification**—Determine the infrared absorption spectrum of sodium glycocholate for thin-layer chromatography as directed in the potassium bromide disk method under Infrared Spectrophotometry (2.25a), it exhibits absorption at the wave numbers of about 2940 cm\(^{-1}\), 1640 cm\(^{-1}\), 1545 cm\(^{-1}\), 1450 cm\(^{-1}\), 1210 cm\(^{-1}\), 1050 cm\(^{-1}\), and 600 cm\(^{-1}\).

Optical rotation \( <2.49^\circ \) [\( \alpha \text{D}^2 \)]: +25° to +35° (60 mg, methanol, 20 mL, 100 mm).

**Purity** Related substances—Dissolve 5 mg of sodium glycocholate for thin-layer chromatography in 1 mL of methanol, and use this solution as the sample solution. Pipet 0.2 mL of this solution, add methanol to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography (2.03a). Proceed with 5 \( \mu \)L each of the sample solution and standard solution as directed in the Identification under Bear Bile: the spots other than the principal spot at the wave number of about 2940 cm\(^{-1}\) are not more intense than the spot from the standard solution more than about 0.2 obtained from the sample solution are not more intense than the spot from the standard solution.

**Sodium 1-heptane sulfonate** \( \text{C}_{7}\text{H}_{15}\text{NaO}_{3}\text{S} \) White, crystals or crystalline powder.

**Purity** Clarity and color of solution—Dissolve 1.0 g of sodium 1-heptane sulfonate in 10 mL of water: the solution is clear and colorless.

**Loss on drying** \( <2.41\% \): not more than 3.0% (1 g, 105°C, 3 hours).

**Content**: not less than 99.0%. Assay—Dissolve about 0.4 g of sodium 1-heptane sulfonate, previously dried and weighed accurately, in 50 mL of water, transfer to a chromatographic column, prepared by packing a chromatographic tube 9 mm in inside diameter and 160 mm in height with 10 mL of strongly acidic ion exchange resin for column chromatography (425 to 600 \( \mu \)m in particle diameter, \( \text{H}_2\text{O} \)), and flow at a flow rate of about 4 mL per minute. Wash the column at the same flow rate with 150 mL of type), and flow at a flow rate of about 4 mL per minute.

Each mL of 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of phenolphthalein TS).

Each mL of 0.1 mol/L sodium hydroxide VS = 18.82 mg of \( \text{C}_{7}\text{H}_{15}\text{NaO}_{3}\text{S} \)

**Sodium hexanitrocobaltate (III) \( \text{Na}_3\text{Co(NO}_2\text{)}_6 \) [K 8347, Special class]**

**Sodium hexanitrocobaltate (III) TS** Dissolve 10 g of sodium hexanitrocobaltate (III) in water to make 50 mL, and filter if necessary. Prepare before use.

**Sodium hydrogen carbonate** \( \text{NaHCO}_3 \) [K 8622, Special class]

**Sodium hydrogen carbonate for pH determination** \( \text{NaHCO}_3 \) [K 8622, Sodium hydrogen carbonate, for pH determination]

**Sodium hydrogen carbonate TS** Dissolve 5.0 g of sodium hydrogen carbonate in water to make 100 mL.

7% Sodium hydrogen carbonate injection See 7% sodium bicarbonate injection.

**Sodium hydrogen sulfite** [K 8059, Special class]

**Sodium hydrogen sulfite TS** Dissolve 10 g of sodium hydrogen sulfite in water to make 30 mL. Prepare before use.

**Sodium hydrogen tartrate monohydrate** \( \text{NaHC}_4\text{H}_4\text{O}_6\cdot\text{H}_2\text{O} \) [K 8538, Sodium hydrogentartrate monohydrate, Special class]

**Sodium hydrogen tartrate TS** Dissolve 1 g of sodium bitartrate in water to make 10 mL (0.5 mol/L). Prepare before use.

**Sodium hydroxide** \( \text{NaOH} \) [K 8576, Special class]

**Sodium hydroxide-dioxane TS** Dissolve 0.80 g of sodium hydroxide in a mixture of 1,4-dioxane and water (3:1) to make 100 mL.

**Sodium hydroxide-methanol TS** Dissolve by thorough shaking 4 g of sodium hydroxide in methanol to make 100 mL. To the supernatant liquid obtained by centrifugation add methanol to make 500 mL. Prepare before use.

**Sodium hydroxide TS** Dissolve 4.3 g of sodium hydroxide in water to make 100 mL (1 mol/L). Preserve in polyethylene bottles.

**Sodium hydroxide TS, dilute** Dissolve 4.3 g of sodium hydroxide in freshly boiled and cooled water to make 1000 mL. Prepare before use (0.1 mol/L).

0.01 mol/L Sodium hydroxide TS Dilute 10 mL of sodium hydroxide TS with water to make 1000 mL. Prepare before use.

0.05 mol/L Sodium hydroxide TS To 10 mL of 0.5 mol/L sodium hydroxide TS add water to make 100 mL.

0.2 mol/L Sodium hydroxide TS Dissolve 8.0 g of sodium hydroxide in freshly boiled and cooled water to make 1000 mL. Prepare before use.

0.5 mol/L Sodium hydroxide TS Dissolve 22 g of sodium hydroxide in water to make 1000 mL. Preserve in polyethylene bottles.
2 mol/L Sodium hydroxide TS  Dissolve 86 g of sodium hydroxide in water to make 1000 mL. Preserve in polyethylene bottles.

4 mol/L Sodium hydroxide TS  Dissolve 168 g of sodium hydroxide in water to make 1000 mL. Preserve in polyethylene bottles.

6 mol/L Sodium hydroxide TS  Dissolve 252 g of sodium hydroxide in water to make 1000 mL. Preserve in polyethylene bottles.

8 mol/L Sodium hydroxide TS  Dissolve 336 g of sodium hydroxide in water to make 1000 mL. Preserve in polyethylene bottles.

Sodium hypobromite TS  To 8 mL of bromine TS add 25 mL of water and 25 mL of sodium carbonate TS. Prepare before use.

Sodium hypochlorite-sodium hydroxide TS  To a volume of sodium hypochlorite TS for ammonium limit test, equivalent to 1.05 g of sodium hypochlorite (NaClO: 74.44), add 15 g of sodium hydroxide and water to make 1000 mL. Prepare before use.

Sodium hypoiodite sodium hydroxide TS  To 8 mL of iodine TS add 25 mL of water and 25 mL of sodium carbonate TS. Prepare before use.

Sodium hypochlorite TS  Prepare the solution by passing chlorine into sodium hydroxide or sodium carbonate solution, having the odor of chlorine.

Content: not less than 4.2 w/v% as sodium hypochlorite (NaClO: 74.44). Assay—Pipet 10 mL of sodium hypochlorite TS for ammonium limit test, and add water to make exactly 100 mL. Transfer exactly 10 mL of this solution to a glass-stoppered flask, add 90 mL of water, then add 2 g of potassium iodide and 6 mL of diluted acetic acid (1 in 2), stopper tightly, shake well, and allow to stand for 5 minutes in a dark place. Titrate <2.5d the liberated iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 3 mL of starch TS). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium thiosulfate VS = 3.722 mg of NaClO.

Sodium lauryl sulfate [Same as the namesake monograph]

Sodium lauryl sulfate TS  Dissolve 100 g of sodium lauryl sulfate in 900 mL of water, add 10 mL of 1 mol/L hydrochloric acid TS, and add water to make 1000 mL.

0.2% Sodium lauryl sulfate TS  Dissolve 0.1 g of sodium lauryl sulfate in 0.1 mol/L of pH 7.0 sodium phosphate buffer to make 50 mL.

Sodium metabisulfite  See sodium disulfite.

Sodium metabisulfite TS  See sodium disulfite TS.

Sodium, metallic Na  [K 8687, Sodium, Special class]

Sodium 1-methyl-1H-tetrazole-5-thiolate  See sodium 1-methyl-1H-tetrazole-5-thiolate dihydrate.

Sodium 1-methyl-1H-tetrazole-5-thiolate dihydrate  C₂H₃N₂NaS.2H₂O White, crystals or crystalline powder.

Melting point <2.60°: 90–94°C

Purity  Related substances—Dissolve 10 mg of sodium 1-methyl-1H-tetrazole-5-thiolate dihydrate in 10 mL of water, and use this solution as the sample solution. Perform the test with this solution as directed under Thin-layer Chromatography (2.68). Spot 5 μL of the sample solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of ethyl acetate, acetone, water and acetic acid (100) (10:2:1:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): any spot other than the principal spot does not appear.

Sodium molybdate  See sodium molybdate (VI) dihydrate.

Sodium molybdate (VI) dihydrate  Na₂MoO₄.2H₂O

[Sodium 2-naphthalenesulfonate  C₇H₆Na₂O₄S Pale brown, crystals or powder. Content: not less than 98.0%.

Sodium naphthoquinone sulfonate TS  Dissolve 0.25 g of sodium β-naphthoquinone sulfonate in methanol to make 100 mL.

Sodium β-naphthoquinone sulfonate  C₇H₆Na₂O₄S Yellow to orange-yellow, crystals or crystalline powder. Soluble in water, and practically insoluble in ethanol (95). Loss on drying <2.41°: Not more than 2.0% (1 g, in vacuum, 50°C).

Residue on ignition <2.44°: 26.5 – 28.0% (1 g, after drying).

Sodium nitrate  NaNO₃ [K 8562, Special class]

Sodium nitrite  NaNO₂ [K 8019, Special class]

Sodium nitrite TS  Dissolve 10 g of sodium nitrite in water to make 100 mL. Prepare before use.

Sodium nitroprusside  See sodium pentacyanonoitrosylferate (III) dihydrate.

Sodium nitroprusside TS  See sodium pentacyano-nitrosylferate (III) TS.

Sodium 1-nonanesulfonate  CH₃(CH₂)₈SO₃Na White crystalline powder. Freely soluble in water.

Loss on drying <2.41°: Not more than 1.0% (1 g, 105°C, 3 hours).

Residue on ignition <2.44°: 30 – 32% (0.5 g).

Sodium 1-octane sulfonate  CH₃(CH₂)₇SO₃Na White crystals or powder.

Residue on ignition <2.44°: 32.2 – 33.0% (1.0 g).

Sodium oxalate (standard reagent)  C₂O₄Na₂ [K 8005, Standard reagent for volumetric analysis]

Sodium pentacyanoammine ferrocate (II) n-hydrate  Na₃[Fe(CN)₅NH₃]·nH₂O A light yellow to light green-yellow crystalline powder.

Identification—(1) Dissolve 0.2 g of sodium pentacyanoammine ferrocate (II) n-hydrate in 5 mL of water, add 2 mL of sodium hydroxide solution (1 in 10), and heat: ammonia gas is evolved and a brown precipitate is produced.

(2) Dissolve 0.25 g of sodium pentacyanoammine ferro-
Sodium pentacyanotrisulfonate (III)-potassium hexacyanoferrate (III) TS

Mix an equal volume of a solution of sodium pentacyanotrisulfonate (III) dihydrate (in 50 mL) and a solution of potassium hexacyanoferrate (III) (1 in 100) and add water to make 25 mL, mix, and use after changing the color of the solution from a dark red to yellow. Prepare before use.

Sodium pentacyanotrisulfonate (III) dihydrate

\[ \text{Na}_2\text{Fe(CN)}_5\text{(NO)} \cdot 2\text{H}_2\text{O} \]

[Sodium perchlorate monohydrate] [K 8227, Special class]

\[ \text{NaClO}_3 \cdot \text{H}_2\text{O} \]

[Sodium perchlorate monohydrate] [K 8227, Special class]

[Sodium periodate] [K 8256, Special class]

\[ \text{NaIO}_4 \]

[Sodium periodate TS] Dissolve 60.0 g of sodium periodate in 120 mL of 0.05 mol/L sulfuric acid TS, and add water to make 1000 mL. If the solution is not clear, filter this through a glass-filter. Keep in a light-resistant vessel.

[Sodium peroxide] [NaO\(_2\)] [K 8231, Special class]

[Sodium p-phenol sulfonate] See sodium p-phenol sulfonate dihydrate.

Sodium p-phenol sulfonate dihydrate

C\(_6\)H\(_5\)O\(_4\)NaS\(_2\)H\(_2\)O

White to light yellow, crystals or crystalline powder, having a specific odor.

Identification

(1) To 10 mL of a solution of sodium p-phenol sulfonate (1 in 10) add 1 drop of iron (III) chloride TS: a purple color develops.

(2) Determine the absorption spectrum of a solution of sodium p-phenol sulfonate (1 in 5000) as directed under Ultraviolet-visible Spectrophotometry <\(2.24\)): it exhibits maxima between 269 nm and 273 nm and between 276 nm and 280 nm.

Purity

Clarity and color of solution—Dissolve 1.0 g of sodium p-phenol sulfonate in 25 mL of water: the solution is clear and colorless.

Content

Not less than 90.0%. Assay—Dissolve about 0.5 g of sodium p-phenol sulfonate, accurately weighed, in 50 mL of water. Transfer the solution to a chromatographic column, prepared by pouring strongly acidic ion exchange resin (H type) for column chromatography (150 to 300 \(\mu\)m in particle diameter) into a chromatographic tube about 1 cm in inside diameter and about 30 cm in height, and allow to flow. Wash the chromatographic column with water until the washing is no longer acidic, combine the washings with the above effluent solution, and titrate <\(2.50\) with 0.1 mol/L sodium hydroxide VS (indicator: 5 drops of bromocresol green-methyl red TS). Separately, dissolve 0.5 g of sodium p-phenol sulfonate, previously weighed accurately, in 50 mL of water and titrate with 0.1 mol/L sodium hydroxide VS, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 23.22 mg of C\(_6\)H\(_5\)O\(_4\)NaS\(_2\)H\(_2\)O

[Sodium phosphate] See trisodium phosphate dodecahydrate.

Sodium phosphate TS

Dissolve 5.68 g of disodium hydrogen phosphate and 6.24 g of sodium dihydrogen phosphate dihydrate in water to make 1000 mL.

0.1 mol/L Sodium phosphate buffer solution, pH 7.0

Dissolve 17.9 g of disodium hydrogen phosphate dodecahydrate in water to make 500 mL. Add to this solution to a 500 mL solution prepared by dissolving 7.8 g of sodium dihydrogen phosphate dihydrate in water until the pH becomes 7.0.

[Sodium pyruvate] Prepared for microbial test.

[Sodium salicylate] HOC\(_6\)H\(_4\)COONa [K 8397, Special class]

[Sodium salicylate-sodium hydroxide TS] Dissolve 1 g of sodium salicylate in 0.01 mol/L sodium hydroxide VS to make 100 mL.

[Sodium selenite] Na\(_2\)SeO\(_3\) A white crystalline powder.

Identification—(1) Dissolve 1 g of sodium selenite in 100 mL of water, and use this as the sample solution. To 10 mL of the sample solution add 2 mL of tin (II) chloride TS: a red precipitate is produced.

(2) The sample solution obtained in (1) responds to the Qualitative Tests <\(1.09\) (1) for sodium salt. Preserve in a light-resistant tight container.

[Sodium sulfate] See sodium sulfate monohydrate.
Sodium p-styrenesulfonate \( \text{C}_8\text{H}_8\text{NaO}_3\text{S} \) White crystals or crystalline powder. Freely soluble in water, slightly soluble in ethanol (99.5), and practically insoluble in diethyl ether.

Recrystallize from diluted ethanol (1 in 2), and dry in vacuum.

\textbf{Identification}—Determine the infrared absorption spectrum of sodium p-styrenesulfonate according to the potassium bromide disk method under Infrared Spectrophotometry \( <2.25> \); it exhibits absorption at the wave numbers of about 1236 cm\(^{-1} \), 1192 cm\(^{-1} \), 1136 cm\(^{-1} \), 1052 cm\(^{-1} \), 844 cm\(^{-1} \), and 688 cm\(^{-1} \).

\textbf{Optical rotation} \( <2.49> \) \( [\alpha]_D^10 + 40 - 50^o \) (40 mg, methanol, 20 mL, 100 mm).

\textbf{Purity}—Perform the test with 10 \( \mu \)L of a solution of sodium p-styrenesulfonate (1 in 1000) as directed in the Assay under Panipenem: Any obtrusive peaks for determination of panipenem are not observed.

\textbf{Sodium sulfate} See sodium sulfate decahydrate.

\textbf{Sodium sulfate, anhydrous} \( \text{Na}_2\text{SO}_4 \) [K 8987, Special class]

\textbf{Sodium sulfate decahydrate} \( \text{Na}_2\text{SO}_4.10\text{H}_2\text{O} \) [K 8986, Special class]

\textbf{Sodium sulfite} See sodium sulfite enneahydrate.

\textbf{Sodium sulfite enneahydrate} \( \text{Na}_2\text{S}_9\text{H}_2\text{O} \) [K 8949, Special class]

\textbf{Sodium sulfite TS} Dissolve 5 g of sodium sulfite enneahydrate in a mixture of 10 mL of water and 30 mL of glycerin. Or dissolve 5 g of sodium hydroxide in a mixture of 30 mL of water and 90 mL of glycerin, saturate a half volume of this solution with hydrogen sulfide, while cooling, and mix with the remaining half. Preserve in well-filled, light-resistant bottles. Use within 3 months.

\textbf{Sodium sulfite} See sodium sulfite heptahydrate.

\textbf{Sodium sulfite, anhydrous} \( \text{Na}_2\text{SO}_3 \) [K 8061, Sodium sulfite, Special class]

\textbf{Sodium sulfite heptahydrate} \( \text{Na}_2\text{SO}_3.7\text{H}_2\text{O} \) [K 8060, Special class]

\textbf{1 mol/L Sodium sulfite TS} Dissolve 1.26 g of anhydrous sodium sulfite in water to make 10 mL.

\textbf{Sodium-sulfite-sodium dihydrogen phosphate TS} Mix 1.5 mL of a solution dissolved 1.26 g of anhydrous sodium sulfite in 100 mL of water and 98.5 mL of a solution dissolved 1.56 g of sodium dihydrogen phosphate dihydrate in 100 mL of water. Prepare before use.

\textbf{Sodium tartrate} See sodium tartrate dihydrate.

\textbf{Sodium tartrate dihydrate} \( \text{C}_6\text{H}_4\text{Na}_2\text{O}_6.2\text{H}_2\text{O} \) [K 8540, Special class]

\textbf{Sodium toluenesulfonamide} \( \text{C}_8\text{H}_8\text{ClNNaO}_2\text{S.3H}_2\text{O} \) White. A white powder, or crystalline powder. Freely soluble in methanol, soluble in water, and sparingly soluble in ethanol (99.5).

\textbf{Identification}—Determine the infrared absorption spectrum of sodium toluenesulfonamide for thin-layer chromatography as directed in the potassium bromide disk method under Infrared Spectrophotometry \( <2.25> \); it exhibits the absorption at the wave numbers of about 2940 cm\(^{-1} \), 1600 cm\(^{-1} \), 1410 cm\(^{-1} \), 1305 cm\(^{-1} \), 1195 cm\(^{-1} \), 1080 cm\(^{-1} \), 1045 cm\(^{-1} \), 980 cm\(^{-1} \), 950 cm\(^{-1} \), 910 cm\(^{-1} \), and 860 cm\(^{-1} \).

\textbf{Optical rotation} \( <2.49> \) \( [\alpha]_D^10 + 40 - 50^o \) (40 mg, methanol, 20 mL, 100 mm).

\textbf{Purity}—Perform the test with 10 \( \mu \)L of sodium toluenesulfonamide for thin-layer chromatography in 1 mL of methanol, and use this solution as the sample solution. Pipet 0.2 mL of this solution, add methanol to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography \( <2.03> \). Perform the test with 5 \( \mu \)L each of the sample solution and standard solution as directed in the Identification under Bear Bile: the spots other than the principal spot at the RI value of about 0.2 obtained from the sample solution are not more intense than the spot from the standard solution.

\textbf{Sodium tetraborate-calcium chloride buffer solution, pH 8.0} Dissolve 0.572 g of sodium tetraborate decahydrate and 2.94 g of calcium chloride dihydrate in 800 mL of freshly boiled and cooled water, adjust the pH to 8.0 with 1 mol/L hydrochloric acid TS, and add water to make 1000 mL.

\textbf{Sodium tetraborate decahydrate} \( \text{Na}_2\text{B}_2\text{O}_5.10\text{H}_2\text{O} \) [K 8866, for pH standard solution]

\textbf{Sodium tetraborate-sulfuric acid TS} To 9.5 g of sodium tetraborate decahydrate add 1000 mL of purified sulfuric acid, and dissolve by shaking for a night.

\textbf{Sodium tetraphenylborate} \( (\text{C}_6\text{H}_5)_2\text{B} \) [K 9521]

\textbf{Sodium thioglycolate} \( \text{HSCH}_2\text{COONa} \) A white powder, having a characteristic odor.

\textbf{Identification} (1) To a solution (1 in 10) add 1 drop each of ammonia solution (28) and iron (III) chloride TS: a dark red-purple color appears.

(2) Perform the test as directed under Flame Coloration Test (1) \( <1.0> \): a yellow color appears.

\textbf{Purity} Clarity and color of solution—Dissolve 1 g in 10 mL of water: the solution is clear and colorless.

\textbf{Sodium thiosulfate} See sodium thiosulfate pentahydrate.

\textbf{Sodium thiosulfate pentahydrate} \( \text{Na}_2\text{S}_2\text{O}_3.5\text{H}_2\text{O} \) [K 8637, Special class]

\textbf{Sodium thiosulfate TS} Dissolve 26 g of sodium thiosulfate pentahydrate and 0.2 g of anhydrous sodium carbonate in freshly boiled and cooled water to make 1000 mL (0.1 mol/L).

\textbf{Sodium toluenesulfonchloramide trihydrate} \( \text{C}_8\text{H}_8\text{ClNNaO}_2\text{S.3H}_2\text{O} \) [K 8318, Sodium p-toluenesulfonchloramide trihydrate, Special class]

\textbf{Sodium toluenesulfonchloramide TS} Dissolve 1 g of sodium toluenesulfonchloramide trihydrate in water to make 100 mL. Prepare before use.

\textbf{Sodium tridecanesulfonate} \( \text{C}_{13}\text{H}_{27}\text{SO}_3\text{Na} \) White, crystalline powder or powder.

\textbf{Purity}—Perform the test as directed under Ultraviolet-visible Spectrophotometry \( <2.24> \): the absorbances at 230 nm and 245 nm are not more than the standard absorption.
0.05 and 0.01, respectively.

**Sodium 3-trimethylsilylpropanesulfonate for nuclear magnetic resonance spectroscopy**  
(CH$_3$)$_3$SiCH$_2$CH$_2$SO$_3$Na  
Prepared for nuclear magnetic resonance spectroscopy.

**Sodium 3-trimethylsilylpropionate-d$_4$ for nuclear magnetic resonance spectroscopy**  
(CH$_3$)$_3$SiCD$_2$CD$_2$COONa  
Prepared for nuclear magnetic resonance spectroscopy.

**Sodium 2,4,6-trinitrobenzenesulfonate dihydrate**  
C$_6$H$_2$N$_3$NaO$_9$S.2H$_2$O  
White or pale yellowish crystals or powder.

**Sodium tungstate**  
See sodium tungstate (VI) dihydrate.

**Sodium tungstate (VI) dihydrate**  
Na$_2$WO$_4$.2H$_2$O  
[K 8612, Special class]

**Sodium valproate for assay**  
C$_8$H$_{15}$NaO$_2$  
[Same as the monograph Sodium Valproate. When dried, it contains not less than 99.0% of sodium valproate (C$_8$H$_{15}$NaO$_2$).]

**Solid plates**  
Dilute anti-E. coli protein antibody stock solution by adding 0.2 mol/L Tris hydrochloride buffer, pH 7.4, to a concentration of about 0.02 mg/mL. Add exactly 0.1 mL of this solution to each well in the microplates, cover with plate seal, and then shake gently. Centrifuge for 2 minutes if some solution sticks to the top of the microplate or elsewhere. Dissolve 0.5 g of bovine serum albumin in 100 mL of 0.01 mol/L phosphate buffer-sodium chloride TS (pH 7.4) to make the wash solution. After leaving the microplates for 16 to 24 hours at a constant temperature of about 25°C, remove the solution in each well by aspiration, add 0.25 mL of the wash solution, shake gently, and then remove this solution by aspiration. Repeat this procedure 2 more times for each well using 0.25 mL of the wash solution. Add 0.25 mL of the block buffer solution to each well, gently shake, and let stand for 16 to 24 hours at a constant temperature of about 25°C to make solid plates. When using, remove the solution from the wells by aspiration, add 0.25 mL of the wash solution to each well, shake gently, and then remove this solution by aspiration. Repeat this procedure 2 more times using 0.25 mL of the wash solution.

**Soluble starch**  
See starch, soluble.

**Soluble starch TS**  
Triturate 1 g of soluble starch in 10 mL of cooled water, pour gradually into 90 mL of boiled water while constantly stirring, boil gently for 3 minutes, and cool. Prepare before use.

**Sorbitan sesquioleate**  
[Same as the namesake monograph]

**d-Sorbitol**  
[Same as the namesake monograph]

**d-Sorbitol for gas chromatography**  
Prepared for gas chromatography.

**Soybean-casein digest medium**  
See Sterility Test 4.06.

**Soybean oil**  
[Same as the namesake monograph]

**Soybean peptone**  
See peptone, soybean.

**Stacking gel for celmoleukin**  
In 0.5 mol/L Tris buffer solution, pH 6.8, prepare stacking the gel using ammonium persulfate and N,N',N''-tetramethyldiethylenetriamine so the acrylamide concentration is 5.2% and the sodium lauryl sulfate concentration is 0.1%.

**Stannous chloride**  
See tin (II) chloride dihydrate.

**Stannous chloride-sulfuric acid TS**  
See tin (II) chloride-sulfuric acid TS.

**Stannous chloride TS**  
See tin (II) chloride TS.

**Stannous chloride TS, acidic**  
See tin (II) chloride TS, acidic.

**Starch**  
[K 8658, Special class]

**Starch-sodium chloride TS**  
Saturate starch TS with sodium chloride. Use within 5 to 6 days.

**Starch, soluble**  
[K 8659, Special class]

**Starch TS**  
Triturate 1 g of starch with 10 mL of cold water, and pour the mixture slowly, with constant stirring, into 200 mL of boiling water. Boil the mixture until a thin, translucent fluid is obtained. Allow to settle, and use the supernatant liquid. Prepare before use.

**Stearic acid for gas chromatography**  
C$_{18}$H$_{36}$O$_2$  
[K 8855, Special class]

**Stearyl alcohol**  
[Same as the namesake monograph]

**Sterile purified water**  
[Same as the monograph Sterile Purified Water in Containers. It is not necessary to confirm if they meet all of the requirement, provided that they are confirmed to be suitable for the purpose of the relevant test.]

**Strong ammonia water**  
See ammonia solution (28).

**Strong cupric acetate TS**  
See copper (II) acetate TS, strong.

**Strong hydrogen peroxide water**  
See hydrogen peroxide (30).

**Strongly acidic ion exchange resin**  
Contains strong acid ion exchange residues. Particle diameter is about 100 μm.

**Strongly basic ion exchange resin**  
Contains strong basic ion exchange residues. Particle diameter is about 100 μm.

**Strontium TS**  
Dissolve 76.5 g of strontium chloride in 100 mL of the mobile phase and use this solution, add the mobile phase to make exactly 100 mL, and use 100 mL of this solution.

**Strontium chloride**  
See strontium chloride hexahydrate.

**Strontium chloride hexahydrate**  
SrCl$_2$.6H$_2$O  
[K 8132, Special class]

**Strychnine nitrate for assay**  
C$_7$H$_{12}$N$_2$O$_2$.HNO$_3$  
To 1 g of strychnine nitrate add 14 mL of water and about 10 mg of active carbon, heat in a water bath for 10 minutes, filter while hot, cool the filtrate quickly to form crystals, and filter the crystals. Add 8 mL of water to the crystals, dissolve by heating in a water bath, filter while hot, cool quickly, and filter the crystals formed. Repeat this procedure with 8 mL of water, and dry the crystals in a desiccator (in vacuum, silica gel) for 24 hours. Colorless or white crystals or crystalline powdered. Sparingly soluble in water, in glycerin and in chloroform, slightly soluble in ethanol (95), and practically insoluble in diethyl ether.  

**Purity**  
Related substances—Dissolve 35 mg of strychnine nitrate for assay in 100 mL of the mobile phase and use this solution as the sample solution. Pipet 2 mL of the sample solution, add the mobile phase to make exactly 100 mL, and
use this solution as the standard solution (1). Perform the test with exactly 20 \(\mu\)L each of the sample solution and standard solution (1) as directed under Liquid Chromatography <2.01> according to the following conditions. Measure each peak area of these solutions by the automatic integration method: the total area of the peaks other than strychnine from the sample solution is not larger than the peak area of strychnine from the standard solution (1).

Operating conditions
Proceed the operating conditions in the Assay under Nux Vomica except detection sensitivity and time span of measurement.

Detection sensitivity: Pipet 1 mL of the standard solution (1), add the mobile phase to make exactly 40 mL, and use this solution as the standard solution (2). Adjust the detection sensitivity so that the peak area of strychnine obtained from 20 \(\mu\)L of the standard solution (2) can be measured by the automatic integration method and the peak height of strychnine from 20 \(\mu\)L of the standard solution (1) is about 20% of the full scale.

Time span of measurement: About 3 times as long as the retention time of strychnine beginning after the solvent peak.

Loss on drying <2.4I>: not more than 0.5% (0.2 g, 105°C, 3 hours).

Content: not less than 99.0% calculated on the dried basis. Assay—Dissolve about 0.5 g of strychnine nitrate for assay, accurately weighed, in 40 mL of a mixture of acetic anhydride and acetic acid (100) (4:1), heat if necessary, cool, and titrate with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 39.74 mg of \(C_21H_22N_2O_2\cdotHNO_3\)

**Styrene** \(C_2H_4\) Colorless, clear liquid.

**Specific gravity** <2.56>: \(d: 0.902 – 0.910\)

**Purity**—Perform the test with 1 \(\mu\)L of styrene as directed under Gas Chromatography <2.02> according to the following conditions. Measure each peak area by the automatic integration method and calculate the amount of styrene by the area percentage method: it shows the purity of not less than 99%.

Operating conditions
Detector: Thermal conductivity detector.
Column: A glass column, about 3 mm in inside diameter and about 2 m in length, packed with siliceous earth (180 to 250 \(\mu\)m in particle diameter) coated with polyethylene glycol 20 M at the ratio of 10%.

Column temperature: A constant temperature of about 100°C.

Temperature of sample vaporization chamber: A constant temperature of about 150°C.

Carrier gas: Helium

Flow rate: Adjust the flow rate so that the retention time of styrene is about 10 minutes.

Time span of measurement: About twice as long as the retention time of styrene, beginning after the solvent peak.

**Styrene-maleic acid alternating copolymer partial butyl ester** A copolymer of styrene and maleic anhydride, polymerized using cumene as solvent and added 1-butanol or water to the maleic anhydride groups. Average molecular mass: about 1600. A white or pale yellowish white powder.

**Identification**—Dissolve 5 mg of the substance to be examined in sodium hydrogencarbonate solution (1 in 15) to make 10 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry <2.24> it exhibits a maximum between 256 nm and 260 nm, and a shoulder between 251 nm and 256 nm.

Absorbance <2.24> \(E_{1%}(258\text{ nm})\): 6.3 – 7.3 [5 mg calculated on the anhydrous basis, sodium hydrogencarbonate solution (1 in 15), 10 mL]

**Purity**—Proceed as directed in the Purity (3) under Zinostatin Stimalamer, with the exception of without using of (ii) Standard solution, and changing (iv) Sample solution, (v) Procedure and (vii) Determination as follows:

(iv) Sample solution Dissolve 3.0 mg of the substance to be examined in the buffer solution for sample to make 20 mL.

(v) Procedure Mount the gel in the electrophoresis apparatus. Add a mixture of 200 mL of Solution F and 2 mL of bromophenol blue solution (1 in 100,000) to the top reservoir (cathode) and 300 mL of Solution F to the lower reservoir (anode). Introduce carefully exactly 100 \(\mu\)L of the sample solution onto the surface of the gel, and allow electrophoresis at room temperature to take place with a current of 2 mA per tube as a bromophenol blue band is passing in the stacking gel and then increase the current to 4 mA per tube as the bromophenol blue band is passing in the resolving gel, and stop the current when the band reached at 5 cm from the upper end of the gel.

(vii) Determination Determine the peak area, \(A_f\), of styrene-maleic acid alternating copolymer partial butyl ester and the total area, \(A\), of the peaks other than styrene-maleic acid alternating copolymer partial butyl ester, based on the absorbance at 600 nm of the gel determined by using a densitometer. Calculate the amount of styrene-maleic acid alternating copolymer partial butyl ester by the following formula: not less than 98.0%.

Amount (%) of styrene-maleic acid alternating copolymer partial butyl ester

\[
= \frac{A_f/(A_f + A)}{100}
\]

**Water <2.4H>:** Not more than 10.0% (10 mg, coulometric titration).

**Substrate buffer for celmoleukin** Dissolve 32.4 g of tripotassium citrate monohydrate in water to make 1000 mL, and add 1 mol/L citric acid TS for buffer solution to adjust the pH to 5.5. To 100 mL of this solution add and dissolve 0.44 g of o-phenylenediamine and then 60 \(\mu\)L of hydrogen peroxide (30). Prepare at the time of use.

**Substrate TS for lysozyme hydrochloride** To a suitable amount of dried cells of Micrococcus luteus add a suitable amount of phosphate buffer solution, pH 6.2, gently shake to make a suspension, and add the substrate cells or the same buffer solution so that the absorbance of the suspension at 640 nm is about 0.65. Prepare before use.

**Substrate TS for peroxidase determination** Dissolve 0.195 mL of hydrogen peroxidase (30), 8.38 g of disodium hydrogen phosphate dodecahydrate and 1.41 g of citric acid monohydrate in water to make 300 mL. To 15 mL of this solution add 13 mg of o-phenylenediamine dihydrochloride before use.

**Substrate TS for kallidinogenase assay (1)** Dissolve an
appropriate amount of H-D-valyl-L-leucyl-L-arginine \( p \)-nitroanilide dihydrochloride in 0.1 mol/L tris buffer solution, pH 8.0 to prepare a solution containing 1 mg of H-D-valyl-L-leucyl-L-arginine \( p \)-nitroanilide dihydrochloride in 5 mL.

**Substrate TS for kallidinogenase assay (2)** Dissolve 17.7 mg of \( N \)-\( \alpha \)-benzoyl-L-arginine ethyl ester hydrochloride in 0.1 mol/L tris buffer solution, pH 8.0 to make 100 mL.

**Substrate TS for kallidinogenase assay (3)** Suspend 0.6 g of milk casein purified by the Hammerstein's method in 80 mL of 0.05 mol/L sodium hydrogen phosphate TS, and dissolve by warming at 65°C for 20 minutes. After cooling, adjust to pH 8.0 with 1 mol/L hydrochloric acid TS or sodium hydroxide TS, and add water to make exactly 100 mL. Prepare before use.

**Substrate TS for kallidinogenase assay (4)** Dissolve 25 mg of H-D-valyl-L-leucyl-L-arginine-4-nitroanilide dihydrochloride in 5 mL of the internal standard solution and the mobile phase to make 100 mL, and use these solutions as the sample solution and standard solution, respectively. Perform the test with 10 \( \mu \)L each of these solutions as directed under Liquid Chromatography 2.01 according to the following conditions, and calculate the ratios, \( Q_1 \) and \( Q_3 \), of the peak area of sulbactam to that of the internal standard.

\[
\text{Amount [mg (potency)] of sulbactam (C}_8\text{H}_{11}\text{NO}_5\text{S)} = M_S \times \frac{Q_1}{Q_3} \times 1000
\]

\( M_S \): amount [mg (potency)] of Sulbactam RS

Internal standard solution—A solution of ethyl parahydroxybenzoate in the mobile phase (7 in 1000).

**Operating conditions**
- **Detector:** Ultraviolet absorption photometer (wavelength: 220 nm)
- **Column:** A stainless steel column 3.9 mm in inside diameter and 30 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (10 \( \mu \)m in particle diameter).
- **Column temperature:** A constant temperature of about 35°C.
- **Mobile phase:** To 750 mL of 0.005 mol/L tetrabutylammonium hydroxide TS add 250 mL of acetonitrile for liquid chromatography.
- **Flow rate:** Adjust the flow rate so that the retention time of sulbactam is about 6 minutes.

**System suitability**
- **System performance:** When the procedure is run with 10 \( \mu \)L of the standard solution according to the above operating conditions, sulbactam and the internal standard are eluted in this order with the resolution between these peaks being not less than 1.5.
- **System repeatability:** When the test is repeated 6 times with 10 \( \mu \)L of the standard solution according to the above operating conditions, the relative standard deviation of the peak areas of sulbactam is not more than 2.0%.

**Sulfamic acid (standard reagent)** See amido sulfuric acid (standard reagent).

**Sulfanilamide** \( \text{H}_2\text{NC}_6\text{H}_4\text{SO}_2\text{NH}_2 \) [K 9066, Special class]

**Sulfanilamide for titration of diazotization** \( \text{H}_2\text{NC}_6\text{H}_4\text{SO}_2\text{NH}_2 \) [K 9066, For titration of diazotization]

**Sulfanilic acid** \( \text{H}_2\text{NC}_6\text{H}_4\text{SO}_3\text{H} \) [K 8586, Special class]

**Sulfathiazole** \( \text{C}_9\text{H}_9\text{N}_3\text{O}_3\text{S}_2 \) White crystalline powder.

**Melting point** 205–209°C

**Sulfathiazole for liquid chromatography** See 5-sulfosalicylic acid dihydrate.

**5-Sulfosalicylic acid dihydrate** \( \text{C}_7\text{H}_6\text{O}_6\text{S}.2\text{H}_2\text{O} \) [K 859, Special class]

**Sulfasalazine TS** Dissolve 5 g of 5-sulfosalicylic acid dihydrate in water to make 100 mL.

**Sulfur S** [K 8088, Special class]

**Sulfur dioxide** \( \text{SO}_2 \) Prepare by adding sulfuric acid dropwise to a concentrated solution of sodium bisulfite. Colorless gas, having a characteristic odor.

**Sulfuric acid** \( \text{H}_2\text{SO}_4 \) [K 895, Special class]

**Sulfuric acid, dilute** Cautiously add 5.7 mL of sulfuric acid to 10 mL of water, cool, and dilute with water to make
100 mL (10%).

**Sulfuric acid-ethanol TS** With stirring, add slowly 3 mL of sulfuric acid to 1000 mL of ethanol (99.5), and cool.

**Sulfuric acid for readily carbonizable substances** To sulfuric acid, the content of which has previously been determined by the following method, add water cautiously, and adjust the final concentration to 94.5% to 95.5% of sulfuric acid (H₂SO₄). When the concentration is changed owing to absorption of water during storage, prepare freshly.

*Assay—Weigh accurately about 2 g of sulfuric acid in a glass-stoppered flask rapidly, add 30 mL of water, cool, and titrate 0.250 M solution with 1 mol/L sodium hydroxide VS (indicator: 2 to 3 drops of bromothymol blue TS).

Each mL of 1 mol/L sodium hydroxide VS = 49.04 mg of H₂SO₄

**Sulfuric acid, fuming** H₂SO₄·nSO₃ [K 8741, Special class]

**Sulfuric acid-hexane-methanol TS** To 230 mL of a mixture of hexane and methanol (1:3) add cautiously 2 mL of sulfuric acid.

**Sulfuric acid-methanol TS** Prepare carefully by adding 60 mL of sulfuric acid to 40 mL of methanol.

**Sulfuric acid-methanol TS, 0.05 mol/L** Add gradually 3 mL of sulfuric acid to 1000 mL of methanol, while stirring, and allow to cool.

**Sulfuric acid-monobasic sodium phosphate TS** See sulfuric acid-sodium dihydrogenphosphate TS.

**Sulfuric acid, purified** Place sulfuric acid in a beaker, heat until white fumes are evolved, then heat for 3 minutes cautiously and gently. Use after cooling.

**Sulfuric acid-sodium dihydrogenphosphate TS** Add 6.8 mL of sulfuric acid to 500 mL of water, then dissolve 50 g of sodium dihydrogenphosphate dihydrate in this solution, and add water to make 1000 mL.

**Sulfuric acid-sodium hydroxide TS** With stirring add slowly 120 mL of sulfuric acid to 1000 mL of water, and cool (solution A). Dissolve 88.0 g of sodium hydroxide in 1000 mL of freshly boiled and cooled water (solution B). Mix equal volumes of solution A and solution B.

**Sulfuric acid TS** Cautiously add 1 volume of sulfuric acid to 2 volumes of water, and while warming on a water bath add dropwise potassium permanganate TS until a pale red color of the solution remains.

**0.05 mol/L sulfuric acid TS** Dilute 100 mL of 0.5 mol/L sulfuric acid TS with water to make 1000 mL.

**0.25 mol/L sulfuric acid TS** With stirring, add slowly 15 mL of sulfuric acid to 1000 mL of water, then cool.

**0.5 mol/L sulfuric acid TS** With stirring, add slowly 30 mL of sulfuric acid to 1000 mL of water, then cool.

**1 mol/L sulfuric acid TS** Add 60 mL of sulfuric acid in 1000 mL of water slowly with stirring, then allow to cool.

**2 mol/L sulfuric acid TS** To 1000 mL of water add gradually 120 mL of sulfuric acid with stirring, and cool.

**5 mol/L sulfuric acid TS** Add 300 mL of sulfuric acid in 1000 mL of water slowly with stirring, then allow to cool.

**Sulfurous acid** See sulfurous acid solution.

**Sulfurous acid solution** A clear and colorless liquid containing more than 5% of SO₂, having a pungent odor. Specific gravity: about 1.03 g/mL.

*Identification—To 1 mL of iodine TS add 20 mL of water, and add 1 mL of sulfuric acid solution: the color of the solution disappears, and this solution forms a white precipitate upon addition of 1 mL of barium chloride TS.

Preserve at a cold place.

**Sulpiride for assay** C₁₅H₂₃N₃O₄S [Same as the monograph Sulpiride. When dried, it contains not less than 99.0% of sulpiride (C₁₅H₂₃N₃O₄S).]

**Sulpyrine** See sulpyrine hydrate.

**Sulpyrine for assay** See sulpyrine hydrate for assay.

**Sulpyrine hydrate** C₁₅H₂₃N₃O₄S·H₂O [Same as the namesake monograph]

**Sulpyrine hydrate for assay** C₁₅H₂₃N₃O₄S·H₂O [Same as the monograph Sulpyrine Hydrate. Calculated on the dried basis, it contains not less than 99.0% of sulpyrine (C₁₅H₂₃N₃O₄S).]

**Suxamethonium chloride for thin-layer chromatography** See suxamethonium chloride hydrate for thin-layer chromatography.

**Suxamethonium chloride hydrate for thin-layer chromatography** C₁₄H₂₉Cl₂N₂O₄·2H₂O [Same as the monograph Suxamethonium Chloride Hydrate]

**Swertia herb** [Same as the namesake monograph]

**Swertiamarin for thin-layer chromatography** C₁₆H₂₂O₁₀ White, practically tasteless powder. Melting point <2.60: 113 – 114°C

**Purity** Related substances—Dissolve 2.0 mg of swertiamarin for thin-layer chromatography in exactly 1 mL of ethanol (95), and perform the test with 20 μL of this solution as directed in the Identification under Swertia Herb: any spot other than the principal spot at the Rf value of about 0.5 does not appear.

**Synthetic zeolite for drying** A mixture of 6(Na₂O)·6(Al₂O₃)·12(SiO₂) and 6(K₂O)·6(Al₂O₃)·12(SiO₂) prepared for drying. Usually, use the spherically molded form, 2 mm in diameter, prepared by adding a binder. White to grayish white, or color transition by adsorbing water. Average fine pore diameter is about 0.3 nm, and the surface area is 500 to 700 m² per g. Loss on ignition <2.45: not more than 2.0% [2 g, 550 – 600°C, 4 hours, allow to stand in a desiccator (phosphorus (V) oxide).]

**Talc** [Same as the namesake monograph]

**Tamsulosin hydrochloride** C₂₀H₂₈N₂O₅S·HCl [Same as the namesake monograph]

**Tamsulosin hydrochloride for assay** C₂₀H₂₈N₂O₅S·HCl [Same as the monograph Tamsulosin Hydrochloride. When dried, it contains not less than 99.0% of tamsulosin hydrochloride (C₂₀H₂₈N₂O₅S·HCl).]

**Tannic acid** [Same as the namesake monograph]
Tannic acid TS Dissolve 1 g of tannic acid in 1 mL of ethanol (95), and add water to make 10 mL. Prepare before use.

Tartaric acid See L-tartaric acid.

L-Tartaric acid C₄H₆O₆ [K 8532, l(+)-Tartaric acid, Special class].

Tartrate buffer solution, pH 3.0 Dissolve 1.5 g of L-tartaric acid and 2.3 g of sodium tartarate dihydrate in water to make 1000 mL.

Taurine H₂NCH₂CH₂SO₃H White crystals or crystalline powder.

Contents: not less than 95.0%. Assay—Weigh accurately about 0.2 g, dissolve in 50 mL of water, add 5 mL of formaldehyde solution, and titrate with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of phenolphthalein TS). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 12.52 mg of C₂H₇NO₃S

Temocapril hydrochloride for assay C₂₂H₃₁O₄S₂.HCl [Same as the monograph Temocapril Hydrochloride. It contains not less than 99.5% of temocapril hydrochloride (C₂₂H₃₁O₄S₂.HCl: 513.07), calculated on the anhydrous basis.]

Terbinafine hydrochloride for assay C₂₁H₂₅N.HCl [Same as the monograph Terbinafine Hydrochloride]  

Terephthalic acid C₁₂H₈O₄ White crystals or crystalline powder. Slightly soluble in ethanol (95), and practically insoluble in water and ether.  

Residue on ignition <2.44%: not more than 0.3% (1 g).  

Content: not less than 95.0%. Assay—Weigh accurately about 2 g of terephthalic acid, dissolve in exactly 50 mL of 1 mol/L hydrochloric acid VS, and titrate with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of phenolphthalein TS). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 83.07 mg of C₁₂H₈O₄

Terphenyl C₁₈H₁₄ White crystalline powder. 

Identification—Determine the absorption spectrum of a solution of terphenyl in methanol (1 in 250,000) as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.257: it exhibits the absorption at the wave numbers of about 3530 cm⁻¹, 3380 cm⁻¹, 1612 cm⁻¹, 1233 cm⁻¹, 1067 cm⁻¹ and 1056 cm⁻¹.

Testosterone propionate C₁₇H₂₃O₃ [Same as the name-sake monograph]

Tetra-bromophenolphthalein ethyl ester potassium salt C₂₅H₂₃O₄Br₄K [K 9042, Special class]

Tetra-bromophenolphthalein ethyl ester TS Dissolve 0.1 g of tetrabromophenolphthalein ethyl ester potassium salt in acetic acid (100) to make 100 mL. Prepare before use.

Tetra-n-butylammonium bromide [CH₃(CH₂)₃N]Br White, crystals or crystalline powder, having a slight, characteristic odor.

Melting point 2.60°: 101 – 105°C

Purity Clarity and color of solution—Dissolve 1.0 g of tetra-n-butylammonium bromide in 20 mL of water: the solution is clear and colorless.

Content: not less than 98.0%. Assay—Dissolve about 0.5 g of tetra-n-butylammonium bromide, accurately weighed, in 50 mL of water, add 5 mL of dilute nitric acid, and titrate with 0.1 mol/L silver nitrate VS while strongly shaking (potentiometric titration). Perform a blank determination and make any necessary correction.

Each mL of 0.1 mol/L silver nitrate VS = 27.79 mg of C₁₃H₂₅NBr

Tetra-n-butylammonium chloride C₁₅H₃₂ClN White crystals, and it is deliquescent.

Water <2.48°: not more than 6.0% (0.1 g).

Content: not less than 95.0%, calculated on the anhydrous basis. Assay—Weigh accurately about 0.25 g of tetra-n-butylammonium chloride, dissolve in 50 mL of water, and titrate with 0.1 mol/L silver nitrate VS (potentiometric titration).

Each mL of 0.1 mol/L silver nitrate VS = 27.79 mg of C₁₅H₃₂ClN

Tetrabutylammonium hydrogensulfate C₁₃H₃₇NO₄S White crystalline powder.

Content: not less than 98.0%. Assay—Weigh accurately about 0.7 g of tetrabutylammonium hydrogensulfate, dissolve in 100 mL of freshly boiled and cooled water, and titrate with 0.1 mol/L sodium hydroxide VS (indicator: 3 drops of bromocresol green-methyl red TS).

Each mL of 0.1 mol/L sodium hydroxide VS = 33.95 mg of C₁₃H₃₇NO₄S

40% Tetrabutylammonium hydroxide TS A solution containing 40 g/dL of tetrabutylammonium hydroxide [(C₄H₉)₄NOH: 259.47].

Content: 36 – 44 g/dL. Assay—Pipet 10 mL of 40% tetrabutylammonium hydroxide TS, and titrate with 0.1 mol/L hydrochloric acid VS (indicator: 3 drops of methyl red TS).

Each mL of 1 mol/L hydrochloric acid VS = 259.5 mg of C₄H₉NO

0.005 mol/L Tetrabutylammonium hydroxide TS To 10 mL of tetrabutylammonium hydroxide TS add 700 mL of
water, adjust to pH 4.0 with diluted phosphoric acid (1 in 10), and add water to make 1000 mL.

Tetraethylammonium hydroxide-methanol TS Methanol solution containing 25 g/dL of tetraethylammonium hydroxide [(C2H5)4NOH: 259.47]. Colorless to pale yellow solution, having an ammonium-like odor.

Content: 22.5 – 27.5 g/dL. Assay—Pipet 15 mL of tetraethylammonium hydroxide-methanol TS and titrate <2.50< with 1 mol/L hydrochloric acid VS (indicator: 3 drops of methyl red TS).

Each mL of 1 mol/L hydrochloric acid VS

\[ = 259.5 \text{ mg of } (C_2H_5)_4NOH \]

10% Tetraethylammonium hydroxide-methanol TS A methanol solution containing 10 g/dL of tetraethylammonium hydroxide [(C2H5)4NOH: 259.47].

Content: 9.0 – 11.0 g/dL. Assay—Pipet 2 mL of 10% tetraethylammonium hydroxide-methanol TS, transfer to a glass-stoppered flask containing 20 mL of water, and titrate <2.50< with 0.1 mol/L hydrochloric acid VS (indicator: 3 drops of methyl red TS).

Each mL of 0.1 mol/L hydrochloric acid VS

\[ = 25.95 \text{ mg of } (C_2H_5)_4NOH \]

Tetraethylammonium hydroxide TS A solution containing 13 g/dL of tetraethylammonium hydroxide [(C2H5)4NOH: 259.47].

Content: 11.7 – 14.3 g/dL. Assay—Pipet a quantity, equivalent to about 0.3 g of tetraethylammonium hydroxide [(C2H5)4NOH], transfer to a glass-stoppered flask containing 15 mL of water, accurately weighed, and titrate <2.50< with 0.1 mol/L hydrochloric acid VS (indicator: 3 drops of methyl red TS).

Each mL of 0.1 mol/L hydrochloric acid VS

\[ = 25.95 \text{ mg of } (C_2H_5)_4NOH \]

Tetraethylammonium phosphate (C2H5)4NH2PO4 White powder. It is soluble in water.

Content: not less than 97.0%. Assay—Weigh accurately about 1.5 g of tetraethylammonium phosphate, dissolve in 80 mL of water, and titrate <2.50< with 0.5 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.5 mol/L sodium hydroxide VS

\[ = 169.7 \text{ mg of } (C_2H_5)_4NH_2PO_4 \]

Tetracycline C22H24N2O8 Yellow to dark yellow, crystals or crystalline powder. Sparingly soluble in ethanol, and very slightly soluble in water.

Content: it contains not less than 870 µg (potency) per mg. Assay—Proceed as directed in the Assay under Tetracycline Hydrochloride. However, use the following formula.

\[ \text{Amount (µg (potency)) of tetracycline } (C_{22}H_{24}N_2O_8) = M_s \times \left( A_s / A_A \right) \times 1000 \]

\[ M_s: \text{ Amount [mg (potency)] of Tetracycline Hydrochloride RS} \]

Tetracycline Hydrochloride C22H24N2O8.HCl Yellow, crystals or crystalline powder.

Purity Related substances—Dissolve 20 mg of tetracycline hydrochloride in 25 mL of 0.01 mol/L hydrochloric acid TS, and use this solution as the sample solution. Proceed the test with 20 µL of the sample solution as directed in the Purity (2) under Oxytetracycline Hydrochloride, determine each peak area by the automatic integration method, and calculate the amounts of them by the area percentage method: the total amount of the peaks other than tetracycline is not more than 10%.

Tetradecyl trimethylammonium bromide CH3(CH2)13N(CH3)3Br A white powder.

Purity Clarity and color of solution—Dissolve 1.0 g in 20 mL of water: the solution is clear and colorless.

Content: not less than 98.0%. Assay—Weigh accurately about 0.5 g of tetradecyl trimethylammonium bromide, dissolve in 100 mL of water, add 5 mL of a mixture of water and nitric acid (2:1), and titrate <2.50< with 0.1 mol/L silver nitrate VS (potentiometric titration). Perform a blank test in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L silver nitrate VS

\[ = 33.64 \text{ mg of } C_{14}H_{33}NO \]

Tetraethylammonium hydroxide TS A solution containing 10% of tetraethylammonium hydroxide [C2H5)4NOH: 147.26]. A clear, colorless liquid, having a strong ammonia odor. It is a strong base and easily absorbs carbon dioxide from the air.

Content: 10.0 – 11.0% Assay—Weigh accurately about 3 g in a glass-stoppered flask containing 15 mL of water, and titrate <2.50< with 0.1 mol/L hydrochloric acid VS (indicator: 3 drops of methyl red TS). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L hydrochloric acid VS

\[ = 14.73 \text{ mg of } C_2H_5NO \]

Tetra-n-heptylammonium bromide [CH(CH2)3]4NBr White, crystals or crystalline powder, having a slight, characteristic odor.

Melting point <2.60>: 87 – 89°C

Content: not less than 98.0%. Assay—Dissolve about 0.5 g of tetra-n-heptylammonium bromide, accurately weighed, in 50 mL of diluted acetonitrile (3 in 5), and 5 mL of dilute nitric acid, and titrate <2.50< with 0.1 mol/L silver nitrate VS while strongly shaking (potentiometric titration). Perform a blank determination and make any necessary correction.

Each mL of 0.1 mol/L silver nitrate VS

\[ = 49.07 \text{ mg of } C_{14}H_{29}NO \]

Tetrahydrofuran CH3(CH2)2CH2O [K 9705, Special class]

Tetrahydrofuran for gas chromatography Use tetrahydrofuran prepared by distilling with iron (II) sulfate heptahydrate.

Storage—Preserve in containers, in which the air has been displaced by nitrogen, in a dark, cold place.

Tetrahydrofuran for liquid chromatography C2H4O Clear and colorless liquid.

Refractive index <2.45>: nD20: 1.406 – 1.409

Density <2.50< 0.884 – 0.889 g/mL (20°C)

Purity Ultraviolet absorbing substances—Determine the absorption spectrum of tetrahydrofuran for liquid chromatography as directed under Ultraviolet-visible Spectrophotometry <2.24>, using water as the blank: the absorbences at
240 nm, 254 nm, 280 nm, 290 nm, and between 300 nm and 400 nm are not more than 0.35, 0.20, 0.05, 0.02 and 0.01, respectively.

Peroxide—Perform the test according to the method described in JIS K 9705: not more than 0.01%.

Tetrahydroxyquinone C₈H₈O₄ Dark blue crystals. Its color changes to yellow on exposure to light. Soluble in ethanol (95) and sparingly soluble in water.

Tetrahydroxyquinone indicator Mix 1 g of tetrahydroxyquinone with 100 g of sucrose homogeneously.

Tetrahydroxypropylenediamine for gas chromatography Prepared for gas chromatography.

Tetramethylammonium hydroxide (CH₃)₄NOH Ordinarily, available as an approximately 10% aqueous solution, which is clear and colorless, and has a strong ammonia-like odor. Tetramethylammonium hydroxide is a stronger base than ammonia, and rapidly absorbs carbon dioxide from the air. Use a 10% aqueous solution.

Purity Ammonia and other amines—Weigh accurately a quantity of the solution, corresponding to about 0.3 g of tetramethylammonium hydroxide [(CH₃)₄NOH], in a weighing bottle already containing 5 mL of water. Add a slight excess of 1 mol/L hydrochloric acid TS (about 4 mL), and evaporate on a water bath to dryness. The mass of the residue (tetramethylammonium chloride), dried at 105°C for 2 hours and multiplied by 0.8317, represents the quantity of tetramethylammonium hydroxide [(CH₃)₄NOH], and corresponds to ±0.2% of that found in the Assay.

Residue on evaporation: not more than 0.02% (5 mL, 105°C, 1 hour).

Content: not less than 98% of the labeled amount.

Assay—Accurately weigh a glass-stoppered flask containing about 15 mL of water. Add a quantity of the solution, equivalent to about 0.2 g of tetramethylammonium hydroxide [(CH₃)₄NOH], weigh again, and titrate <2.50 with 0.1 mol/L hydrochloric acid VS (indicator: methyl red TS).

Each mL of 0.1 mol/L hydrochloric acid VS = 9.115 mg of C₄H₇NO

Tetramethylammonium hydroxide-methanol TS A methanol solution containing of 10 g/dL of tetramethylammonium hydroxide [(CH₃)₄NOH]; 91.15%

Content: 9.0 – 11.0 g/dL. Assay—Pipet 2 mL of tetramethylammonium hydroxide-methanol TS, transfer to a glass-stoppered flask containing 20 mL of water, and titrate <2.50 with 0.1 mol/L hydrochloric acid VS (indicator: bromocresol green-methyl red TS).

Each mL of 0.1 mol/L hydrochloric acid VS = 9.115 mg of C₄H₇NO

Tetramethylammonium hydroxide TS Pipet 15 mL of tetramethylammonium hydroxide, and add dehydrated ethanol (99.5) to make exactly 100 mL.

Tetramethylammonium hydroxide TS, pH 5.5 To 10 mL of tetramethylammonium hydroxide add 990 mL of water, and adjust the pH to 5.5 with diluted phosphoric acid (1 in 10).

3,3',5,5'-Tetramethylbenzidine dihydrochloride dihydrate C₁₆H₂₂Cl₂N₂·H₂O White to slightly reddish-white crystalline powder.

N,N',N',N'-Tetramethylethlenediamine (CH₃)₂NCH₂CH₂N(CH₃)₂ Pale yellow clear liquid.

Specific gravity 2.560 ± 0.020; 0.774 – 0.799

Content: not less than 99.0%.

Tetramethylsilane for nuclear magnetic resonance spectroscopy (CH₃)₄Si Prepared for nuclear magnetic resonance spectroscopy.

Tetra-n-pentylammonium bromide [CH₃(CH₂)₄NH]Br White, crystals or crystalline powder. It is hygroscopic.

Melting point <2.60°C: 100 – 101°C

Tetraphenylboron potassium TS Add 1 mL of acetic acid (31) to a solution of potassium biphthalate (1 in 500), then to this solution add 20 mL of a solution of tetraphenylboron sodium (7 in 1000), shake well, and allow to stand for 1 hour. Collect the produced precipitate on filter paper, and wash it with water. To 1/3 quantity of the precipitate add 100 mL of water, warm, with shaking, at about 50°C for 5 minutes, cool quickly, allow to stand for 2 hours with occasional shaking, and filter, discarding the first 30 mL of the filtrate.

Tetraphenylboron sodium See sodium tetraphenylborate.

Tetra-n-propylammonium bromide [CH₃CH₂CH₂NH]Br White, crystals or crystalline powder.

Purity Clarity and color of solution—Dissolve 1.0 g of tetra-n-propylammonium bromide in 20 mL of water: the solution is clear and colorless.

Content: not less than 98.0%. Assay—Weigh accurately about 0.4 g of tetra-n-propylammonium bromide, dissolve in 50 mL of water, add 5 mL of dilute nitric acid, and titrate <2.50 with 0.1 mol/L silver nitrate VS while shaking strongly (potentiometric titration).

Each mL of 0.1 mol/L silver nitrate VS = 26.63 mg of C₃H₅Br

Theophylline C₇H₈N₄O₂ White powder. Slightly soluble in water.

Melting point <2.60°C: 269 – 274°C

Purity Caffeine, theobromine or paraxanthine—To 0.20 g of theophylline add 5 mL of potassium hydroxide TS or 5 mL of ammonia TS: each solution is clear.

Loss on drying <2.41%: not more than 0.5% (1 g, 105°C, 4 hours).

Content: not less than 99.0%. Assay—Weigh accurately about 0.25 g of theophylline, previously dried, dissolve it in 40 mL of N,N-dimethylformamide, and titrate <2.50 with 0.1 mol/L sodium methoxide VS (indicator: 3 drops of thymol blue-N,N-dimethylformamide TS). Perform a blank determination and make any necessary correction.

Each mL of 0.1 mol/L sodium methoxide VS = 18.02 mg of C₇H₈N₄O₂

Theophylline for assay C₇H₈N₄O₂ [Same as the monograph Theophylline meeting the following additional specifications.]

Purity Related substances—Dissolve 50 mg of theophylline for assay in water to make 100 mL, and use this solution as the sample solution. Pipet 1 mL of this solution, add water to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 20 µL of the
sample solution and standard solution as directed under Liquid Chromatography. Determine each peak from both solutions by the automatic integration method: the total area of peaks other than the peak of theophylline obtained from the sample solution is not larger than the peak area of theophylline from the standard solution.

Operating conditions
Detector: An ultraviolet absorption photometer (wavelength: 270 nm).
Column: A stainless steel column 6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Mobile phase: A mixture of diluted acetic acid (100) (1 in 100) and methanol (4:1).
Flow rate: Adjust the flow rate so that the retention time of theophylline is about 10 minutes.
Time span of measurement: About 3 times as long as the retention time of theophylline.
System suitability
Test for required detectability: Pipet 5 mL of the standard solution, and add water to make exactly 25 mL. Confirm that the peak area of theophylline obtained from 20 μL of this solution is equivalent to 15 to 25% of that of theophylline from 20 μL of the standard solution.
System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of theophylline are not less than 3000 and not more than 1.5, respectively.
System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of theophylline is not more than 3.0%.

Thiamine nitrate C₁₂H₁₇N₅O₄S [Same as the namesake monograph]
Thianthol [Same as the monograph Thianthol. Proceed as directed in the Identification (3) under Sulfur, Salicylic Acid and Thianthol Ointment: any spot other than the principal spot does not appear.]

3-Thienylethylpenicillin sodium C₁₄H₁₅N₂O₂S₂ White to pale yellowish white powder. Very soluble in water, freely soluble in methanol, and sparingly soluble in ethanol (95%).

Optical rotation \(\left< 2.49^\circ \right> [\alpha]^{20}_D + 265 + 290^\circ\) (0.5 g calculated on the anhydrous bases, water, 50 mL, 100 mm).

Water \(\left< 2.48^\circ\right>:\) Not more than 10.0% (0.2 g, volumetric titration, direct titration).

Content: not less than 90% calculated on the anhydrous basis. Assay—Weigh accurately about 0.1 g of 3-thienylethylpenicillin sodium, dissolve in 35 mL of water, add 0.75 mL of 0.1 mol/L hydrochloric acid TS, and adjust to pH 8.5 with 0.1 mol/L sodium hydroxide TS. To this solution add 2 mL of a penicillinsae solution prepared by dissolving penicillinsae, equivalent to 513,000 Levy units, in 25 mL of water and neutralizing with dilute sodium hydroxide TS until a pale red color appears with 1 drop of a solution of phenolphthalein in ethanol (95) (1 in 1000) as indicator, and allow to stand at 25°C for 5 minutes. Titrate \(\left< 2.50^\circ\right>\) this solution with 0.1 mol/L sodium hydroxide VS until the solution reaches to pH 8.5 (potentiometric titration). Use the water freshly boiled and cooled.

Each mL of 0.1 mol/L sodium hydroxide VS = 36.24 mg of C₁₄H₁₅N₂NaO₄S₂

Thimerosal C₁₂H₁₅N₂NaO₂ S White or yellowish crystalline powder. Freely soluble in water.

Melting point \(\left< 2.6^\circ\right>: 107 – 114°C.

Thioacetamide C₃H₇NS A white crystalline powder or colorless crystals, having a characteristic odor. Freely soluble in water and in ethanol (99.5). Melting point: 112 – 115°C

Thioacetamide-alkaline glycerin TS To 0.2 mL of a solution of thioacetamide (1 in 25) add 1 mL of alkaline glycerin TS, and heat for 20 seconds in a water bath. Prepare before use.

Thioacetamide TS To 0.2 mL of a solution of thioacetamide (1 in 25) add 1 mL of a mixture of 15 mL of sodium hydroxide TS, 5 mL of water and 20 mL of 85% glycerin, and heat in a water bath for 20 seconds. Prepare before use.

Thiodiglycol S(CH₂CH₂OH)₂ [β-Thiodiglycol for amino acid autoanalysis] Colorless or pale yellow, clear liquid.

Specific gravity \(\left< 2.56^\circ\right> d_{0}^{20}: 1.180 – 1.190\)

Water \(\left< 2.48^\circ\right>:\) not more than 0.7%.

Thioglycolate medium I for sterility test See fluid thioglycolate medium.

Thioglycolate medium II for sterility test See alternative thioglycolate medium.

Thioglycolic acid See mercapto acetic acid.

Thionyl chloride SOCl₂ A colorless or light yellow, clear liquid, having a pungent odor.

Specific gravity \(\left< 2.56^\circ\right> d_{0}^{20}:\) about 1.65 (Method 3)

Content: not less than 95.0%. Assay—Weigh accurately 0.1 g of thionyl chloride in a weighing bottle, put the bottle in a glass-stoppered conical flask containing 50 mL of water cooled to about 5°C, stopper immediately, dissolve the sample thoroughly, and transfer the solution to a 200-mL beaker. Wash the conical flask and the weighing bottle in it with 30 mL of water, and combine the washings and the solution in the beaker. Add 1 drop of an aqueous solution of polyvinyl alcohol (100 g/L), and titrate \(\left< 2.50^\circ\right>\) with 0.1 mol/L silver nitrate VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L silver nitrate VS = 5.949 mg of SOCl₂

Thiopental for assay C₃H₇N₂O₃S₄ Dissolve 10 g of Thiopental Sodium in 300 mL of water. To this solution add slowly 50 mL of dilute hydrochloric acid with stirring. Take the produced crystals by filtration, wash with water until the filtrate indicates no reaction to chloride, and air-dry. Add diluted ethanol (99.5) (3 in 5), dissolve by heating in a water bath, allow to stand, and take the produced crystals by filtration. Air-dry the crystals in air, and dry again at 105°C for 4 hours. White, odorless crystals.

Melting point \(\left< 2.6^\circ\right>: 159 – 162°C\)
Purity (1) Clarity and color of solution—Dissolve 1.0 g of thioptenal for assay in dehydrated ethanol: the solution is clear and light yellow.

(2) Related substances—Dissolve 0.05 g of thioptenal for assay in 15 mL of acetonitrile, add water to make 50 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase in the Purity (4) under Thiopental Sodium to make exactly 200 mL, and use this solution as the standard solution. Proceed as directed in Purity (4) under Thiopental Sodium.

Loss on drying (2.47): not more than 0.20% (1 g, 105°C, 3 hours).

Content: not less than 99.0%. Assay—Weigh accurately about 0.35 g of thioptenal for assay, previously dried, dissolve in 5 mL of dehydrated ethanol and 50 mL of chloroform, and titrate with 0.1 mol/L potassium hydroxide-ethanol VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L potassium hydroxide-ethanol VS = 24.23 mg of \( \text{C}_{11} \text{H}_{18} \text{N}_{2} \text{O}_{2} \)S

Thiopental sodium \( \text{C}_{11} \text{H}_{18} \text{N}_{2} \text{NaO}_{2} \)S [Same as the namesake monograph]

Thiosemicarbazide \( \text{H}_{2}\text{NCSHNH}_{2} \) White crystals or crystalline powder.

Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method as directed under Infrared Spectrophotometry (2.25): it exhibits absorption at the wave numbers of about 3370 cm\(^{-1}\), 3180 cm\(^{-1}\), 1648 cm\(^{-1}\), 1622 cm\(^{-1}\), 1535 cm\(^{-1}\), 1288 cm\(^{-1}\), 1167 cm\(^{-1}\), 1003 cm\(^{-1}\), and 803 cm\(^{-1}\).

Thiourea \( \text{H}_{2}\text{NCSNH}_{2} \) [K 8635, Special class]

Thiourea TS Dissolve 10 g of thiourea in water to make 100 mL.

L-Threonine \( \text{C}_{4}\text{H}_{9}\text{NO}_{3} \) [Same as the namesake monograph]

Threoprocaterol hydrochloride \( \text{C}_{10}\text{H}_{22}\text{N}_{2}\text{O}_{5}\text{HCl} \) To procaterol hydrochloride add 10 volumes of 3 mol/L hydrochloric acid TS, heat, and reflux for 3 hours. After cooling, neutralize (pH 8.5) with sodium hydroxide TS, and collect the crystals produced. Suspend the crystals in water, dissolve by acidifying the solution at pH 1 to 2 with addition of hydrochloric acid, neutralize (pH 8.5) by adding sodium hydroxide TS, and separate the crystals produced. Suspend the crystals in 2-propanol, and acidify the solution at pH 1 to 2 by adding hydrochloric acid. The crystals are dissolved and reproduced. Collect the crystals, dry at about 60°C while passing air. White to pale yellowish white, odorless crystals or crystalline powder. Melting point: about 207°C (with decomposition).

Purity—Dissolve 0.10 g of threoprocaterol hydrochloride in 100 mL of diluted methanol (1 in 2), and use this solution as the sample solution. Perform the test with 2 \( \mu \)L of the sample solution as directed under Liquid Chromatography according to the operating conditions in the Purity (3) under Procaterol Hydrochloride Hydrate. Measure each peak area by the automatic integration method, and calculate the amount of threoprocaterol by the area percentage method: it shows the purity of not less than 95.0%. Adjust the detection sensitivity so that the peak height of threoprocaterol obtained from 2 \( \mu \)L of the solution prepared by diluting 5.0 mL of the sample solution with diluted methanol (1 in 2) to make 100 mL, is 5 to 10% of the full scale, and the time span of measurement is about twice as long as the retention time of threoprocaterol beginning after the peak of solvent.

Thrombin [Same as the namesake monograph]

Thymine \( \text{C}_{5}\text{H}_{6}\text{N}_{2}\text{O}_{2} \) Occurs as a white powder.

Purity—Dissolve 10 mg of the substance to be examined in 100 mL of methanol, add the mobile phase to make exactly 250 mL, and use this solution as the sample solution. Pipet 5 mL of this solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Pipet 10 \( \mu \)L each of these solutions and perform the test as directed in the Purity (3) under Zudivudine. Determine the area of each peak in the sample and standard solutions by the automatic integration method: the total area of peaks other than thymine from the sample solution is not larger than that from the standard solution. However, the time span of measurement is about 10 times the retention time of thymine, beginning after the solvent peak.

Thymol \( \text{C}_{8}\text{H}_{8}\text{O} \)Occurs

Thymol blue \( \text{C}_{27}\text{H}_{30}\text{O}_{5}\text{S} \) [K 8643, Special class]

Thymol blue-N,N-dimethylformamide TS Dissolve 0.1 g of thymol blue in 100 mL of N,N-dimethylformamide.

Thymol blue-dioxane TS Dissolve 0.05 g of thymol blue in 100 mL of 1,4-dioxane, and filter if necessary. Prepare before use.

Thymol blue TS Dissolve 0.1 g of thymol blue in 100 mL of ethanol (95), and filter if necessary.

Thymol blue TS, dilute Dissolve 0.05 g of thymol blue in 100 mL of ethanol (99.5), and filter if necessary. Prepare before use.

Thymol for assay [Same as the monograph Thymol. It contains not less than 99.0% of thymol (\( \text{C}_{10}\text{H}_{10}\text{O} \).)]

Thymol for spraying test solution \( \text{C}_{9}\text{H}_{10}\text{O} \) White crystals or crystalline powder, having an aromatic odor. Very soluble in methanol and in ethanol (99.5), and practically insoluble in water.

Identification—Determine the infrared absorption spectrum as directed in the potassium bromide disk method under Infrared Spectrophotometry (2.25): it exhibits absorp-
Thymolphthalein C_{2}H_{18}N_{2}O_{4} \ [K \ 8642, \ Special \ class]

Thymolphthalein TS Dissolve 0.1 g of thymolphthalein in 100 mL of ethanol (95), and filter if necessary.

Thymol-sulfuric acid-methanol TS for spraying Dissolve 1.5 g of thymol for spraying test solution in 100 mL of methanol, and add 5.7 mL of sulfuric acid.

Tiaramide hydrochloride for assay C_{1}2H_{2}5CIN_{2}O_{4}.HCl [Same as the monograph Tiaramide Hydrochloride. When dried, it contains not less than 99.0% of tiaramide hydrochloride (C_{1}2H_{2}5CIN_{2}O_{4}.HCl).]

Tiapride hydrochloride for assay C_{1}5H_{17}N_{2}O_{4}.HCl [Same as the monograph Tiapride Hydrochloride]

Tin Sn [K 8580, Special class]

Tin (II) chloride dihydrate SnCl_{2}.2H_{2}O [K 8136, Special class]

Tin (II) chloride-hydrochloric acid TS To 20 g of tin add 85 mL of hydrochloric acid, heat until hydrogen gas no longer are evolved, and allow to cool. Mix 1 volume of this solution and 10 volume of dilute hydrochloric acid. Prepare before use.

Tin (II) chloride-sulfuric acid TS Dissolve 10 g of tin (II) chloride dihydrate in diluted sulfuric acid (3 in 200) to make 100 mL.

Tin (II) chloride TS Dissolve 1.5 g of Tin (II) chloride hydrate in 10 mL of water containing a small amount of hydrochloric acid. Preserve in glass-stoppered bottles in which a fragment of tin has been placed. Use within 1 month.

Tin (II) chloride TS, acidic Dissolve 8 g of Tin (II) chloride dihydrate in 500 mL of hydrochloric acid. Preserve in glass-stoppered bottles. Use within 3 months.

Tipepidine hibenzate for assay C_{1}2H_{17}NS_{2}.C_{1}3H_{16}O_{4} [Same as the monograph Tipepidine Hibenzate. When dried, it contains not less than 99.0% of C_{1}2H_{17}NS_{2}.C_{1}3H_{16}O_{4}]

Titanium dioxide See titanium (IV) oxide.

Titanium dioxide TS See titanium (IV) oxide TS.

Titanium (III) chloride (20) TiCl_{3} [K 8401, Titanium (III) chloride solution, Special class] Store in light-resistant, glass-stoppered containers.

Titanium (III) chloride-sulfuric acid TS Mix carefully 20 mL of titanium (III) chloride TS and 13 mL of sulfuric acid, add carefully hydrogen peroxide (30) in small portions until a yellow color develops, and heat until white fumes evolve. After cooling, add water, heat again in the same manner, repeat this procedure until the solution is colorless, and add water to make 100 mL.

Titanium (III) chloride TS To titanium (III) chloride (20) add dilute hydrochloric acid to obtain a solution containing 15 g/dL of titanium (III) chloride (TiCl_{3}). Prepare before use.

Content: 14.0 – 16.0 g/dL. Assay—To exactly 2 mL of titanium (III) chloride add 200 mL of water and 5 mL of a hydrochloric acid solution (2 in 3), and titrate <2.50 with 0.1 mol/L ferric ammonium sulfate VS under carbon dioxide until a slight red color develops in the solution (indicator: 5 mL of ammonium thiocyanate TS).

Each mL of 0.1 mol/L ferric ammonium sulfate VS = 15.42 mg of TiCl_{3}

Titanium (IV) oxide TiO_{2} [K 8703, Special class]

Titanium (IV) oxide TS To 100 mL of sulfuric acid add 0.1 g of titanium (IV) oxide, and dissolve by gradually heating on a flame with occasional gentle shaking.

Titanium trichloride See titanium (III) chloride.

Titanium trichloride-sulfuric acid TS See titanium (III) chloride-sulfuric acid TS.

Titanium trichloride TS See titanium (III) chloride TS.

Titanium yellow C_{2}8H_{19}N_{2}O_{4}.S_{4} A dark yellow to dark yellow-brown powder or masses.

Identification—Determine the infrared absorption spectrum of titanium yellow, previously dried at 105°C for 4 hours, as directed in the potassium bromide disk method as directed under Infrared Spectrophotometry (2.25); it exhibits its absorption at the wave numbers of about 1603 cm\(^{-1}\), 1467 cm\(^{-1}\), 1394 cm\(^{-1}\), 1306 cm\(^{-1}\), 1040 cm\(^{-1}\), 988 cm\(^{-1}\), 820 cm\(^{-1}\) and 644 cm\(^{-1}\).

Preserve in a light-resistant tight container.

Tocopherol C_{15}H_{17}O_2 [Same as the namesake monograph]

Tocopherol acetate C_{3}1H_{52}O_3 [Same as the namesake monograph]

Tocopherol calcium succinate C_{6}6H_{10}6CaO_{10} [Same as the namesake monograph]

Tocopherol succinate C_{1}2H_{14}O_5 Wet 0.5 g of tocopherol calcium succinate with 5 mL of acetic acid (100), add 10 mL of toluene, and warm at 70°C for 30 minutes with occasional shaking. After cooling, add 30 mL of water, shake thoroughly, and allow to stand. Remove the water layer, wash the toluene layer with several 30-mL portions of water until the washings become neutral, and allow to stand. Shake the toluene extract with 3 g of anhydrous sodium sulfate, decant the toluene layer, distil the toluene under reduced pressure, and obtain a light-yellow, viscous liquid. When preserved at room temperature for a long time, it becomes a pale yellowish solid.

Absorbance <2.24\(^{*}\) E\(_{1}^{1}\)\(_{1}\)\(_{0}\) (286 nm): 38.0 – 42.0 (10 mg, chloroform, 100 mL).

Tolbutamide C_{12}H_{18}N_{2}O_{5} S [Same as the namesake monograph]

Toluene C_{6}H_{12}CH_{3} [K 8680, Special class]

\(\alpha\)-Toluene sulfonamide C_{6}H_{12}NO_{3}S Colorless crystals or white crystalline powder. Soluble in ethanol (95), and sparingly soluble in water.

Melting point <2.60\(^{*}\): 157 – 160°C
Purity p-Toluene sulfonamide—Use a solution of o-toluene sulfonamide in ethyl acetate (1 in 5000) as the sample solution. Perform the test with 10 μL of the sample solution as directed under Gas Chromatography <2.02> according to the operating conditions in the Purity (5) under Saccharin Sodium Hydrate: any peak other than the peak of o-toluene sulfonamide does not appear. Adjust the flow rate so that the retention time of o-toluene sulfonamide is about 10 minutes, and adjust the detection sensitivity so that the peak height of o-toluene sulfonamide obtained from 10 μL of the sample solution is about 50% of the full scale. Time span of measurement is about twice as long as the retention time of o-toluene sulfonamide beginning after the solvent peak.

Water <2.48>: not more than 0.5% (4 g, use 25 mL of methanol for Karl Fischer method and 5 mL of pyridine for Karl Fischer method).

Content: not less than 98.5%, calculated on the anhydrous basis. Assay—Weigh accurately about 0.025 g of o-toluene sulfonamide, and perform the test as directed under Nitrogen Determination <1.08>.

Each mL of 0.005 mol/L sulfuric acid VS = 1.712 mg of C6H5NO2S

O-Toluene sulfonamide CH3C6H4SO2NH2 White, crystals or crystalline powder. Melting point: about 137°C.

Purity Related substances—Dissolve 30 mg of p-toluene sulfonamide in acetone to make exactly 200 mL. Proceed with 10 μL of this solution as directed in the Purity (3) under Tolazamide: any peak other than the principal peak at the RI value of about 0.6 does not appear.

p-Toluene sulfonic acid See p-toluenesulfonic acid monohydrate.

p-Toluenesulfonic acid monohydrate CH3C6H4SO2H·H2O [K 8681, Special class]

O-Toluic acid C6H5CO2 White, crystals or crystalline powder.

Melting point <2.60>: 102 – 105°C

Content: not less than 98.0%.

Toluidine blue See toluidine blue O

Toluidine blue O C15H10ClN6S Dark green powder, soluble in water, and slightly soluble in ethanol (95).

Identification—

(1) A solution (1 in 100) shows a blue to purple color.

(2) A solution in ethanol (95) (1 in 200) shows a blue color.

(3) A solution shows a maximum absorption at around 630 nm.

Triamcinolone acetonide C24H31FO6 Same as the namesake monograph

Trichloroacetic acid CCl3COOH [K 8667, Special class]

Trichloroacetic acid-gelatin-tris buffer solution To 1 volume of a solution of trichloroacetic acid (1 in 5) add 6 volume of gelatin-tris buffer solution, pH 8.0 and 5 volume of water.

Trichloroacetic acid TS Dissolve 1.80 g of trichloroacetic acid, 2.99 g of sodium acetate trihydrate and 1.98 g of acetic acid (31) in water to make 100 mL.

Trichloroacetic acid TS for serrapeptase Dissolve 1.80 g of trichloroacetic acid and 1.80 g of anhydrous sodium acetate in 5.5 mL of 6 mol/L acetic acid TS and water to make 100 mL.

Trichlorofluoromethane CCl3F A colorless liquid or gas.

Specific gravity <2.50> d17.5: 1.494

Boiling point <2.57>: 23.7°C

1,1,2-Trichloro-1,2,2-trifluoroethane CFC12 CF2Cl Colorless volatile liquid. Miscible with acetone and with diethyl ether, and not with water.

Purity Related substances—Perform the test with 0.1 μL of 1,1,2-trichloro-1,2,2-trifluoroethane as directed under Gas Chromatography <2.02> according to the operating conditions in the Purity (5) under Halothane: any peak other than the peak of 1,1,2-trichloro-1,2,2-trifluoroethane does not appear.

Tricine C6H12NO3 White crystalline powder. Melting point: 182 to 184°C (with decomposition).

Triethanolamine See 2,2,2’-nitrilotriethanol.

Triethylamine C2H5N Clear colorless liquid, having a pungent odor. Miscible with methanol, with ethanol (95) and with diethyl ether.

Specific gravity <2.60> d20: 0.722 – 0.730

Boiling point <2.57>: 89 – 90°C

Triethylamine buffer solution, pH 3.2 To 4 mL of triethylamine add 2000 mL of water, and adjust the pH to 3.2 with phosphoric acid.

Triethylamine-phosphate buffer solution, pH 5.0 To 1.0 mL of triethylamine add 900 mL of water, adjust the pH to 5.0 with diluted phosphoric acid (1 in 10), and add water to make 1000 mL.

1% Triethylamine-phosphate buffer solution, pH 3.0 Dissolve 10 g of triethylamine in 950 mL of water, adjust the pH to 3.0 with phosphoric acid, and make exactly 1000 mL.

Trifluoroacetic acid CF3COOH Colorless, clear liquid, having a pungent odor. Miscible well with water.

Specific gravity <2.50> d20: 1.535

Boiling point <2.57>: 72 – 73°C

Trifluoroacetic acid for nuclear magnetic resonance spectroscopy CF3COOH Prepared for nuclear magnetic resonance spectroscopy.

Trifluoroacetic acid TS To 1 mL of trifluoroacetic acid add water to make 1000 mL.

Trifluoroacetic anhydride for gas chromatography (CF3CO)2O Colorless, clear liquid, having a pungent odor. Boiling point <2.57>: 40 – 45°C

Trimetazidine hydrochloride for assay C14H22N2O3·2HCl [Same as the monograph Trimetazidine Hydrochloride. It contains not less than 99.0% of trimetazidine hydrochloride (C14H22N2O3·2HCl), calculated on the anhydrous basis.]

Trimethylsilyl imidazole C6H12N3Si Clear, colorless to pale yellow liquid.

Refractive index <2.45> nD: 1.4744 – 1.4764

2,4,6-trinitrobenzenesulfonic acid See 2,4,6-trinitroben-
2.4,6-Trinitrobenzenesulfonic acid dihydrate
\(\text{C}_6\text{H}_5\text{K}_3\text{O}_7\cdot\text{H}_2\text{O}\) Pale yellow to light yellow powder.

Water \(\leq 2.4\%\): 11–15% (0.1 g, volumetric titration, direct titration).

**Content:** not less than 98%, calculated on the anhydrous basis. Assay—Weigh accurately about 0.3 g of 2,4,6-trinitrobenzenesulfonic acid, dissolve in 50 mL of a mixture of water and ethanol (99.5) (1:1), and titrate \(\leq 2.5\%\) with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 29.32 mg of \(\text{C}_6\text{H}_5\text{K}_3\text{O}_7\cdot\text{H}_2\text{O}\)

2,4,6-Trinitrophenol \(\text{HOC}_6\text{H}_2(\text{NO}_2)_3\) Light yellow to yellow, moist crystals. It is added 15 to 25% of water for the sake of safety, because it might explode by heating, mechanical shocking and friction when it is dried.

**Identification:**—To 0.1 g add 10 mL of water, dissolve by warming, and add 12 mL of a mixture of 1% copper (II) sulfate solution and ammonia TS (5:1): green precipitates appear.

**Content:** not less than 99.5%. Assay—Weigh accurately about 0.25 g, previously dried in a desiccator (silica gel) for warming, and add 12 mL of a mixture of 1% copper (II) sulfate solution and ammonia TS (5:1): green precipitates appear.

Each mL of 0.1 mol/L sodium hydroxide VS = 22.91 mg of \(\text{HOC}_6\text{H}_2(\text{NO}_2)_3\)

**Identification:**—To 0.1 g of triphenylmethanol for thin-layer chromatography in 100 mL of methanol and perform the chromatography in 100 mL for the sake of safety, because it might explode by heating, mechanical shocking and friction when it is dried.

**Identification:**—To 0.1 g add 10 mL of water, dissolve by warming, and add 12 mL of a mixture of 1% copper (II) sulfate solution and ammonia TS (5:1): green precipitates appear.

**Content:** not less than 99.5%. Assay—Weigh accurately about 0.25 g, previously dried in a desiccator (silica gel) for warming, and add 12 mL of a mixture of 1% copper (II) sulfate solution and ammonia TS (5:1): green precipitates appear.

Each mL of 0.1 mol/L sodium hydroxide VS = 22.91 mg of \(\text{HOC}_6\text{H}_2(\text{NO}_2)_3\)

2,4,6-Trinitrophenol-ethanol TS Dissolve 1 g of 2,4,6-trinitrophenol in 50 mL of diluted ethanol (99.5) (9 in 10) and adjust the pH to 7.0 with 0.1 mol/L hydrochloric acid TS. Use within 2 days.

2,4,6-Trinitrophenol TS, alkaline Mix 20 mL of 2,4,6-trinitrophenol TS with 10 mL of a solution of sodium hydroxide (1 in 20), and add water to make 100 mL. Use within 2 days.

Triphenylmethanol for thin-layer chromatography
\(\text{C}_9\text{H}_8\text{O}_2\) Occurs as a white powder.

**Purity:** Dissolve 0.1 g of triphenylmethanol for thin-layer chromatography in 100 mL of methanol and perform the test as directed in the Purity (2) under Zidovudine: spots other than the principal spot with an Rf value of about 0.73 are not observed.

Triphenyltetrazolium chloride See 2,3,5-triphenyl-2H-tetrazolium chloride.

2,3,5-Triphenyl-2H-tetrazolium chloride TS See 2,3,5-triphenyl-2H-tetrazolium chloride TS.

2,3,5-Triphenyl-2H-tetrazolium chloride \(\text{C}_{19}\text{H}_{15}\text{ClN}_4\) [K 8214, Special class]
0.05 mol/L Tris buffer solution, pH 7.0  Dissolve 6.06 g of 2-amino-2-hydroxymethyl-1,3-propanediol in about 750 mL of water, adjust to pH 7.0 with 1 mol/L hydrochloric acid TS, and add water to make 1000 mL.

0.05 mol/L Tris buffer solution, pH 8.6  Dissolve 6.1 g of 2-amino-2-hydroxymethyl-1,3-propanediol in 950 mL of water, add 2 mol/L hydrochloric acid TS to adjust the pH to 8.6, and then add water to make 1000 mL.

Tris(4-butyphenyl)phosphate $[(CH_3)_3C_6H_4O]_3PO$ White crystals or crystalline powder. Melting point $<2.60^\circ$: 100 – 104°C

0.2 mol/L Tris-hydrochloride buffer solution, pH 7.4  Dissolve 6.61 g of 2-amino-2-hydroxymethyl-1,3-propanediol hydrochloride and 0.97 g of 2-amino-2-hydroxymethyl-1,3-propanediol in water to make 250 mL.

0.05 mol/L Tris-hydrochloride buffer solution, pH 7.5  Dissolve 6.35 g of 2-amino-2-hydroxymethyl-1,3-propanediol hydrochloride and 1.18 g of 2-amino-2-hydroxymethyl-1,3-propanediol in water to make 1000 mL.

Tris(hydroxymethyl)aminomethane  See 2-amino-2-hydroxymethyl-1,3-propanediol.

Trisodium citrate dihydrate  See sodium citrate dihydrate.

0.1 mol/L Trisodium citrate TS  Dissolve 29.4 g of trisodium citrate dihydrate in water to make 1000 mL.

Trisodium ferrous pentacyanoamine TS  See iron (II) trisodium pentacyanoamine TS.

Trisodium phosphate dodecahydrate

Trypsin for liquid chromatography  An enzyme obtained from the bovine pancreas. This one part digests 250 parts of casein in the following reaction system.

Casein solution—To 0.1 g of milk casein add 30 mL of water, disperse the casein well, add 1.0 mL of diluted sodium hydroxide TS (1 in 10) to dissolve, and add water to make 50 mL. Prepare before use.

Sample solution—Dissolve 0.01 g of trypsin for liquid chromatography in 500 mL of water.

Procedure—To 5 mL of the casein solution add 2 mL of the sample solution and 3 mL of water, mix, then allow to stand at 40°C for 1 hour, and add 3 drops of a mixture of 95% water, and slightly soluble in cold water. Prepare before use.

Procedure—To 5 mL of the casein solution add 2 mL of the sample solution and 3 mL of water, mix, then allow to stand at 40°C for 1 hour, and add 3 drops of a mixture of 95% water, and slightly soluble in cold water. Prepare before use.

Trypsin for liquid chromatography  An enzyme obtained from the bovine pancreas. This one part digests 250 parts of casein in the following reaction system.

Casein solution—To 0.1 g of milk casein add 30 mL of water, disperse the casein well, add 1.0 mL of diluted sodium hydroxide TS (1 in 10) to dissolve, and add water to make 50 mL. Prepare before use.

Sample solution—Dissolve 0.01 g of trypsin for liquid chromatography in 500 mL of water.

Procedure—To 5 mL of the casein solution add 2 mL of the sample solution and 3 mL of water, mix, then allow to stand at 40°C for 1 hour, and add 3 drops of a mixture of 95% water, and slightly soluble in cold water. Prepare before use.

Trypsin for test of elcatonin  Dissolve 5 mg of trypsin for liquid chromatography in 20 mL of solution of ammonium hydrogen carbonate (1 in 100). Prepare before use.

Trypsin for test of ulinastatin  Dissolve crystalline trypsin for ulinastatin assay in ice-cooled 1 mmol/L hydrochloric acid TS containing 1 mmol/L calcium chloride dihydrate so that each mL of the solution contains 180 μg of trypsin. Prepare before use, and preserve in an ice-cooled water bath.

L-Tryptophan  C$_6$H$_5$N$_2$O$_2$ [Same as the namesake monograph]

Ubenimex for assay  C$_8$H$_8$N$_4$O$_4$ [Same as the monograph Ubenimex. When dried, it contains not less than 99.9% of ubenimex (C$_8$H$_8$N$_4$O$_4$)].

Ubiquinone-9  Yellow to orange, crystalline powder. Odorless and tasteless. Freely soluble in formic acid, very slightly soluble in water, and practically insoluble in ethanol (95) and in diethyl ether. It dissolves in dilute hydrochloric acid and in dilute nitric acid.

Optical rotation $<2.49 > [\alpha]_D^2$: $-10.5$ to $-12.5^\circ$ (after drying, 2.5 g, 1 mol/L hydrochloric acid TS, 50 mL, 100 mm).

Loss on drying $<2.47 >$: not more than 0.30% (1 g, 105°C, 3 hours).

Content: not less than 99.0%. Assay—Weigh accurately about 0.3 g of L-tyrosine, previously dried, dissolve in 6 mL of formic acid, add 50 mL of acetic acid (100), and titrate $<2.50$ with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 18.12 mg of C$_6$H$_5$N$_2$O$_2$

Ubenimex for assay  C$_8$H$_8$N$_4$O$_4$ [Same as the monograph Ubenimex. When dried, it contains not less than 99.9% of ubenimex (C$_8$H$_8$N$_4$O$_4$)].

Urea  H$_2$NCONH$_2$ [K 8731, Special class]

Urethane  See ethyl carbamate.

Ursodeoxycholic acid  C$_24$H$_40$O$_4$ [Same as the namesake monograph]

Ursodeoxycholic acid for assay  C$_24$H$_40$O$_4$ [Same as the namesake monograph. However, when dried, it contains not less than 99.0% of ursodeoxycholic acid (C$_24$H$_40$O$_4$) meeting the following additional specifications.]

Purity  Related substances—Dissolve 0.15 g of ursodeoxycholic acid for assay in 5 mL of methanol for liquid chromatography, and use this solution as the sample solution. Pipet 0.2 mL of this solution and add methanol for liquid chromatography to make exactly 50 mL. Pipet 2.5 mL of this solution, add methanol for liquid chromatography to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 0.5 mL each of the sample solution and standard solution as directed under Liquid Chromatography $<2.01 >$ according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the area of the peak, having the relative retention time of about 2.5 with respect to ursodeoxycholic acid, obtained from the sample solution is not larger...
than the peak area of ursodeoxycholic acid from the standard solution, and the area of the peak, having the relative retention time of about 3.5, obtained from the sample solution is not larger than 1/5 times the peak area of ursodeoxycholic acid from the standard solution. Furthermore, the total area of the peaks other than the peak of ursodeoxycholic acid and other than the peaks mentioned above is not larger than 1/5 times the peak area of ursodeoxycholic acid from the standard solution.

Operating conditions
Detector: An ultraviolet absorption photometer (wavelength: 210 nm).
Column: A stainless steel column 3 mm in inside diameter and 7.5 cm in length, packed with octylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Mobile phase: A mixture of methanol for liquid chromatography, diluted phosphoric acid (1 in 1000) and acetonitrile for liquid chromatography (96:69:35).
Flow rate: Adjust the flow rate so that the retention time of ursodeoxycholic acid is about 2.3 minutes.
Time span of measurement: About 7 times as long as the retention time of ursodeoxycholic acid.
System suitability
Test for required detectability: Pipet 2 mL of the standard solution, and add methanol for liquid chromatography to make exactly 20 mL. Confirm that the peak area of ursodeoxycholic acid obtained from 5 μL of this solution is equivalent to 8 to 12% of that of ursodeoxycholic acid from 5 μL of the standard solution.
System performance: To 30 mg of chenodeoxycholic acid for thin-layer chromatography and 30 mg of lithocholic acid for thin-layer chromatography, add 1 mL of the sample solution, dissolve in methanol for liquid chromatography to make 50 mL. When the procedure is run with 5 μL of this solution under the above operating conditions, ursodeoxycholic acid, chenodeoxycholic acid, and lithocholic acid are eluted in this order with the resolution between these peaks being not less than 7, respectively.
System repeatability: When the test is repeated 6 times with 5 μL of the standard solution under the above conditions, the relative standard deviation of the peak area of ursodeoxycholic acid is not more than 2.0%.

\( n \)-Valerianic acid \( \text{CH}_3(\text{CH}_2)_3\text{COOH} \) Clear, colorless to pale yellow liquid, having a characteristic odor. Miscible with ethanol (95) and with diethyl ether, and soluble in water.

Specific gravity \(< 2.56\) \( d^2_{40} \): 0.936 – 0.942
Distilling range \(< 2.57\) : 186 – 188°C, not less than 98 vol%.

\( L \)-Valine \( \text{C}_5\text{H}_9\text{NO}_2 \) [Same as the namesake monograph]

\( L \)-Valine for assay \( \text{C}_5\text{H}_9\text{NO}_2 \) [Same as the monograph \( L \)-Valine. When dried, it contains not less than 99.0% of \( L \)-valine (\( \text{C}_5\text{H}_9\text{NO}_2 \)).]

\( \text{H}-\text{d}-\text{Valyl-t-Leucyl-\text{L}-arginine n-nitroanilide d} \) dihydrochloride \( \text{C}_9\text{H}_{14}\text{N}_4\text{O}_2\cdot2\text{HCl} \) White to pale yellow, powder or masses. Sparingly soluble in water.

Absorbance \(< 2.24\) \( E^\%_{1%\text{m}} \) (316 nm): 214 – 236 (0.01 g, water, 500 mL).

**Vanadium pentoxide** See vanadium (V) oxide.

**Vanadium pentoxide TS** See vanadium (V) oxide TS.

**Vanadium pentoxide, dilute** See vanadium (V) oxide TS, dilute.

**Vanadium (V) oxide** \( \text{V}_2\text{O}_5 \) Orangish yellow to yellow-brown powder.

Identification—Dissolve 0.3 g in 10 mL of ammonia TS and 15 mL of water. To 2 mL of this solution add 20 mL of water, mix, and add gently 1 mL of copper (II) sulfate TS: yellow precipitates appear.

**Vanadium (V) oxide TS** Add vanadium (V) oxide to phosphoric acid, saturate with vanadium (V) oxide by shaking vigorously for 2 hours, and filter through a glass filter.

**Vanadium (V) oxide TS, dilute** Dilute 10 mL of vanadium (V) oxide TS with water to make 100 mL. Prepare before use.

**Vanillin** \( \text{C}_6\text{H}_5\text{CHO(OCH}_3\text{)(OH)} \) A white to light yellow crystalline powder, having a characteristic odor.

Melting point \(< 2.60\) : 80.5 – 83.5°C.

Preserve in a light-resistant tight container.

**Vanillin-hydrochloric acid TS** Dissolve 5 mg of vanillin in 0.5 mL of ethanol (95), and to this solution add 0.5 mL of water and 3 mL of hydrochloric acid. Prepare before use.

**Vanillin-sulfuric acid-ethanol TS** Dissolve 3 g of vanillin in 30 mL of ethanol (95.9), and add 100 mL of sulfuric acid.

**Vanillin-sulfuric acid-ethanol TS for spraying** Dissolve 3 g of vanillin in 30 mL of ethanol (95.9), and add 100 mL of dilute sulfuric acid.

**Vanillin-sulfuric acid TS** Add cautiously 75 mL of sulfuric acid to 25 mL of ice-cold ethanol (95). After cooling, add 1 g of vanillin to dissolve. Prepare before use.

**Vasopressin** \( \text{C}_{46}\text{H}_{65}\text{N}_{15}\text{O}_{12}\text{S}_2 \) A white powder.

Constituent amino acids—Perform the test as directed in the Constituent amino acids under Oxytocin, and calculate the respective molar ratios with respect to glycine: 0.9 – 1.1 for aspartic acid, 0.9 – 1.1 for glutamic acid, 0.9 – 1.1 for proline, 0.8 – 1.1 for tyrosine, 0.9 – 1.1 for phenylalanine, 0.9 – 1.1 for arginine and 0.8 – 1.1 for cystine, and not more than 0.03 for other amino acids.

**Verapamil hydrochloride for assay** \( \text{C}_{36}\text{H}_{58}\text{N}_4\text{O}_9\text{HCl} \) [Same as the monograph Verapamil Hydrochloride. When dried, it contains not less than 99.0% of verapamil hydrochloride (\( \text{C}_{36}\text{H}_{58}\text{N}_4\text{O}_9\text{HCl} \)).]

**Vinblastine sulfate** \( \text{C}_{46}\text{H}_{56}\text{N}_4\text{O}_10\text{H}_2\text{SO}_4 \) [Same as the namesake monograph]

**Vincristine sulfate** \( \text{C}_{46}\text{H}_{58}\text{N}_4\text{O}_{10}\text{H}_2\text{SO}_4 \) [Same as the namesake monograph]

**Vinyl acetate** \( \text{C}_2\text{H}_4\text{O}_2 \) Clear, colorless liquid.

Specific gravity \(< 2.56\) \( d^2_{40} \): 0.932 – 0.942
Distilling range \(< 2.57\) : 80.5 – 83.5°C.

**Water** \( \leq 2.48\) : not more than 0.2%.

**Vinyl chloride** \( \text{C}_2\text{H}_3\text{Cl} \) Colorless gas.

Boiling point \(< 2.57\) : –14°C
Melting point \(< 2.60\) : –160°C
2-Vinylpyridine C₇H₇N A clear, colorless or dark brown liquid.

Refractive index <2.45> nD²⁰: 1.546 – 1.552

Specific gravity <2.56> d₄³: 0.975 – 0.982

1-Vinyl-2-pyrrolidone C₅H₈NO Clear liquid.

Purity—Perform the test with 0.5 μL of 1-vinyl-2-pyrrolidone as directed under Gas Chromatography <2.02> according to the following conditions. Determine each peak area of the solutions by the automatic integration method, and calculate the amount of 1-vinyl-2-pyrrolidone by the area percentage method: it is not less than 99.0%.

Operating conditions
Detector: A hydrogen flame-ionization detector.
Column: A hollow, capillary glass column about 0.53 mm in inside diameter and about 30 m in length, having an about 1.0-μm layer of polyethylene glycol 20 M for gas chromatography on the inner side.

Column temperature: Maintain the temperature at 80°C for 1 minute, then raise at the rate of 10°C per minute to 190°C, and hold constant to the temperature for 20 minutes.

Temperature of sample vaporization chamber: A constant temperature of about 190°C.
Carrier gas: Helium.
Flow rate: Adjust the flow rate so that the retention time of 1-vinyl-2-pyrrolidone is about 15 minutes.
Detection sensitivity: Adjust the detection sensitivity so that the peak height of 1-vinyl-2-pyrrolidone from 0.5 μL of 1-vinyl-2-pyrrolidone is about 70% of the full scale.

Time span of measurement: About twice as long as the retention time of 1-vinyl-2-pyrrolidone beginning after the solvent peak.

Water <2.48>—Take 50 mL of methanol for Karl Fischer method and 10 mL of butyrolactone in a dry titration flask, and titrate with Karl Fischer TS until end point. Weigh accurately about 2.5 g of 1-vinyl-2-pyrrolidone, transfer immediately to a titration flask, and perform the test: water is not more than 0.1%.

V₈ protease A protease obtained from Staphylococcus aureus strain. When an amount of the enzyme hydrolyzes 1 mg/mL. Keep at a cold place and use within 6 days after preparation.

Voglibose for assay C₁₀H₁₂NO₇ [Same as the monograph Voglibose]

Warfarin potassium for assay [Same as the monograph Warfarin Potassium. When dried, it contains not less than 99.0% of warfarin potassium (C₁₉H₁₅KO₄).]

25% Water containing benzoil peroxide See Benzoil peroxide, 25% water containing.

Water for ammonium limit test To 1500 mL of water add cautiously 4.5 mL of sulfuric acid, distil using a hard glass distiller, discard the sufficient volume of first distillate, and use the remaining distillate (ammonium-free water) as the water for ammonium limit test.

Purity—Mix 40 mL of water for ammonium limit test with 6.0 mL of phenol-sodium pentacyanonitrosylferrate (III) TS. Add 4.0 mL of sodium hypochlorite-sodium hydroxide TS, mix, and allow to stand for 60 minutes. Perform the test with this solution as directed under Ultraviolet-visible Spectrophotometry <2.24>, using water as the blank: the absorbance at 640 nm is not more than 0.010.

Water for bacterial endotoxins test [Use the water described under the monographs of Water for Injection or Sterile Water for Injection in Containers, or the water produced by other procedures that shows no reaction with the lysate reagent employed, at the detection limit of the reagent, and is suitable for bacterial endotoxins test.]

Water for injection [Use the water described under the monographs of Water for Injection or Sterile Water for Injection in Containers. It is not necessary to check the conformity to all the specification items of the monograph, if it is confirmed that the water to be used is suitable for the purpose of relevant test.]

Water, sterile purified [Use the water described by the monograph of Sterile Purified Water in Containers. It is not necessary to check the conformity to all the specification items of the monograph, if it is confirmed that the water to be used is suitable for the purpose of relevant test.]

Wijs’ TS Transfer 7.9 g of iodine trichloride and 8.9 g of iodine to separate flasks, dissolve each with acetic acid (100), mix both solutions, and add acetic acid (100) to make 1000 mL. Preserve in light-resistant, glass containers.

Wogonin for thin-layer chromatography C₂₀H₂₀O₆ Yellow crystals or crystalline powder. Slightly soluble in methanol and in ethanol (99.5), and practically insoluble in water. Melting point: 204 – 208°C

Identification—Determine the absorption spectrum of a solution in methanol (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry <2.24> it exhibits maxima between 207 nm and 211 nm, and between 273 nm and 277 nm.

Purity Related substances—Dissolve 1 mg in 1 mL of methanol, and perform the test with 10 μL of this solution as directed in the Identification (3) under Saireito Extract: no spot other than the principal spot (Rf value is about 0.4) appears.

Xanthene C₁₃H₁₀O White to light yellow crystals or crystalline powder, having a slight, characteristic odor.

Melting point <2.48>: 98 – 102°C

Water <2.48>: not more than 0.5% (0.15 g).

Xanthene-9-carboxylic acid C₁₅H₁₂O₃ Dissolve 0.25 g of propantheline bromide in 5 mL of water and 10 mL of sodium hydroxide TS, heat the mixture to boiling, then continue to heat for 2 minutes. Cool to 60°C, add 5 mL of dilute sulfuric acid, cool, filter the precipitate, and wash thoroughly with water. Recrystallize the residue from dilute ethanol, and dry for 3 hours in a desiccator (in vacuum, silica gel).

Melting point <2.60>: 217 – 222°C

Xanthone C₁₃H₁₆O₂ Light yellow powder. Freely soluble in chloroform, and slightly soluble in hot water and in diethyl ether.

Melting point <2.60>: 174 – 176°C

Purity Related substances—Dissolve 0.050 g of xanthone in chloroform to make exactly 10 mL. Perform the test with 5 μL of this solution as directed in the Purity under Propan-
Xanthodyl \( \text{C}_9\text{H}_2\text{O}_2 \) White to pale yellow powder. Dissolves in ethanol (95%), in diethyl ether, in chloroform, and in acetic acid (100), and is practically insoluble in water.

Melting point 〈2.60〉: 121 - 124°C
Residue on ignition 〈2.44〉: not more than 2.0% (0.5 g).

Xylene \( \text{C}_6\text{H}_4(\text{CH}_3)_2 \) 〈K 8271, First class〉

\( \alpha \)-Xylene \( \text{C}_6\text{H}_4(\text{CH}_3)_2 \) Colorless, clear liquid.
Refractive index 〈2.45〉: \( n_\rho^2 \): 1.501 - 1.506
Specific gravity 〈2.56〉: \( d_\rho^2 \): 0.875 - 0.885
Distilling range 〈2.57〉: 143 - 146°C, not less than 95 vol%.

Xylene cyanol FF \( \text{C}_3\text{H}_2\text{N}_2\text{Na}_2\text{O}_8\text{Zn}.4\text{H}_2\text{O} \) White powder. The pH of a solution of 0.01 mol/L bismuth nitrate VS until the color of the solution changes from yellow to red (indicator: 2 drops of xylenol orange TS).

\( \alpha \)-Xylene \( \text{C}_6\text{H}_4(\text{CH}_3)_2 \) Colorless, clear liquid.
Refractive index 〈2.45〉: \( n_\rho^2 \): 1.501 - 1.506
Specific gravity 〈2.56〉: \( d_\rho^2 \): 0.875 - 0.885
Distilling range 〈2.57〉: 143 - 146°C, not less than 95 vol%.

Xylene cyanol FF

Zinc acetate dihydrate \( \text{Zn(CH}_3\text{COO})_2.2\text{H}_2\text{O} \) 〈K 8356, Special class〉

Zinc, arsenic-free See zinc for arsenic analysis.

Zinc chloride \( \text{ZnCl}_2 \) 〈K 8111, Special class〉

Zinc chloride TS Dissolve 10 g of zinc chloride and 10 g of potassium hydrogen phthalate in 900 mL of water, adjust the pH to 4.0 with sodium hydroxide TS, and add water to make 1000 mL.

0.04 mol/L Zinc chloride TS Dissolve 5.452 g of zinc chloride in water to make 1000 mL.

Zinc diethylidithiocarbamate See Test Methods for Plastic Containers 〈7.02〉.

Zinc dibutylidithiocarbamate See Test Methods for Plastic Containers 〈7.02〉.

Zinc disodium ethylenediamine tetraacetate See zinc disodium ethylenediamine tetraacetate tetrahydrate.

Zinc disodium ethylenediamine tetraacetate tetrahydrate \( \text{C}_9\text{H}_2\text{N}_2\text{Na}_2\text{O}_4\text{Zn}.4\text{H}_2\text{O} \) White powder. The pH of a solution of zinc disodium ethylenediamine tetraacetate (1 in 100) is between 6.0 and 9.0.

Purity Clarity and color of solution—Dissolve 0.1 g of zinc disodium ethylenediamine tetraacetate tetrahydrate in 10 mL of freshly boiled and cooled water: the solution is clear and colorless.

Content: not less than 98.0%. Assay—Dissolve about 0.5 g of zinc disodium ethylenediamine tetraacetate tetrahydrate, accurately weighed, in water to make exactly 100 mL. Pipet 10 mL of this solution, adjust the pH to about 2 with 80 mL of water and dilute nitric acid, and titrate 〈2.50〉 with 0.01 mol/L bismuth nitrate VS until the color of the solution changes from yellow to red (indicator: 2 drops of xylene orange TS).

Each mL of 0.01 mol/L bismuth nitrate VS = 4.716 mg of \( \text{C}_9\text{H}_2\text{N}_2\text{Na}_2\text{O}_4\text{Zn}.4\text{H}_2\text{O} \).

Zinc dust See zinc powder.

Zinc for arsenic analysis \( \text{Zn} \) 〈K 8012〉 Use granules of about 800 \( \mu \)m.

Zinc iodide-starch TS To 100 mL of boiling water add a solution of 0.75 g of potassium iodide in 5 mL of water, a solution of 2 g of zinc chloride in 10 mL of water and a smooth suspension of 5 g of starch in 30 mL of water, with stirring. Continue to boil for 2 minutes, then cool.

Sensitivity—Dip a glass rod into a mixture of 1 mL of 0.1 mol/L sodium nitrite VS, 500 mL of water and 10 mL of hydrochloric acid, and touch on zinc iodide-starch paste TS: an apparently blue color appears.

Storage—Preserve in tightly stoppered bottles, in a cold place.

Zincon \( \text{C}_{20}\text{H}_{15}\text{N}_2\text{Na}_2\text{O}_4 \) A dark red to purple powder.

Identification—Determine the infrared absorption spectrum of zincon, previously dried at 105°C for 4 hours, as directed in the potassium bromide disk method as directed under Infrared Spectrophotometry 〈2.25〉: it exhibits absorption at the wave numbers of about 1604 cm\(^{-1}\), 1494 cm\(^{-1}\), 1294 cm\(^{-1}\), 1194 cm\(^{-1}\), 1110 cm\(^{-1}\), 1046 cm\(^{-1}\) and 764 cm\(^{-1}\).
Preserve in a light-resistant tight container.

**Zinc**

**Zinc sulfate** See zinc sulfate heptahydrate.

**Zinc sulfate for volumetric analysis** See zinc sulfate heptahydrate.

**Zinc sulfate heptahydrate** ZnSO$_4$·7H$_2$O [K 8953, Special class]

**Zinc sulfate TS** Dissolve 10 g of zinc sulfate heptahydrate in water to make 100 mL.

**Zirconyl-alizarin red S TS** Dissolve 0.2 g of zirconyl nitrate in 5 mL of dilute hydrochloric acid, add 10 mL of alizarin red S TS, and then add water to make 30 mL.

**Zirconyl-alizarin S TS** See zirconyl-alizarin red S TS.

**Zirconyl nitrate** See zirconyl nitrate dihydrate.

**Zirconyl nitrate dihydrate** ZrO(NO$_3$)$_2$·2H$_2$O A white crystalline powder. Freely soluble in water.

*Identification*—(1) To 5 mL of a solution (1 in 20) add 5 mL of sodium hydroxide TS: a white, milky precipitate is formed.

(2) To 10 mL of a solution (1 in 20) add 10 mL of sulfuric acid, cool, and superimpose 2 mL of iron (II) sulfate TS: a brown ring is produced at the zone of contact.

**Zolpidem tartrate for assay** (C$_{19}$H$_{21}$N$_3$O)$_2$·C$_4$H$_6$O$_6$ [Same as the monograph Zolpidem Tartrate. It contains not less than 99.5% of zolpidem tartrate [(C$_{19}$H$_{21}$N$_3$O)$_2$·C$_4$H$_6$O$_6$], calculated on the anhydrous basis.]

### 9.42 Solid Supports/Column Packings for Chromatography

**Aminopropylsilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**Carbamoyl group bound silica gel for liquid chromatography** Prepared for liquid chromatography.

**Cellulose for thin-layer chromatography** Use a high-grade cellulose prepared for thin-layer chromatography.

**Cellulose with fluorescent indicator for thin-layer chromatography** Use cellulose for thin-layer chromatography containing a suitable fluorescent substance.

**Cyanopropylsilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**DEAE-cross-linking dextran anion exchanger (Cl type), slightly alkaline** Slightly alkaline anion exchanger prepared by introducing diethylaminoethyl group into cross-linking dextran of gel filtration carrier.

**Diethylaminoethyl cellulose for column chromatography** Prepared for column chromatography.

**Diethylaminomethyl group bound to synthetic polymer for liquid chromatography** Produced by binding diethylaminomethyl group to a hydrophilic synthetic polymer, for liquid chromatography. Exchange volume is about 0.1 mg equivalents/cm$^3$.

**Dimethylaminopropylsilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**Dimethyilsilanized silica gel with fluorescent indicator for thin-layer chromatography** Dimethyilsilanized silica gel for thin-layer chromatography to which a fluorescent indicator is added.

**Diol silica gel for liquid chromatography** Prepared for liquid chromatography.

**Divinylbenzene-methacrylate co-polymer for liquid chromatography** Prepared for liquid chromatography.

**Divinylbenzene-N-vinyl pyrrolidone copolymer for column chromatography** Prepared for column chromatography.

**Fluorosilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**Gel-type strong acid cation-exchange resin for liquid chromatography (degree of cross-linkage: 8%)** Prepared for liquid chromatography.

**Gel type strong acid ion-exchange resin for liquid chromatography (degree of cross-linkage: 6%)** Prepared for liquid chromatography.

**Glycol etherifized silica gel for liquid chromatography** Glycol group is bound to silica gel for liquid chromatography.

**Graphite carbon for gas chromatography** Prepared for gas chromatography.

**Hexasilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**Hydrophilic silica gel for liquid chromatography** Diolized porous silica gel prepared for liquid chromatography (5-10 μm in particle diameter).

**Hydroxypropylsilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**Neutral alumina for chromatography** Prepared for chromatography (75 – 180 μm in particle diameter).

**Neutral alumina for column chromatography** Prepared for column chromatography.

**Octadecylsilanized polyvinyl alcohol gel polymer for liquid chromatography** Prepared for liquid chromatography.

**Octadecylsilanized silica gel for liquid chromatography** Prepared for liquid chromatography.

**Octadecylsilanized silica gel for thin-layer chromatography** Octadecylsilanized silica gel prepared for thin-layer chromatography.

**Octadecylsilanized silica gel with fluorescent indicator for thin-layer chromatography** Octadecylsilanized silica gel for thin-layer chromatography containing fluorescent indicator.
Octadecylsilanized silicone polymer coated silica gel for liquid chromatography Prepared for liquid chromatography.

Octylsilanized silica gel for liquid chromatography Prepared for liquid chromatography.

Pentaethylenehexamminated polyvinyl alcohol polymer bead for liquid chromatography Prepared for liquid chromatography.

Phenyalted silica gel for liquid chromatography Prepared for liquid chromatography.

Phenylisilanized silica gel for liquid chromatography Prepared for liquid chromatography.

Polyamide for column chromatography Prepared for column chromatography.

Polyamide for thin-layer chromatography Prepared for thin-layer chromatography.

Polyamide with fluorescent indicator for thin-layer chromatography Add a fluorescent indicator to polyamide for thin-layer chromatography.

Porous acrylonitrile-divinylbenzene copolymer for gas chromatography (pore diameter: 0.06 – 0.08 \(\mu m\), 100 – 200 \(m^2/g\)) A porous acrylonitrile-divinylbenzene copolymer prepared for gas chromatography. The average pore diameter is 0.075 \(\mu m\), and surface area is 500 to 600 \(m^2/g\).

Porous ethyl vinybenzene-divinylbenzene copolymer for gas chromatography Prepared for gas chromatography.

A porous ethylvinylbenzene-divinylbenzene copolymer for gas chromatography (average pore diameter: 0.0075 \(\mu m\), 500 – 600 \(m^2/g\)) A porous ethylvinylbenzene-divinylbenzene copolymer prepared for gas chromatography. The average pore diameter is 0.0075 \(\mu m\), and surface area is 500 to 600 \(m^2/g\).

Porous polymer beads for gas chromatography Prepared for gas chromatography.

Porous silica gel for liquid chromatography A porous silica gel prepared for liquid chromatography.

Porous styrene-divinylbenzene copolymer for gas chromatography (average pore diameter: 0.0085 \(\mu m\), 300 – 400 \(m^2/g\)) A porous styrene-divinylbenzene copolymer prepared for gas chromatography. The average pore diameter is 0.0085 \(\mu m\), and surface area is 300 to 400 \(m^2/g\).

Porous styrene-divinylbenzene copolymer for liquid chromatography A porous styrene-divinylbenzene copolymer prepared for liquid chromatography.

Quaternary alkylaminated styrene-divinylbenzene copolymer for liquid chromatography Prepared for liquid chromatography.

Silica gel for gas chromatography A silica gel prepared for gas chromatography.

Silica gel for liquid chromatography A silica gel prepared for liquid chromatography.

Silica gel for liquid chromatography with attached carbamoyl groups Prepared for liquid chromatography.

Silica gel for thin-layer chromatography A silica gel prepared for thin-layer chromatography.

Silica gel for thin-layer chromatography (particle size 5 – 7 \(\mu m\), with fluorescent indication) Prepared for high-performance thin-layer chromatography.

Silica gel with complex fluorescent indicator for thin-layer chromatography A silica gel for thin-layer chromatography containing suitable complex fluorescent indicators.

Silica gel with fluorescent indicator for thin-layer chromatography A silica gel for thin-layer chromatography containing a suitable fluorescent indicator.

Siliceous earth for chromatography A siliceous earth prepared for chromatography.

Siliceous earth for gas chromatography A siliceous earth prepared for gas chromatography.

Slightly acidic ion-exchange silica gel for liquid chromatography Prepared for liquid chromatography.

Strongly acidic ion-exchange resin for column chromatography Prepared for column chromatography.

Strongly acidic ion-exchange resin for liquid chromatography Prepared for liquid chromatography.

Strongly acidic ion-exchange silica gel for liquid chromatography Prepared for liquid chromatography.

Strongly basic ion-exchange resin for column chromatography Prepared for column chromatography.

Styrene-divinylbenzene copolymer for liquid chromatography Prepared for liquid chromatography.

Sulfonamide group bound to hexadecylsilanized silica gel for liquid chromatography Prepared for column chromatography.

Synthetic magnesium silicate for column chromatography Prepared for column chromatography (150 – 250 \(\mu m\) in particle diameter).

Teflon for gas chromatography See Tetrafluoroethylene polymer for gas chromatography.

Terephthalic acid for gas chromatography \(C_8H_6(COOH)_2\) Prepared for gas chromatography.

Tetrafluoroethylene polymer for gas chromatography Prepared for gas chromatography.

Trimethylsilanized silica gel for liquid chromatography Prepared for liquid chromatography.

Weakly acidic CM-bridged cellulose cation exchanger (H type) Weakly acidic cation exchanger, intensified by crosslinking porous spherical cellulose, into which carboxymethyl groups have been introduced.

Weakly acidic ion exchange resin for liquid chromatography Prepared for liquid chromatography.

Weakly acidic ion exchange silica gel for liquid chromatography Prepared for liquid chromatography.

Zeolite for gas chromatography (0.5 nm in pore diameter) Zeolite prepared for gas chromatography.
9.43 Filter Papers, Filters for filtration, Test Papers, Crucibles, etc.

Filter paper  [R 3801, Filter paper (for chemical analysis), Filter paper for qualitative analysis]
No.1: For bulky gelatinous precipitate
No.2: For moderate-sized precipitate
No.3: For fine precipitate
No.4: Hardened filter paper for fine precipitate

Filter paper for quantitative analysis  [R 3801, Filter paper (for chemical analysis), Filter paper for quantitative analysis]
No. 5A: For bulky gelatinous precipitate
No. 5B: For moderate-sized precipitate
No. 5C: For fine precipitate
No. 6: Thin filter paper for fine precipitate

Porcelain crucible  [R 1301, Porcelain crucible for chemical analysis]

Sintered glass filter  [R 3503, Glass appliance for chemical analysis, Buchner funnel glass filter]
G3: 20–30 μm in pore size
G4: 5–10 μm in pore size

Blue litmus paper  See litmus paper, blue.

Congo red paper  Immerse filter paper in congo red TS, and air-dry.

Glass fiber  See glass wool.

Glass wool  [K 8251, Special class]

Lead acetate paper  See lead (II) acetate paper.

Lead (II) acetate paper  Usually, immerse strips of filter paper, 6 cm × 8 cm in size, in lead (II) acetate TS, drain off the excess liquid, and dry the paper at 100°C, avoiding contact with metals.

Litmus paper, blue  [K 9071, Litmus paper, Blue litmus paper]

Litmus paper, red  [K 9071, Litmus paper, Red litmus paper]

Phosgene test paper  Dissolve 5 g of 4-dimethylaminobenzaldehyde and 5 g of diphenylamine in 100 mL of ethanol (99.5). Immerse a filter paper 5 cm in width in this solution, and allow to dry spontaneously while the paper is suspended in a dark place under clear air. Then cut off the 5-cm portions from the upper side and lower side of the paper, and cut the remaining paper to a length of 7.5 cm.

Preserve in tight, light-resistant containers. Do not use the paper, which has changed to a yellow color.

Potassium iodate-starch paper  Impregnate filter paper with a mixture of equivalent volumes of a solution of potassium iodate (1 in 20) and freshly prepared starch TS, and dry in a clean room.

Storage—Preserve in a glass-stoppered bottle, protected from light and moisture.

Red litmus paper  See litmus paper, red.

Turmeric paper  Macerate 20 g of powdered dried rhizome of Curcuma longa Linné with four 100 mL-portions of cold water, decant the supernatant liquid each time, and discard it. Dry the residue at a temperature not over 100°C. Macerate the dried residue with 100 mL of ethanol (95) for several days, and filter. Immerse filter paper in this ethanol decoction, and allow the ethanol (95) to evaporate spontaneously in clean air.

Sensitivity—Dip a strip of turmeric paper, about 1.5 cm length, in a solution of 1 mg of boric acid in a mixture of 1 mL of hydrochloric acid and 4 mL of water, after 1 minute remove the paper from the liquid, and allow it to dry spontaneously: the yellow color changes to brown. When the strip is moistened with ammonia TS, the color of the strip changes to greenish black.

Zinc iodide-starch paper  Impregnate the filter paper for volumetric analysis with freshly prepared zinc iodide-starch TS, and dry in the clean room. Preserve in a glass-stoppered bottle, protected from light and moisture.

9.44 Standard Particles, etc.

α-Alumina for specific surface area determination
α-Al2O3  Prepared for specific surface area determination.

α-Alumina for thermal analysis  α-Al2O3  Prepared for thermal analysis.

Calibration ball for particle density measurement
Calibration ball with a known volume prepared for measurement of particle density. The volume of the calibration ball must be accurately determined to the nearest 0.001 cm³.

Indium for thermal analysis  In  Prepared for thermal analysis.

Content: not less than 99.99%.

Nickel for thermal analysis  [K 9062 (Nickel). Content: not less than 99.99%]

Standard particles for calibrating light-shielded automatic fine particle counter
Use plastic spherical particles of known size and number.

Sn  [K 8580 (Tin). Content: not less than 99.99%]
Measuring Instruments and Appliances, Thermometers, etc.

9.61 Optical Filters for Wavelength and Transmission Rate Calibration

Use optical filters for wavelength calibration and those for transmission rate calibration shown in Table 9.61-1 and Table 9.61-2, respectively. The optical filters for transmission rate calibration are also used for the calibration of absorbances.

### Table 9.61-1 Optical Filters for Wavelength Calibration

9.62 Measuring Instruments, Appliances

Measuring Instruments are the instruments or machines used for measuring mass or volume in the JP tests, and Appliances are the instruments specified in order to make test conditions as consistent as possible in those tests.

**Balances and weights**

1. Chemical balances—Use balances readable to the extent of 0.1 mg.
2. Semimicrobalances—Use balances readable to the extent of 10 µg.
3. Microbalances—Use balances readable to the extent of 1 µg.
4. Weights—Use calibrated weights.

**Carbon dioxide measuring detector tube** [Gas detector tube measurement system K 0804] Packed with measurement packing for carbon dioxide.

**Carbon monoxide measuring detector tube** [Gas detector tube measurement system K 0804] Packed with measurement packing for carbon monoxide.

**Cassia flask** Use glass-stoppered flasks, shown in Fig. 9.62-1, made of hard glass and having graduation lines of volume on the neck.

**Gas mixer** Use the apparatus, shown in Fig. 9.62-3, made of hard glass.

**Nessler tube** Use colorless, glass-stoppered cylinders 1.0 to 1.5 mm in thickness, shown in Fig. 9.62-2, made of hard glass. The difference of the height of the graduation line of 50 mL from the bottom among cylinders does not exceed 2 mm.

**Sieves** Sieves conform to the specifications in Table 9.62-1. Use the sieve number of nominal size as the designation.

**Volumetric measures** Use volumetric flasks, transfer pipets, push-button micropipets, burets and measuring cylinders conforming to the Japanese Industrial Standard.
9.63 Thermometers

Ordinarily, use calibrated thermometers with an immersion line (rod) or calibrated total immersion mercury-filled thermometers according to the Japanese Industrial Standards. Use the thermometers with the immersion line (rod), shown in Table 9.63-1, for the tests in Congealing Point, Melting Point (Method 1), Boiling Point and Distilling Range.

A: Gas buret (capacity of 100 mL, about 13.7 mm in inside diameter, graduated in 0.2 mL divisions, and graduated in 0.1 mL divisions at the lower, narrow part).

B: Gas buret (capacity of 100 mL, about 4.2 mm in inside diameter at the upper stem with graduation in 0.02 mL division, about 28.5 mm in inside diameter at the lower stem with graduation in 1 mL divisions).

C: (C₁, C₂, C₃ and C₄): Three-way stopcock.

D: Inlet of sample (bent forward at 20 mm in length).

E: Outlet of mixed gas (bent forward at 20 mm in length).

F: Jacket (about 770 mm in length, about 40 mm in outside diameter, almost completely filled with water at room temperature).

G: Rubber pressure tubing, about 4 mm in inside diameter (G₁: about 80 cm in length; G₂ and G₃: about 120 cm in length).

H: Heavy-wall capillary tube (about 1 mm in inside diameter).

K: Receiver.

L₁: Leveling bulb (L₁: filled with about 50 mL of mercury; L₂ and L₃: filled with about 150 mL of mercury).

</table>

To make 1000 g

Melt White Petroleum, Cetanol, White Beeswax, Sorbitan Sesquiole and Lauromacrogol by heating on a water bath, mix and maintain at about 75°C. Add Ethyl Parahydroxybenzoate or Butyl Parahydroxybenzoate to Purified Water or Purified Water in Containers, dissolve by warming at 80°C. Combine both solutions, mix to make emulsion, cool, and stir thoroughly until it congeals.

Description

Absorptive Cream is white in color and is lustrous. It has a slightly characteristic odor.

Containers and storage

Containers—Tight containers.

Acebutolol Hydrochloride

アセプトロール塩酸塩

\[
\text{C}_{18}\text{H}_{28}\text{N}_{2}\text{O}_{4}\cdot\text{HCl}: 372.89
\]

\[\text{N-\{3-Acetyl-4-\{(2RS)-2-hydroxy-3-(1-methylethyl)aminopropoxy\}phenyl\}butanamide monohydrochloride}
\]

[34381-68-5]

Acebutolol Hydrochloride, when dried, contains not less than 98.0% and not more than 102.0% of \(\text{C}_{18}\text{H}_{28}\text{N}_{2}\text{O}_{4}\cdot\text{HCl}\).

Description

Acebutolol Hydrochloride occurs as white to pale yellowish white crystals or crystalline powder.

It is freely soluble in water, in methanol, in ethanol (95) and in acetic acid (100), and practically insoluble in diethyl ether.

A solution of Acebutolol Hydrochloride (1 in 20) shows no optical rotation.

Identification

(1) Determine the absorption spectrum of a solution of Acebutolol Hydrochloride in 0.01 mol/L hydrochloric acid TS (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry \(<2.24\) and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Acebutolol Hydrochloride, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry \(<2.25\), and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) A solution of Acebutolol Hydrochloride (1 in 100) responds to the Qualitative Tests \(<1.00\) for chloride.

Melting point

\(<2.60\) 141 – 145°C

Purity

(1) Heavy metals \(<1.07\)—Proceed with 1.0 g of Acebutolol Hydrochloride according to Method 2, and perform the test. Prepare the control solution with 1.0 mL of Standard Lead Solution (not more than 10 ppm).

(2) Arsenic \(<1.11\)—Prepare the test solution with 1.0 g of Acebutolol Hydrochloride according to Method 3, and perform the test (not more than 2 ppm).

(3) Related substances—Dissolve 40 mg of Acebutolol Hydrochloride in 2 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to make exactly 25 mL, and pipet 1 mL of this solution, add methanol to make exactly 20 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography \(<2.03\). Spot 5 \(\mu\)L each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with the upper layer of a mixture of water, 1-butanol and acetic acid (100) (5:4:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

Loss on drying \(<2.41\) Not more than 1.0% (0.5 g, 105°C, 3 hours).

Residue on ignition \(<2.44\) Not more than 0.2% (1 g).

Assay

Weigh accurately about 0.25 g of Acebutolol Hydrochloride, previously dried, dissolve in 20 mL of acetic acid (100), add 80 mL of acetic anhydride, and titrate \(<2.50\) with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 37.29 mg of \(\text{C}_{18}\text{H}_{28}\text{N}_{2}\text{O}_{4}\cdot\text{HCl}\)

Containers and storage

Containers—Well-closed containers.
Aceglutamide Aluminum

アセグルタミドアルミニウム

\[
\text{C}_{35}\text{H}_{59}\text{Al}_3\text{N}_{10}\text{O}_{24}: 1084.84
\]

Pentakis[(2S)-2-acetylamoino-4-carbamoylbutanoato]tetrahydroxotrialuminium [12607-92-0]

Aceglutamide Aluminum contains not less than 85.4% and not more than 87.6% of aceglutamide \((\text{C}_7\text{H}_7\text{N}_2\text{O}_4: 188.18)\), and not less than 7.0% and not more than 8.0% of aluminum (Al: 26.98), calculated on the dried basis.

**Description** Aceglutamide Aluminum occurs as a white powder, having an astringent bitter taste.

It is freely soluble in water, and practically insoluble in ethanol (99.5).

It dissolves in dilute hydrochloric acid.

It is hygroscopic.

**Identification**

(1) Dissolve 0.03 g each of Aceglutamide Aluminum and Aceglutamide RS in 5 mL of water, and use these solutions as the sample solution and standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.07>. Spot 5 \(\mu\)L each of the sample solution and standard solution on a plate of cellulose for thin-layer chromatography. Develop the plate with a mixture of I-propanol, water and acetic acid (100) (16:8:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly a solution of bromocresol green in ethanol (95) (1 in 100), then spray evenly diluted ammonia solution (28) (1 in 100): the spots from the sample solution and the standard solution show a light yellow and have the same \(R_f\) value.

(2) A solution of Aceglutamide Aluminum in dilute hydrochloric acid (1 in 20) responds to the Qualitative Tests <1.09> for aluminum salt.

**Optical rotation** <2.49> \(\alpha\)D20 \(= -5.5 - 7.5^\circ\) (2 g calculated on the dried basis, water, 50 mL, 100 mm).

**Purity**

(1) Heavy metals <1.07>—Put 1.0 g of Aceglutamide Aluminum in a porcelain crucible, cover the crucible loosely, and heat gently to carbonize. After cooling, add 2 mL of nitric acid and 1 mL of sulfuric acid, heat gently until the white fumes no more evolve, and heat to incinerate at 500 to 600°C. If the incineration is not accomplished, add 2 mL of nitric acid and 1 mL of sulfuric acid, heat in the same manner as above, then ignite at 500 to 600°C to incinerate. After cooling, add 2 mL of hydrochloric acid, proceed with this solution according to Method 2, and perform the test. Prepare the control solution as follows: proceed in the same manner as the preparation of the test solution with the same amount of the reagents, and add 2.0 mL of Standard Lead Solution and water to make 50 mL (not more than 20 ppm).

(2) Arsenic <1.11>—Prepare the test solution with 1.0 g of Aceglutamide Aluminum according to Method 1, and perform the test (not more than 2 ppm).

(3) Related substances—Dissolve 0.10 g of Aceglutamide Aluminum in the mobile phase to make exactly 100 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution (1). Separately, dissolve 10 mg of 2-acetamidoglutaramide in the mobile phase to make exactly 100 mL. Pipet 3 mL of this solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution (2). Perform the test with exactly 20 \(\mu\)L each of the sample solution and standard solutions (1) and (2) as directed under Liquid Chromatography <2.07> according to the following conditions, and determine each peak area by the automatic integration method: the peak area of 2-acetamidoglutaramide from the sample solution is not larger than that from the standard solution (2), the peak areas other than aceglutamide and 2-acetamidoglutaramide from the sample solution are not larger than 10/10 times the peak area of aceglutamide from the sample solution (1), and the total of the peak areas other than aceglutamide and 2-acetamidoglutaramide from the sample solution is not larger than the peak area of aceglutamide from the standard solution (1).

**Operating conditions**—

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay.

Time span of measurement: About 3 times as long as the retention time of aceglutamide.

**System suitability**—

Test for required detection: To exactly 5 mL of the standard solution (1) add the mobile phase to make exactly 50 mL. Confirm that the peak area of aceglutamide obtained from 20 \(\mu\)L of this solution is equivalent to 7 to 13% of that of aceglutamide obtained from 20 \(\mu\)L of the standard solution.

System performance: Proceed as directed in the system suitability in the Assay (1).

System repeatability: When the test is repeated 6 times with 20 \(\mu\)L of the standard solution (1) under the above operating conditions, the relative standard deviation of the peak area of aceglutamide is not more than 2.0%.

**Loss on drying** <2.41> Not more than 5.0% (1 g, 130°C, 5 hours).

**Assay**

(1) Aceglutamide—Weigh accurately about 50 mg of Aceglutamide Aluminum, dissolve in a suitable amount of the mobile phase, add exactly 10 mL of the internal standard solution and the mobile phase to make 50 mL, and use this solution as the sample solution. Separately, weigh accurately about 45 mg of Aceglutamide RS, dissolve in a suitable amount of the mobile phase, add exactly 10 mL of the internal standard solution and the mobile phase to make 50 mL, and use this solution as the standard solution. Perform the test with 10 \(\mu\)L each of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions, and calculate the ratios, \(Q_s\) and \(Q_d\), of the peak area of aceglutamide to that of the internal standard.

\[
\text{Amount (mg) of Aceglutamide (C}_7\text{H}_7\text{N}_2\text{O}_4\text{)} = M_s \times Q_t/Q_s
\]

\(M_s\): Mass of Aceglutamide (C7H7N2O4) sampled

\(Q_t\): peak area of aceglutamide

\(Q_s\): peak area of internal standard
Mₙ: Amount (mg) of Aceglutamide RS

Internal standard solution—A solution of thymine in methanol (1 in 4000).

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 210 nm).
Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 25°C.
Mobile phase: A mixture of diluted perchloric acid (1 in 1000) and methanol (99:1).
Flow rate: Adjust the flow rate so that the retention time of aceglutamide is about 5 minutes.

System suitability—
System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, aceglutamide and the internal standard are eluted in this order with the resolution between these peaks being not less than 11.
System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratios of the peak area of aceglutamide to that of the internal standard is not more than 1.0%.

(2) Aluminum—Weigh accurately about 3.0 g of Aceglutamide Aluminum, add 20 mL of dilute hydrochloric acid, and heat on a water bath for 60 minutes. After cooling, add water to make exactly 200 mL. Pipet 20 mL of this solution, add exactly 25 mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS and 20 mL of acetic acid-ammonium acetate buffer solution, pH 4.8, and boil for 5 minutes. After cooling, add 50 mL of ethanol (95), and titrate <2.5D> with 0.05 mol/L zinc acetate VS until the color of the solution changes from light dark green to light red (indicator: 2 mL of dithizone TS). Perform a blank determination in the same manner.

Each mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS = 1.349 mg of Al

Containers and storage—Containers—Tight containers.

Acemetacin

Acemetacin occurs as a light yellow crystalline powder.

It is soluble in acetone, sparingly soluble in methanol, slightly soluble in ethanol (99.5), and practically insoluble in water.

Identification (1) To 1 mg of Acemetacin add 1 mL of concentrated chromotropic acid TS, and heat in a water bath for 5 minutes: a red-purple color develops.

(2) Determine the absorption spectrum of a solution of Acemetacin in methanol (1 in 50,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(3) Determine the infrared absorption spectrum of Acemetacin as directed in the potassium bromide disk method under Infrared Spectrometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(4) Perform the test with Acemetacin as directed under Flame Coloration Test <1.04> (2): a green color appears.

Melting point <2.6D> 151 – 154°C

Purity (1) Heavy metals <1.07>—Proceed with 1.0 g of Acemetacin according to Method 4, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(2) Related substances—Dissolve 0.40 g of Acemetacin in 10 mL of acetone, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add acetone to make exactly 50 mL. Pipet 1 mL of this solution, add acetone to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin Layer Chromatography <2.03>. Spot 5 μL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin layer chromatography. Develop the plate with a mixture of hexane, 4-methyl-2-pentanone and acetic acid (100) (3:2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): not more than 2 spots other than the principal spot appear from the sample solution, and these spots are not more intense than the spot obtained from the standard solution.

Loss on drying <2.41> Not more than 0.5% (1 g, 105°C, 2 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Weigh accurately about 0.35 g of Acemetacin, previously dried, dissolve in 20 mL of acetone, add 10 mL of water, and then titrate <2.5D> with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination in the same method, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 41.58 mg of C₂₁H₁₈ClNO₆

Containers and storage—Containers—Tight containers.

Acemetacin, when dried, contains not less than 99.0% and not more than 101.0% of C₂₁H₁₈ClNO₆.
Acemetacin Capsules

アセメタシンカプセル

Acemetacin Capsules contain not less than 93.0% and not more than 107.0% of the labeled amount of acemetacin (C$_{21}$H$_{18}$ClNO$_6$). 415.82).

**Method of preparation** Prepare as directed under Capsules, with Acemetacin.

**Identification** To an amount of powdered contents of Acemetacin Capsules, equivalent to 0.1 g of Acemetacin according to the labeled amount, add 100 mL of methanol, shake well, and filter. Take 10 mL of the filtrate, and distil the methanol under reduced pressure. To the residue add 1 mL of methanol, shake well, centrifuge, and use the supernatant liquid as the sample solution. Separately, dissolve 10 mg of acemetacin in 1 mL of methanol, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography (2.03).

Spot 2 µL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of hexane, 4-methyl-2-pentanone and acetic acid (100) (3:2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots obtained from the sample solution and standard solution show the same $R_f$ value.

**Uniformity of dosage units** (6.02) Perform the test according to the following method: it meets the requirement of the Content uniformity test.

Take out the contents of 1 capsule of Acemetacin Capsules, add 40 mL of methanol, shake well, and add methanol to make exactly $V$ mL so that each mL contains about 0.6 mg of acemetacin (C$_{21}$H$_{18}$ClNO$_6$). Filter this solution, discard the first 10 mL of the filtrate, pipet 5 mL of the subsequent filtrate, add exactly 2 mL of the internal standard solution, add methanol to make 50 mL, and use this solution as the sample solution. Proceed as directed in the Assay.

**Dissolution** (6.10) When the test is performed at 50 revolutions per minute according to the Paddle method using the sinker, using 900 mL of 2nd fluid for dissolution test as the dissolution medium, the dissolution rate in 30 minutes of Acemetacin Capsules is not less than 70%.

Start the test with 1 capsule of Acemetacin Capsules, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.45 µm. Discard the first 10 mL of the filtrate, pipet $V$ mL of the subsequent filtrate, add the dissolution medium to make exactly $V$ mL so that each mL contains about 33 µg of acemetacin (C$_{21}$H$_{18}$ClNO$_6$) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 17 mg of acemetacin for assay, previously dried at 105°C for 2 hours, dissolve in the dissolution medium to make exactly 100 mL. Pipet 4 mL of this solution, add the dissolution medium to make exactly 20 mL, and use this solution as the standard solution. Determine the absorbances, $A_T$ and $A_S$, of the sample solution and standard solution at 319 nm as directed under Ultraviolet-visible Spectrophotometry (2.24).

Dissolution rate (%) with respect to the labeled amount of acemetacin (C$_{21}$H$_{18}$ClNO$_6$) = $M_S \times A_T / A_S \times V / V \times 1 / C \times 180$

$M_S$: Amount (mg) of acemetacin for assay

C: Labeled amount (mg) of acemetacin (C$_{21}$H$_{18}$ClNO$_6$) in 1 capsule

**Assay** Take out the contents of no less than 20 Acemetacin Capsules, weigh accurately the mass of the contents, and powder. Weigh accurately a portion of the powder, equivalent to about 30 mg of acemetacin (C$_{21}$H$_{18}$ClNO$_6$), add 40 mL of methanol, shake well, and add methanol to make exactly 50 mL. Filter this solution, discard the first 10 mL of the filtrate, pipet 5 mL of the subsequent filtrate, add exactly 2 mL of the internal standard solution, add methanol to make 50 mL, and use this solution as the sample solution. Separately, weigh accurately about 30 mg of acemetacin for assay, previously dried at 105°C for 2 hours, and dissolve in methanol to make exactly 50 mL. Pipet 5 mL of this solution, add exactly 2 mL of the internal standard solution, add methanol to make 50 mL, and use this solution as the standard solution. Perform the test with 20 µL each of the sample solution and standard solution as directed under Liquid Chromatography (2.01) according to the following conditions, and calculate the ratios, $Q_T$ and $Q_S$, of the peak area of acemetacin to that of the internal standard.

Amount (mg) of acemetacin (C$_{21}$H$_{18}$ClNO$_6$) = $M_S \times Q_T / Q_S$

$M_S$: Amount (mg) of acemetacin for assay

**Internal standard solution**—A solution of hexyl parahydroxybenzoate in methanol (1 in 1000).

**Operating conditions**—

Detector: An ultraviolet absorption photometer (wavelength 254 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 µm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: To 6 g of acetic acid (100) add water to make 1000 mL, and adjust the pH to 3.2 with a solution of 1.36 g of sodium acetate trihydrate in 100 mL of water. To 200 mL of this solution add 300 mL of acetonitrile.

Flow rate: Adjust the flow rate so that the retention time of acemetacin is about 7 minutes.

**System suitability**—

System performance: Dissolve 75 mg of acemetacin and 75 mg of indometacin in 50 mL of methanol. To 2 mL of this solution add 2 mL of the internal standard solution, and add methanol to make 50 mL. When the procedure is run with 20 µL of this solution under the above operating conditions, acemetacin, indometacin and the internal standard are eluted in this order with the resolutions between the peaks of acemetacin and indometacin and between the peaks of in-
dometacin and the internal standard being not less than 3, respectively.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of acemetacin to that of the internal standard is not more than 1.0%.

Containers and storage  Containers—Tight containers.

Acemetacin Tablets

アセメタシン錠

Acemetacin Tablets contain not less than 93.0% and not more than 107.0% of the labeled amount of acemetacin (C₂₁H₁₈ClNO₆: 415.82).

Method of preparation  Prepare as directed under Tablets, with Acemetacin.

Identification  To a quantity of powdered Acemetacin Tablets, equivalent to 0.1 g of Acemetacin according to the labeled amount, add 100 mL of methanol, shake well, and filter. Take 10 mL of the filtrate, and distill the methanol under reduced pressure. Dissolve the residue in 1 mL of methanol, centrifuge, and use the supernatant liquid as the sample solution. Separately, dissolve 10 mg of acemetacin in 1 mL of methanol, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.07>. Spot 2 μL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of hexane, 4-methyl-2-pentanone and acetic acid (100) (3:2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots obtained from the sample solution and standard solution show the same Rf value.

Uniformity of dosage units <6.02>  Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Acemetacin Tablets add 3 mL of water, and shake until the tablet is disintegrated. Add 15 mL of methanol, shake for 20 minutes, and add methanol to make exactly 50 mL so that each mL contains about 33 μg of acemetacin (C₂₁H₁₈ClNO₆). Centrifuge this solution, filter the supernatant liquid, discard the first 10 mL of the filtrate, pipet 2 mL of the subsequent filtrate, and use this solution as the sample solution. Proceed as directed in the Assay.

\[
M_S = \frac{M_T \times A_T / A_S \times V/V \times 1/C \times 100}{M_S}
\]

M₅: Amount (mg) of acemetacin for assay

Internal standard solution—A solution of hexyl parahydroxybenzoate in methanol (1 in 250).

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength 254 nm).
Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Mobile phase: To 6 g of acetic acid (100) add water to make 1000 mL, and adjust the pH to 3.2 with a solution of

medium, the dissolution rate in 45 minutes of Acemetacin Tablets is not less than 80%.

Start the test with 1 tablet of Acemetacin Tablets, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.45 μm. Discard the first 10 mL of the filtrate, pipet V mL of the subsequent filtrate, add the dissolution medium to make exactly V mL so that each mL contains about 33 μg of acemetacin (C₂₁H₁₈ClNO₆) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 17 mg of acemetacin for assay, previously dried at 105°C for 2 hours, dissolve in the dissolution medium to make exactly 100 mL. Pipet 4 mL of this solution, add the dissolution medium to make exactly 20 mL, and use this solution as the standard solution. Determine the absorbances, A₇₅ and A₃₁₉ of the sample solution and standard solution at 319 nm as directed under Ultraviolet-visible Spectrophotometry <2.24>.

Dissolution rate (%) with respect to the labeled amount of acemetacin (C₂₁H₁₈ClNO₆)

\[
M_S = \frac{M_T \times A_T / A_S \times V/V \times 1/C \times 100}{M_S}
\]

M₅: Amount (mg) of acemetacin for assay

C: Labeled amount (mg) of acemetacin (C₂₁H₁₈ClNO₆) in 1 tablet

Assay  Weigh accurately the mass of not less than 20 Acemetacin Tablets, and powder. Weigh accurately a portion of the powder, equivalent to about 0.6 g of acemetacin (C₂₁H₁₈ClNO₆), add 120 mL of methanol, shake for 20 minutes, and add methanol to make exactly 200 mL. Centrifuge this solution, filter the supernatant liquid, discard the first 10 mL of the filtrate, pipet 2 mL of the subsequent filtrate, and use this solution as the sample solution. Separately, weigh accurately about 30 mg of acemetacin for assay, previously dried at 105°C for 2 hours, and dissolve in methanol to make exactly 25 mL. Pipet 5 mL of this solution, add exactly 1 mL of the internal standard solution, add methanol to make 50 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions, and calculate the ratios, Q₇₅ and Q₃₁₉, of the peak area of acemetacin to that of the internal standard.

Amount (mg) of acemetacin (C₂₁H₁₈ClNO₆)

\[
M_S = \frac{M_T \times A_T / A_S \times V/V \times 1/C \times 100}{M_S}
\]

M₅: Amount (mg) of acemetacin for assay

Internal standard solution—A solution of hexyl parahydroxybenzoate in methanol (1 in 250).

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength 254 nm).
Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Mobile phase: To 6 g of acetic acid (100) add water to make 1000 mL, and adjust the pH to 3.2 with a solution of
1.36 g of sodium acetate trihydrate in 100 mL of water. To 200 mL of this solution add 300 mL of acetonitrile.

Flow rate: Adjust the flow rate so that the retention time of acetaminophen is about 7 minutes.

System suitability—
System performance: Dissolve 75 mg of acetaminophen and 75 mg of indomethacin in 50 mL of methanol. To 4 mL of this solution add 1 mL of the internal standard solution, and add methanol to make 50 mL. When the procedure is run with 10 μL of this solution under the above operating conditions, acetaminophen, indomethacin and the internal standard are eluted in this order with the resolutions between the peaks of acetaminophen and indomethacin and between the peaks of indomethacin and the internal standard being not less than 3, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of acetaminophen to that of the internal standard is not more than 1.0%.

Containers and storage—Containers—Tight containers.

Acetaminophen

Paracetamol

Acetaminophen, when dried, contains not less than 98.0% of C₇H₉NO₂.

Description Acetaminophen occurs as white crystals or crystalline powder.

It is freely soluble in methanol and in ethanol (95), sparingly soluble in water, and very slightly, soluble in diethyl ether.

It dissolves in sodium hydroxide TS.

Identification Determine the infrared absorption spectra of Acetaminophen, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum or the spectrum of dried Acetaminophen RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

Melting point <2.60> 169 – 172°C

Purity (1) Chloride <1.03>—Dissolve 4.0 g of Acetaminophen in 100 mL of water by heating, cool with shaking in ice water, allow to stand until ordinary temperature is attained, add water to make 100 mL, and filter. To 25 mL of the filtrate add 6 mL of dilute nitric acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 0.40 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.014%).

(2) Sulfate <1.14>—To 25 mL of the filtrate obtained in (1) add 1 mL of dilute hydrochloric acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 0.40 mL of 0.005 mol/L sulfuric acid VS (not more than 0.019%).

(3) Heavy metals <1.07>—Proceed with 2.0 g of Acetaminophen according to Method 4, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(4) Arsenic <1.11>—Prepare the test solution with 1.0 g of Acetaminophen according to Method 3, and perform the test (not more than 2 ppm).

(5) Related substances—Dissolve 50 mg of Acetaminophen in 1 mL of methanol, add the mobile phase to make 200 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the total area of all peaks other than the peak area of acemetacin from the sample solution is not larger than the peak area of acetaminophen from the standard solution.

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 225 nm).

Column: A stainless steel column about 4 mm in inside diameter and about 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of 0.05 mol/L potassium dihydrogenphosphate, pH 4.7 and methanol (4:1)

Flow rate: Adjust the flow rate so that the retention time of acetaminophen is about 5 minutes.

Selection of column: Dissolve 0.01 g each of Acetaminophen and p-aminophenol in 1 mL of methanol, add the mobile phase to make 50 mL, to 1 mL of this solution add the mobile phase to make 10 mL. Proceed with 10 μL of this solution under the above operating conditions, and calculate the resolution. Use a column giving elution of p-aminophenol and acetaminophen in this order with the resolution between these peaks being not less than 7.

Detection sensitivity: Adjust the detection sensitivity so that the peak height of acetaminophen obtained from 10 μL of the standard solution is about 15% of the full scale.

Time span of measurement: About 6 times as long as the retention time of acetaminophen beginning after the solvent peak.

Loss on drying <2.41> Not more than 0.3% (0.5 g, 105°C, 2 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Weigh accurately about 20 mg each of Acetaminophen and Acetaminophen RS, previously dried, dissolve in 2 mL of methanol, and add water to make exactly 100 mL. Pipet 3 mL each of these solutions, add water to make exactly 100 mL, and use these solutions as the sample solution and standard solution, respectively. Determine the absor-
Acetazolamide

\[
\text{C}_4\text{H}_6\text{N}_4\text{O}_3\text{S}_2: 222.25
\]

\(\text{N}-(5\text{-Sulfamoyl-1,3,4-thiadiazol-2-yl})\text{acetamide} [59-66-5]\)

Acetazolamide contains not less than 98.0% and not more than 102.0% of \(\text{C}_4\text{H}_6\text{N}_4\text{O}_3\text{S}_2\), calculated on the dried basis.

**Description** Acetazolamide occurs as a white to pale yellowish white, crystalline powder. It is odorless, and has a slight bitter taste.

It is slightly soluble in ethanol (95), very slightly soluble in water, and practically insoluble in diethyl ether.

**Melting point:** About 255°C (with decomposition).

**Identification (1)** To 0.1 g of Acetazolamide add 5 mL of sodium hydroxide TS, then add 5 mL of a solution of 0.1 g of hydroxyaminomethylicloride and 0.05 g of copper (II) sulfate pentahydrate in 10 mL of water: a light yellow color develops. Then heat this solution for 5 minutes: a deep yellow color is produced gradually.

(2) To 0.02 g of Acetazolamide add 2 mL of dilute hydrochloric acid, boil for 10 minutes, cool, and add 8 mL of water: this solution responds to the Qualitative Tests \(<1.09\) for primary aromatic amines.

(3) To 0.2 g of Acetazolamide add 0.5 g of granulated zinc and 5 mL of dilute hydrochloric acid (1 in 2): the gas evolved darkens moistened lead (II) acetate paper.

**Purity (1)** Clarity and color of solution—Dissolve 1.0 g of Acetazolamide in 10 mL of sodium hydroxide TS: the solution is clear and colorless to pale yellow.

(2) Chloride \(<1.07\)—To 1.5 g of Acetazolamide add 75 mL of water, and warm at 70°C for 20 minutes with occasional shaking. After cooling, filter, and to 25 mL of the filtrate add 6 mL of dilute nitric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 0.20 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.038%).

(3) Sulfate \(<1.14\)—To 25 mL of the filtrate obtained in (2) add 1 mL of dilute hydrochloric acid and water to make 50 mL. Prepare the test solution with 0.40 mL of 0.005 mol/L sulfuric acid VS (not more than 0.038%).

(4) Heavy metals \(<1.07\)—Proceed with 1.0 g of Acetzolamide according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(5) Silver-reducing substances—Wet 5 g of Acetazolamide with 5 mL of aldehyde-free ethanol, and add 125 mL of water, 10 mL of nitric acid and exactly 5 mL of 0.1 mol/L silver nitrate VS. Stir for 30 minutes by protecting from light, filter through a glass filter (G3), and wash the residue on the glass filter with two 10-mL portions of water. Combine the filtrate with the washings, to the solution add 5 mL of ferric ammonium sulfates, and titrate \(<2.50\) with 0.1 mol/L ammonium thiocyanate VS: not less than 4.8 mL of 0.1 mol/L ammonium thiocyanate VS is consumed.

**Loss on drying** \(<2.41\) Not more than 0.5% (0.5 g, 105°C, 3 hours).

**Residue on ignition** \(<2.44\) Not more than 0.1% (0.5 g).

**Assay** Weigh accurately about 0.15 g of Acetazolamide, and dissolve in 400 mL of water in a water bath by heating. After cooling, add water to make exactly 1000 mL. Pipet 5 mL of the solution, add 10 mL of 1 mol/L hydrochloric acid TS, and then add water to make exactly 100 mL. Determine the absorbance \(A\) of this solution at the wavelength of maximum absorption at about 265 nm as directed under Ultraviolet-visible Spectrophotometry \(<2.24\).

Amount (mg) of \(\text{C}_4\text{H}_6\text{N}_4\text{O}_3\text{S}_2\) = \(A/474 \times 200,000\)

**Containers and storage** Containers—Well-closed containers.

**Storage**—Light-resistant.

**Acetic Acid**

酢酸

Acetic Acid contains not less than 30.0 w/v% and not more than 32.0 w/v% of \(\text{C}_2\text{H}_4\text{O}_2\): 60.05.

**Description** Acetic Acid is a clear, colorless liquid. It has a pungent, characteristic odor and an acid taste.

It is miscible with water, with ethanol (95) and with glycerin.

**Specific gravity** \(d_2^{20}:\) about 1.04

**Identification** Acetic Acid changes blue litmus paper to red, and responds to the Qualitative Tests \(<1.09\) for acetate.

**Purity (1)** Chloride—To 20 mL of Acetic Acid add 40 mL of water, and use this solution as the sample solution. To 10 mL of the sample solution add 5 drops of silver nitrate TS: no opalescence is produced.

(2) Sulfate—To 10 mL of the sample solution obtained in (1) add 1 mL of barium chloride TS: no turbidity is produced.

(3) Heavy metals \(<1.07\)—Evaporate 10 mL of Acetic Acid on a water bath to dryness, and to the residue add 2 mL of dilute acetic acid and water to make 50 mL. Perform the test with this solution as the test solution. Prepare the control solution with 3.0 mL of Standard Lead Solution by adding 2 mL of dilute acetic acid and water to make 50 mL (not
more than 3 ppm).

(4) Potassium permanganate-reducing substances—To 20 mL of the sample solution obtained in (1) add 0.02 mol/L potassium permanganate VS: the red color does not disappear within 30 minutes.

(5) Non-volatile residue—Evaporate 30 mL of Acetic Acid on a water bath to dryness, and dry at 105°C for 1 hour: the mass of the residue is not more than 1.0 mg.

**Assay** Measure exactly 5 mL of Acetic Acid, add 30 mL of water, and titrate 2.50 μL with 1 mol/L sodium hydroxide VS (indicator: 2 drops of phenolphthalein TS).

Each mL of 1 mol/L sodium hydroxide VS = 60.05 mg of C₂H₄O₂

**Containers and storage** Containers—Tight containers.

### Glacial Acetic Acid

**氷酢酸**

C₂H₄O₂: 60.05

**Acetic acid**

[C₆H₄O₂]

**Description** Glacial Acetic Acid is a clear, colorless, volatile liquid, or colorless or white, crystalline masses. It has a pungent, characteristic odor.

It is miscible with water, with ethanol (95) and with diethyl ether.

Boiling point: about 118°C

Specific gravity d₂₀: about 1.049

**Identification** A solution of Glacial Acetic Acid (1 in 3) changes blue litmus paper to red, and responds to the Qualitative Tests (1.090) for acetate.

**Congealing point** 2.42°C Not below 14.5°C.

**Purity (1)** Chloride—To 10 mL of Glacial Acetic Acid add water to make 100 mL, and use this solution as the sample solution. To 10 mL of the sample solution add 5 drops of silver nitrate TS: no turbidity is produced.

(2) Sulfate—To 10 mL of the sample solution obtained in (1) add 1 mL of barium chloride TS: no turbidity is produced.

(3) Heavy metals <1.07μg—Evaporate 2.0 mL of Glacial Acetic Acid on a water bath to dryness. Dissolve the residue in 2 mL of dilute acetic acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 2.0 mL of Standard Lead Solution by adding 2.0 mL of dilute acetic acid and water to make 50 mL (not more than 10 ppm).

(4) Potassium permanganate-reducing substances—To 20 mL of the sample solution obtained in (1) add 0.10 mL of 0.1 mol/L potassium permanganate VS: the red color does not disappear within 30 minutes.

(5) Non-volatile residue—Evaporate 10 mL of Glacial Acetic Acid on a water bath to dryness, and dry at 105°C for 1 hour: the mass of the residue is not more than 1.0 mg.

**Assay** Place 10 mL of water in a glass-stoppered flask, and weigh accurately. Add about 1.5 g of Glacial Acetic Acid, weigh accurately again, then add 30 mL of water, and titrate 2.50 μL with 1 mol/L sodium hydroxide VS (indicator: 2 drops of phenolphthalein TS).

Each mL of 1 mol/L sodium hydroxide VS = 60.05 mg of C₂H₄O₂

**Containers and storage** Containers—Tight containers.

### Acetohexamide

**アセトヘキサミド**

C₁₅H₂₀N₂O₄S: 324.40

4-Acetyl-N-(cyclohexylcarbamoyl)benzenesulfonamide [968-81-0]

Acetohexamide, when dried, contains not less than 98.0% and not more than 101.0% of C₁₅H₂₀N₂O₄S.

**Description** Acetohexamide occurs as a white to yellowish white powder.

It is freely soluble in N,N-dimethylformamide, sparingly soluble in acetone, slightly soluble in methanol and in ethanol (99.5), and practically insoluble in water.

Melting point: about 185°C (with decomposition).

**Identification** (1) Dissolve 0.10 g of Acetohexamide in 100 mL of methanol. To 5 mL of the solution add 20 mL of 0.5 mol/L hydrochloric acid TS and 75 mL of methanol, and use the solution as the sample solution (1). Determine the absorption spectrum of the sample solution (1) as directed under Ultraviolet-visible Spectrophotometry (2.24), using methanol as the blank, and compare the spectrum with the Reference Spectrum 1: both spectra exhibit similar intensities of absorption at the same wavelengths. Separately, to exactly 10 mL of the sample solution (1) add methanol to make exactly 50 mL, and use the solution as the sample solution (2). Determine the absorption spectrum of the sample solution (2) as directed under Ultraviolet-visible Spectrophotometry (2.24), using methanol as the blank, and compare the spectrum with the Reference Spectrum 2: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Acetohexamide, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry (2.25), and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Purity (1)** Chloride <1.0μg—Dissolve 1.5 g of Acetohexamide in 40 mL of N,N-dimethylformamide, add 6 mL of dilute nitric acid and N,N-dimethylformamide to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: to 0.45 mL of 0.01 mol/L hydrochloric acid VS add 6 mL of dilute nitric acid and N,N-dimethylformamide to make 50 mL (not more than
(2) Sulfate—Dissolve 2.0 g of Acetohexamide in 40 mL of N,N-dimethylformamide, and add 1 mL of dilute hydrochloric acid and N,N-dimethylformamide to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: to 0.40 mL of 0.005 mol/L sulfuric acid VS add 1 mL of dilute hydrochloric acid and N,N-dimethylformamide to make 50 mL (not more than 0.010%).

(3) Heavy metals—Proceed with 1.0 g of Acetohexamide according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(4) Related substances (i) Cyclohexylamine—Dissolve exactly 1.0 g of Acetohexamide in exactly 30 mL of 0.5 mol/L sodium hydroxide TS, add exactly 5 mL of hexane, shake vigorously for 60 minutes, allow to stand for 5 minutes, and use the upper layer as the sample solution. Separately, dissolve exactly 50 mg of cyclohexylamine in 0.5 mol/L sodium hydroxide TS to make exactly 50 mL. Pipet 2 mL of this solution, and add 0.5 mol/L sodium hydroxide TS to make exactly 300 mL. Pipet 30 mL of this solution, add exactly 5 mL of hexane, shake vigorously for 60 minutes, allow to stand for 5 minutes, and use the upper layer as the standard solution. Perform the test with exactly 2 μL each of the sample solution and standard solution as directed under Gas Chromatography according to the following conditions, and determine the peak area of cyclohexylamine by the automatic integration method: the peak area of cyclohexylamine is not more than that with the standard solution.

Operating conditions—
Detector: A hydrogen flame-ionization detector.
Column: A fused-silica column 0.53 mm in inside diameter and 30 m in length, coated the inner surface with methylsilicone polymer for gas chromatography 1.5 μm in thickness.
Column temperature: A constant temperature of about 90°C.
Injection port temperature: A constant temperature of about 150°C.
Detector temperature: A constant temperature of about 210°C.
Carrier gas: Helium
Flow rate: Adjust the flow rate so that the retention time of cyclohexylamine is about 4 minutes.
Split ratio: 1:1

System suitability—
System performance: When the procedure is run with 50 μL of the standard solution under the above operating conditions, the number of theoretical plates of the peak of diclohexylurea is not less than 10,000.
System repeatability: When the test is repeated 6 times with 50 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of cyclohexylamine is not more than 5%.

(ii) Dicyclohexylurea—Dissolve exactly 1.0 g of Acetohexamide in exactly 10 mL of 0.5 mol/L sodium hydroxide TS, add exactly 20 mL of methanol, shake, then add exactly 5 mL of dilute hydrochloric acid (1 in 10), shake vigorously for 15 minutes, and centrifuge. Filter 10 mL or more of the supernatant liquid through a membrane filter with pore size of not larger than 0.5 μm. Discard the first 5 mL of the filtrate, and use the subsequent filtrate as the sample solution. Separately, dissolve exactly 50 mg of dicyclohexylurea in methanol to make exactly 100 mL. Pipet 2 mL of this solution, and add methanol to make exactly 100 mL. Pipet 20 mL of this solution, add exactly 10 mL of 0.5 mol/L sodium hydroxide TS, shake, then add exactly 5 mL of dilute hydrochloric acid (1 in 10), shake, and use this solution as the standard solution. Perform the test with exactly 50 μL each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and determine the peak area of dicyclohexylurea by the automatic integration method: the peak area of dicyclohexylurea is not more than that with the standard solution.

Related substances (iii) Other related substances—Dissolve 0.10 g of Acetohexamide in 10 mL of acetone, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add acetone to make exactly 20 mL. Pipet two 1 mL portions of this solution, add acetone to make exactly 10 mL and 25 mL, respectively, and use these solutions as the standard solution (1) and the standard solution (2). Perform the test with these solutions as directed under Thin-layer Chromatography (3) Spot 10 μL each of the sample solution and standard solutions (1) and (2) on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of ethyl acetate, methanol, ammonia solution (28) and cyclohexane (6:2:1:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots other than the principal spot from the sample solution are not more intense than spot from the standard solution (1), and the number of them which are more intense than the spot from the standard solution (2) is not more than 4.

Loss on drying—Not more than 1.0% (1 g, 105°C, 4 hours).

Residue on ignition—Not more than 0.1% (1 g).

Assay—Weigh accurately about 0.3 g of Acetohexamide, previously dried, dissolve in 30 mL of N,N-dimethylfor-
Acetylcholine Chloride for Injection / Official Monographs

Acetylcholine Chloride for Injection

Acetylcholine Chloride for Injection is a preparation for injection which is dissolved before use.

It contains not less than 98.0% and not more than 102.0% of acetylcholine chloride (C₇H₁₆ClNO₂), and not less than 19.3% and not more than 19.8% of chlorine (Cl: 35.45), calculated on the dried basis.

It contains not less than 93.0% and not more than 107.0% of the labeled amount of acetylcholine chloride (C₇H₁₆ClNO₂).

Method of preparation

Prepare as directed under Injection.

Description

Acetylcholine Chloride for Injection occurs as white crystals or crystalline powder.

It is very soluble in water, and freely soluble in ethanol (95).

It is extremely hygroscopic.

Identification

(1) Determine the infrared absorption spectrum of Acetylcholine Chloride for Injection, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(2) A solution of Acetylcholine Chloride for Injection (1 in 10) responds to the Qualitative Tests <1.09> (2) for chloride.

Melting point

149 – 152°C. Seal Acetylcholine Chloride for Injection in a capillary tube for melting point immediately after drying both of the sample and the tube at 105°C for 3 hours, and determine the melting point.

Purity

(1) Clarity and color of solution—Dissolve 1.0 g of Acetylcholine Chloride for Injection in 10 mL of water: the solution is clear and colorless.

(2) Acidity—Dissolve 0.10 g of Acetylcholine Chloride for Injection in 10 mL of freshly boiled and cooled water, and add 1 drop of bromothymol blue TS, and 0.30 mL of 0.01 mol/L sodium hydroxide VS: the solution is blue in color.

(3) Heavy metals <1.07>—Proceed with 2.0 g of Acetylcholine Chloride for Injection according to Method 1, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

Loss on drying <2.41> Not more than 1.0% (1 g, 105°C, 3 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Uniformity of dosage units <6.02> It meets the requirement of the Mass variation test.

Foreign insoluble matter <6.05> Perform the test according to Method 2: it meets the requirement.

Insoluble particulate matter <6.07> It meets the requirement.

Sterility <4.06> Perform the test according to the Membrane filtration method: it meets the requirement.

Assay

(1) Acetylcholine chloride—Weigh accurately the contents of not less than 10 Acetylcholine Chloride for Injections. Weigh accurately about 0.5 g of the contents, dissolve in 15 mL of water, then add exactly 40 mL of 0.1 mol/L sodium hydroxide VS, stopper loosely, and heat on a water bath for 30 minutes. Cool quickly, and titrate <2.50> the excess sodium hydroxide with 0.05 mol/L sulfuric acid VS (indicator: 3 drops of phenolphthalein TS). Perform a blank determination.

Each mL of 0.1 mol/L sodium hydroxide VS = 18.17 mg of C₇H₁₆ClNO₂

(2) Chlorine—Titrate <2.50> the solution, which has been titrated in (1), with 0.1 mol/L silver nitrate VS (indicator: 3 drops of fluorescein sodium TS).

Each mL of 0.1 mol/L silver nitrate VS = 3.545 mg of Cl

Containers and storage

Containers—Well-closed containers.

Containers and storage

Containers—Hermetic containers.

Acetylcysteine

Acetylcysteine occurs as white crystals or crystalline powder.

It is freely soluble in water and in ethanol (99.5).

It dissolves in sodium hydroxide TS.

Acetylcysteine contains not less than 99.0% and not more than 101.0% of C₅H₉NO₃S, calculated on the dried basis.

Description

Acetylcysteine occurs as white, crystals or crystalline powder.

It is very soluble in water, and in ethanol (99.5).

It is extremely hygroscopic.

Identification

(1) Determine the infrared absorption spectrum of Acetylcysteine as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and com-
pare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Optical rotation** \( \angle \alpha.D. +21.0° \pm 27.0° \) — Weigh accurately an amount of Acetylcysteine, equivalent to about 2.5 g calculated on the dried basis, and dissolve with 2 mL of a solution of disodium dihydrogen ethylenediamine tetraacetate dihydrate (1 in 100) and 15 mL of a solution of sodium hydroxide (1 in 25). To this solution add a solution, prepared by adjusting the pH to 7.0 of 500 mL of a solution of potassium dihydrogen phosphate (17 in 125) with sodium hydroxide TS and adding water to make 1000 mL, to make exactly 50 mL. Determine the optical rotation of this solution using a 100-mm cell.

**Melting point** \( \angle 2.49° \) — 107–111°C

**Purity** (1) Chloride \( \angle 1.03° \) — Dissolve 0.40 g of Acetylcysteine in 25 mL of sodium hydroxide TS, add 4 mL of hydrogen peroxide (30%), heat in a water bath for 45 minutes, and cool. Then add 5 mL of nitric acid, add water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 0.45 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.040%).

(2) Sulfate \( \angle 1.14° \) — Perform the test with 0.8 g of Acetylcysteine. Prepare the control solution with 0.50 mL of 0.005 mol/L sulfuric acid VS (not more than 0.030%).

(3) Ammonium \( \angle 1.02° \) — Perform the test with 0.10 g of Acetylcysteine, using the dilution under reduced pressure. Prepare the control solution with 2.0 mL of Standard Ammonium Solution (not more than 0.02%).

(4) Heavy metals \( \angle 1.07° \) — Dissolve 1.0 g of Acetylcysteine in 40 mL of water, add 3 mL of sodium hydroxide TS, 2 mL of dilute acetic acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution as follows: To 1.0 mL of Standard Lead Solution add 2 mL of dilute acetic acid and water to make 50 mL (not more than 10 ppm).

(5) Iron \( \angle 1.10° \) — Prepare the test solution with 1.0 g of Acetylcysteine according to Method 1, and perform the test according to Method A. Prepare the control solution with 1.0 mL of Standard Iron Solution (not more than 10 ppm).

(6) Related substances — Dissolve 50 mg of Acetylcysteine in 25 mL of the mobile phase, and use this solution as the sample solution. The sample solution is prepared before using. Perform the test with 10 μL of the sample solution as directed under Liquid Chromatography \( \angle 2.01° \) according to the following conditions, determine each peak area by the automatic integration method, and calculate their amounts by the area percentage method: the area of the peak other than acetylcysteine is not more than 0.3%, and the total area of the peak other than acetylcysteine is not more than 0.6%.

**Operating conditions** —

Detector: An ultraviolet absorption photometer (wave-length: 220 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of diluted phosphoric acid (1 in 2500) and acetonitrile (19:1).

Flow rate: Adjust the flow rate so that the retention time of acetylcysteine is about 7 minutes.

Time span of measurement: About 4 times as long as the retention time of acetylcysteine, beginning after the solvent peak.

System suitability —

Test for required detectability: To 1 mL of the sample solution add the mobile phase to make 10 mL. To 1 mL of this solution, add the mobile phase to make 20 mL, and use this solution as the solution for system suitability test. Pipet 5 mL of the solution for system suitability test, and add the mobile phase to make exactly 25 mL. Confirm that the peak area of acetylcysteine obtained with 10 μL of this solution is equivalent to 15 to 25% of that with 10 μL of the solution for system suitability test.

System performance: When the procedure is run with 10 μL of the solution for system suitability test under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of acetylcysteine are not less than 15,000 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the solution for system suitability test under the above operating conditions, the relative standard deviation of the peak area of acetylcysteine is not more than 2.0%.

(7) Residual solvent — Being specified separately.

**Loss on drying** \( \angle 2.41° \) — Not more than 0.5% (1 g, 80°C, 3 hours).

**Residue on ignition** \( \angle 2.44° \) — Not more than 0.3% (1 g).

**Assay** — Weigh accurately about 0.2 g of Acetylcysteine, place it in a stoppered flask, dissolve in 20 mL of water, add 4 g of potassium iodide and 5 mL of dilute hydrochloric acid, then add exactly 25 mL of 0.05 mol/L iodine VS, stopper tightly, allow to stand for 20 minutes in an ice cold water in the dark, and titrate \( \angle 2.50° \) the excess of iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 1 mL of starch TS). Perform a blank determination in the same manner.

Each mL of 0.05 mol/L iodine VS = 16.32 mg of C₇H₇NO₅S

**Containers and storage** — Containers — Tight containers.

**Aciclovir**

Aciclovir occurs as a white to pale yellowish
white crystalline powder.

It is slightly soluble in water and very slightly soluble in ethanol (99.5).

It dissolves in 0.1 mol/L hydrochloric acid TS and in dilute sodium hydroxide TS.

Identification (1) Determine the absorption spectrum of a solution of Aciclovir in 0.1 mol/L hydrochloric acid TS (1 in 10,000) as directed under Ultraviolet-visible Spectrophotometry <2.2ζ>, and compare the spectrum with the Reference Spectrum or the spectrum of Aciclovir RS: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Aciclovir as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.2ζ>, and compare the spectrum with the Reference Spectrum or the spectrum of Aciclovir RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

Purity (1) Clarity and color of solution—Dissolve 0.5 g of Aciclovir in 20 mL of dilute sodium hydroxide TS: the solution is clear and is not more colored than the following control solution.

Control solution: To 2.5 mL of Matching Fluid for Color F add diluted dilute hydrochloric acid (1 in 10) to make 100 mL.

(2) Heavy metals <1.0ζ>—Proceed with 1.0 g of Aciclovir according to Method 2, and perform the test. Prepare the control solution with 1.0 mL of Standard Lead Solution (not more than 10 ppm).

(3) Related substances—Use the sample solution obtained in the Assay as the sample solution. Separately, weigh accurately about 25 mg of guanine, dissolve in 50 mL of dilute sodium hydroxide TS, and add the mobile phase to make exactly 100 mL. Pipet 2 mL of this solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.0ζ>, according to the following conditions, and determine the peak areas, A<sub>T</sub> and A<sub>S</sub>, of aciclovir.

Amount (mg) of C<sub>8</sub>H<sub>11</sub>N<sub>5</sub>O<sub>3</sub> = M<sub>S</sub> × A<sub>T</sub>/A<sub>S</sub>

M<sub>S</sub>: Amount (mg) of Aciclovir RS, calculated on the anhydrous basis

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 10 cm in length, packed with octadecylsilylated silica gel for liquid chromatography (3 μm in particle diameter).

Column temperature: A constant temperature of about 20°C.

Mobile phase: Dissolve 1.0 g of sodium 1-decanesulfonate and 6.0 g of sodium dihydrogen phosphate dihydrate in 1000 mL of water, and adjust the pH to 3.0 with phosphoric acid. To this solution add 40 mL of acetonitrile.

Flow rate: Adjust the flow rate so that the retention time of aciclovir is about 3 minutes.

System suitability—

System performance: Dissolve 0.1 g of Aciclovir in 5 mL of dilute sodium hydroxide TS, add 2 mL of a solution of guanine in dilute sodium hydroxide TS (1 in 4000), and add the mobile phase to make 100 mL. When the procedure is run with 10 μL of this solution under the above operating conditions, aciclovir and guanine are eluted in this order with the resolution between these peaks being not less than 17.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of aciclovir is not more than 1.0%.

Containers and storage Containers—Well-closed containers.
Aciclovir Injection

Aciclovir Injection is an aqueous solution for injection.

It contains not less than 95.0% and not more than 105.0% of the labeled amount of aciclovir (C₈H₁₁N₅O₃: 225.20).

Method of preparation Prepare as directed under Injections, with Aciclovir.

Description Aciclovir Injection occurs as a colorless or pale yellow, clear liquid.

Identification To a volume of Aciclovir Injection, equivalent to 25 mg of aciclovir according to the labeled amount, add 0.5 mol/L hydrochloric acid TS to make 100 mL. To 2 mL of this solution add 0.5 mol/L hydrochloric acid TS to make 50 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry 2.24: it exhibits a maximum between 254 nm and 258 nm.

Bacterial endotoxins 4.01 Less than 0.5 EU/mg.

Extractable volume 6.05 It meets the requirement.

Foreign insoluble matter 6.06 Perform the test according to Method 1: it meets the requirement.

Insoluble particulate matter 6.07 It meets the requirement.

Sterility 4.06 Perform the test according to the Membrane filtration method: it meets the requirement.

Assay To an exact volume of Aciclovir Injection, equivalent to about 25 mg of aciclovir (C₈H₁₁N₅O₃), add 0.1 mol/L hydrochloric acid TS to make 100 mL. To 2 mL of this solution add 0.1 mol/L hydrochloric acid TS to make 50 mL, and use this solution as the sample solution. Separate, weigh accurately about 25 mg of Aciclovir RS (separately determine the water 2.40 in the same manner as Aciclovir), and dissolve in 0.1 mol/L hydrochloric acid TS to make exactly 100 mL. Pipet 2 mL of this solution, add exactly 5 mL of the internal standard solution, then add 0.1 mol/L hydrochloric acid TS to make 50 mL, and use this solution as the sample solution. Separately, weigh accurately about 25 mg of Aciclovir RS (separately determine the water 2.40 in the same manner as Aciclovir), and dissolve in 0.1 mol/L hydrochloric acid TS to make exactly 100 mL. Pipet 2 mL of this solution, add exactly 5 mL of the internal standard solution, then add 0.1 mol/L hydrochloric acid TS to make 50 mL, and use this solution as the standard solution. Perform the test with 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography 2.01 according to the following conditions, and calculate the ratios, Q₇ and Q₈, of the peak area of aciclovir to that of the internal standard.

Amount (mg) of aciclovir (C₈H₁₁N₅O₃)
= Mₛ × Q₇/Q₈

Mₛ: Amount (mg) of Aciclovir RS, calculated on the anhydrous basis

Internal standard solution—A solution of nicotinic acid in 0.1 mol/L hydrochloric acid TS (3 in 20,000).

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Aciclovir for Syrup

Aciclovir for Syrup is a preparation for syrup, which is suspended before use.

It contains not less than 95.0% and not more than 105.0% of the labeled amount of aciclovir (C₈H₁₁N₅O₃: 225.20).

Method of preparation Prepare as directed under Preparations for Syrup, with Aciclovir.

Identification Dissolve an amount of Aciclovir for Syrup, equivalent to 12 mg of Aciclovir according to the labeled amount, in 0.1 mol/L hydrochloric acid TS to make 50 mL. To 2 mL of this solution add 0.1 mol/L hydrochloric acid TS to make 50 mL, and determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry 2.24: it exhibits a maximum between 254 nm and 258 nm.

Uniformity of dosage units 6.02 Perform the test according to the following method: Aciclovir for Syrup in single-unit container meets the requirement of the Content uniformity test.

To the total content of 1 container of Aciclovir for Syrup add 27/25 mL of diluted sodium hydroxide TS (1 in 10), and treat with ultrasonic waves to disintegrate, add water to make exactly 5 mL so that each mL contains about 0.8 mg of aciclovir (C₈H₁₁N₅O₃), and filter this solution through a membrane filter with a pore size not exceeding 0.45 μm. Discard the first 2 mL of the filtrate, pipet 5 mL of the subsequent filtrate, add exactly 5 mL of the internal standard solution, then add the mobile phase to make 50 mL, and use this solution as the sample solution. Then, proceed as directed in the Assay.

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilylized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: To 1.45 g of phosphoric acid and 25 mL of dilute acetic acid add water to make 900 mL. Adjust this solution to pH 2.5 with 1 mol/L sodium hydroxide TS, and add water to make 1000 mL. To 950 mL of this solution add 50 mL of methanol.

Flow rate: Adjust the flow rate so that the retention time of aciclovir is about 7 minutes.

System suitability—
System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions, the internal standard and aciclovir are eluted in this order with the resolution between these peaks being not less than 3.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of aciclovir to that of the internal standard is not more than 1.0%.

Containers and storage Containers—Hermetic containers.
Dissolution

**Assay**

Weigh accurately an amount of Aciclovir for Syrup, equivalent to about 0.2 g of aciclovir (C₈H₁₁N₅O₃) according to the labeled amount, add 0.1 mol/L hydrochloric acid TS to make exactly 50 mL, and use this solution as the sample solution.

**Identification**

To a volume of thoroughly shaked Aciclovir Syrup, equivalent to 80 mg of Aciclovir according to the labeled amount, add 0.1 mol/L hydrochloric acid TS to make 100 mL. Centrifuge this solution, to 1 mL of the supernatant liquid add 0.1 mol/L hydrochloric acid TS to make 100 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits a maximum between 254 nm and 258 nm.

**Containers and storage**

Containers—Tight containers.

**Aciclovir Syrup**

アシクロビルシロップ

Aciclovir Syrup is a suspension syrup. It contains not less than 93.0% and not more than 107.0% of the labeled amount of aciclovir (C₈H₁₁N₅O₃: 225.20).

**Method of preparation**

Prepare as directed under Syrups, with Aciclovir.

**Operating conditions**

Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 µm in particle diameter).

Flow rate: Adjust the flow rate so that the retention time of aciclovir is about 5 minutes.

System suitability—

System performance: When the procedure is run with 20 µL of the standard solution under the above operating conditions, aciclovir and the internal standard are eluted in this order with the resolution between these peaks being not less than 20.

System repeatability: When the test is repeated 6 times with 20 µL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of aciclovir to that of the internal standard is not more than 1.0%.

**Containers and storage**

Containers—Tight containers.
<2.48> in the same manner as Aciclovir), and dissolve in water to make exactly 100 mL. Pipet 4 mL of this solution, add water to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, \( A_1 \) and \( A_5 \), at 252 nm of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry <2.26>.

Dissolution rate (%) with respect to the labeled amount of aciclovir (\( C_8H_{11}N_5O_3 \))

\[
M_S = \frac{M_T}{V_T} \times \frac{A_1}{A_5} \times 1800
\]

\( M_S \): Amount (mg) of Aciclovir RS, calculated on the anhydrous basis

\( V_T \): Amount (mL) of sample

\( C \): Labeled amount (mg) of aciclovir (\( C_8H_{11}N_5O_3 \)) in 1 mL

**Assay**  Shake thoroughly Aciclovir Syrup. To an exact volume as the standard solution. Perform the test with 20 mol/L hydrochloric acid TS to make exactly 50 mL, and use this solution as the sample solution.

Separately, weigh accurately about 40 mg of Aciclovir RS (separately determine the water <2.48> in the same manner as Aciclovir), and dissolve in 0.1 mol/L hydrochloric acid TS to make exactly 50 mL. Pipet 2 mL of this solution, add exactly 5 mL of the internal standard solution, then add 0.1 mol/L hydrochloric acid TS to make 50 mL, and use this solution as the sample solution. Separately, weigh accurately about 40 mg of Aciclovir RS and dissolve in 0.1 mol/L hydrochloric acid TS to make exactly 50 mL. Pipet 2 mL of this solution, add exactly 5 mL of the internal standard solution, then add 0.1 mol/L hydrochloric acid TS to make 50 mL, and use this solution as the standard solution. Perform the test with 20 \( \mu \)L each of the sample solution and standard solution as directed under Liquid Chromatography <2.20> according to the following conditions, and calculate the ratios, \( Q_1 \) and \( Q_5 \), of the peak area of aciclovir to that of the internal standard.

Amount (mg) of aciclovir (\( C_8H_{11}N_5O_3 \))

\[
M_S = \frac{M_T \times Q_1}{Q_5} \times 2
\]

\( M_S \): Amount (mg) of Aciclovir RS, calculated on the anhydrous basis

**Internal standard solution**—A solution of nicotinic acid in 0.1 mol/L hydrochloric acid TS (1 in 2000).

**Operating conditions**—

Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 \( \mu \)m in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: To 1.45 g of phosphoric acid and 25 mL of dilute acetic acid add water to make 900 mL. Adjust this solution to pH 2.5 with 1 mol/L sodium hydroxide TS, and add water to make 1000 mL. To 950 mL of this solution add 50 mL of methanol.

Flow rate: Adjust the flow rate so that the retention time of aciclovir is about 7 minutes.

**System suitability**—

System performance: When the procedure is run with 20 \( \mu \)L of the standard solution under the above operating conditions, the internal standard and aciclovir are eluted in this order with the resolution between these peaks being not less than 3.

System repeatability: When the test is repeated 6 times with 20 \( \mu \)L of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of aciclovir to that of the internal standard is not more than 1.0%.

**Containers and storage**  Containers—Tight containers.

### Aclarubicin Hydrochloride

Aclarubicin Hydrochloride is the hydrochloride of an anthracycline substance having antitumor activity produced by the growth of *Streptomyces galilaeus*.

It contains not less than 920 \( \mu \)g (potency) and not more than 975 \( \mu \)g (potency) per mg, calculated on the anhydrous basis. The potency of Aclarubicin Hydrochloride is expressed as mass (potency) of aclarubicin (\( C_{32}H_{37}NO_{15} \): 811.87).

**Description**  Aclarubicin Hydrochloride occurs as a yellow to pale orange-yellow powder.

It is very soluble in chloroform and in methanol, freely soluble in water, and slightly soluble in ethanol (95%).

**Identification** (1)  Determine the absorption spectrum of a solution of Aclarubicin Hydrochloride in diluted methanol (4 in 5) (3 in 100,000) as directed under Ultraviolet-visible Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2)  Determine the infrared absorption spectrum of Aclarubicin Hydrochloride as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3)  A solution of Aclarubicin Hydrochloride in methanol (1 in 200) responds to the Qualitative Tests <1.09> (2) for chloride.
Acrinol Hydrate / Official Monographs

Optical rotation $< 2.49$° [α]D$^0$: $-146 - 162°$ (50 mg calculated on the anhydrous basis, water, 10 mL, 100 mm).

pH $< 2.54$° The pH of a solution obtained by dissolving 0.05 g of Aclarubicin Hydrochloride in 10 mL of water is between 5.5 and 6.5.

Purity (1) Clarity and color of solution—Dissolve 0.10 g of Aclarubicin Hydrochloride in 10 mL of water: the solution is clear and yellow to pale orange-yellow.

(2) Heavy metals $< 1.07$°—Proceed with 1.0 g of Aclarubicin Hydrochloride according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(3) Related substances—Dissolve 10 mg of Aclarubicin Hydrochloride in 10 mL of the mobile phase, and use this solution as the sample solution. Perform the test with 20 μL of the sample solution as directed under Liquid Chromatography $< 2.01$° according to the following conditions, and determine each peak area by the automatic integration method. Calculate the amount of the related substances by the area percentage method: the amount of aclavinone having the relative retention time of about 0.6 to aclarubicin is not more than 0.2%, aclacinomycin L1 having the relative retention time of about 0.75 to aclarubicin is not more than 0.5%, 1-deoxyxypyrromycin having the relative retention time of about 1.7 to aclarubicin is not more than 1.5% and aclacinomycin S1 having the relative retention time of about 2.3 to aclarubicin is not more than 0.5%, and the total amount of the peaks other than aclarubicin and the peaks mentioned above is not more than 1.0% of the peak area of aclarubicin.

Operating conditions—
Detector: A visible absorption photometer (wavelength: 436 nm).
Column: A stainless steel column 3.9 mm in inside diameter and 30 cm in length, packed with silica gel for liquid chromatography (10 μm in particle diameter).
Column temperature: A constant temperature of about 25°C.
Mobile phase: A mixture of chloroform, methanol, acetic acid (100), and water (680:2000:1000:200:1).
Flow rate: Adjust the flow rate so that the retention time of aclarubicin is about 5 minutes.
Time span of measurement: As long as about 4 times of the retention time of aclarubicin beginning after the solvent peak.

System suitability—
Test for required detectability: Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the solution for system suitability test. Pipet 1 mL of the solution for system suitability test, and add the mobile phase to make exactly 10 mL. Confirm that the peak area of aclarubicin obtained from 20 μL of this solution is equivalent to 7 to 13% of that from 20 μL of the solution for system suitability test.

System performance: Dissolve 5 mg of Aclarubicin Hydrochloride in 10 mL of 0.1 mol/L hydrochloric acid TS, and allow to stand for 60 minutes. To 1.0 mL of this solution add 1.0 mL of 0.2 mol/L sodium hydroxide TS, 1.0 mL of phosphate buffer solution, pH 6.0 and 1.0 mL of chloroform, shake vigorously, and take the chloroform layer. When the procedure is run with 20 μL of the chloroform under the above operating conditions, aclarubicin and 1 are eluted in this order with the resolution between these peaks being not less than 3.0.

System repeatability: When the test is repeated 5 times with 20 μL of the sample solution under the above operating conditions, the relative standard deviation of the peak area of aclarubicin is not more than 2.0%.

Water $< 2.45$° Not more than 3.5% (0.1 g, volumetric titration, direct titration).

Residue on ignition $< 2.44$° Not more than 0.1% (1 g).

Assay Weigh accurately an amount of Aclarubicin Hydrochloride, equivalent to about 20 mg (potency), and dissolve in dilute methanol (4 in 5) to make exactly 100 mL. Pipet 15 mL of this solution, add dilute methanol (4 in 5) to make exactly 100 mL, and use this solution as the sample solution. Separately, weigh an accurately amount of Aclarubicin RS, equivalent to about 20 mg (potency), add 0.6 mL of diluted hydrochloric acid (1 in 250) and dilute methanol (4 in 5) to make exactly 100 mL. Pipet 15 mL of this solution, add dilute methanol (4 in 5) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry $< 2.24°$, and determine the absorbances, $A_T$ and $A_S$, at 433 nm.

Amount [μg (potency)] of aclarubicin (C42H53NO15) $= M_S \times A_T/A_S \times 1000$

$M_S$: Amount [mg (potency)] of Aclarubicin RS

Containers and storage Containers—Tight containers.
Storage—Light-resistant and at 5°C or below.

Acrinol Hydrate

Ethacridine Lactate

アクセリノール水和物

\[ \text{C}_{13}\text{H}_{15}\text{N}_3\text{O}_2\cdot\text{C}_2\text{H}_5\text{O}_2\cdot\text{H}_2\text{O}: 361.39 \]

2-Ethoxy-6,9-diaminoacridine monolactate monohydrate [1837-57-6]

Acrinol Hydrate contains not less than 98.5% and not more than 101.0% of acrinol (C15H15N3O.C3H6O3: 343.38), calculated on the anhydrous basis.

Description Acrinol Hydrate occurs as a yellow, crystalline powder. It is sparingly soluble in water, in methanol and in ethanol (99.5).

Melting point: about 245°C (with decomposition).
The pH of a solution of Acrinol Hydrate (1 in 100) is between 5.5 and 7.0.

Identification (1) Determine the absorption spectrum of a solution of Acrinol Hydrate (3 in 250,000) as directed under Ultraviolet-visible Spectrophotometry $< 2.24°$, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave-
lengths.

(2) Determine the infrared absorption spectrum of Acrinol Hydrate as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) To 5 mL of a solution of Acrinol Hydrate (1 in 100) add 5 mL of dilute sulfuric acid, shake well, allow to stand for about 10 minutes at room temperature, and filter: the filtrate responds to the Qualitative Tests <1.09> for lactate.

**Purity** (1) Chloride <1.03>—Dissolve 1.0 g of Acrinol Hydrate in 80 mL of water by warming on a water bath, cool, and add 10 mL of sodium hydroxide TS and water to make 100 mL. Shake well, allow to stand for 30 minutes, filter, to 40 mL of the filtrate add 7 mL of dilute nitric acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare 50 mL of the control solution with 4 mL of sodium hydroxide TS, 7 mL of dilute nitric acid, 0.30 mL of 0.01 mol/L hydrochloric acid VS and sufficient water (not more than 0.026%).

(2) Heavy metals <1.07>—Proceed with 1.0 g of Acrinol Hydrate according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(3) Volatile fatty acids—Dissolve 0.5 g of Acrinol Hydrate in a mixture of 20 mL of water and 5 mL of dilute sulfuric acid, shake well, filter, and heat the filtrate: no odor of volatile fatty acids is perceptible.

(4) Related substances—Dissolve 10 mg of Acrinol Hydrate in 25 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution (1). Pipet 1 mL of the standard solution (1), add the mobile phase to make exactly 10 mL, and use this solution as the standard solution (2). Perform the test with exactly 10 µL each of the sample solution and standard solutions (1) and (2) as directed under Liquid Chromatography <2.07> according to the following conditions, and determine each peak area by the automatic integration method: the area of the peak other than acrinol is not larger than 3 times the peak area of acrinol obtained with the standard solution (2), and the total area of the peaks other than acrinol is not larger than the peak area of acrinol with the standard solution (1).

**Operating conditions**—

Detector: An ultraviolet absorption photometer (wavelength: 268 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 µm in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: Dissolve 7.8 g of sodium dihydrogen phosphate in 900 mL of water, adjust to pH 2.8 with phosphoric acid, and add water to make 1000 mL. To 700 mL of this solution add 300 mL of acetonitrile for liquid chromatography, and add 1.0 g of sodium 1-octanesulfonate to dissolve. Flow rate: Adjust the flow rate so that the retention time of acrinol is about 15 minutes.

Time span of measurement: About 3 times as long as the retention time of acrinol beginning after the solvent peak.

**System suitability**—

Test for required detectability: Confirm that the peak area of acrinol obtained with 10 µL of the standard solution (2) is equivalent to 7 to 13% of that with 10 µL of the standard solution (1).

System performance: When the procedure is run with 10 µL of the standard solution (1) under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of acrinol are not less than 5000 and not more than 2.0, respectively.

System repeatability: When the test is repeated 6 times with 10 µL of the standard solution (1) under the above operating conditions, the relative standard deviation of the peak area of acrinol is not more than 1.5%.

**Water** <2.48> 4.5 – 5.5% (0.2 g, volumetric titration, direct titration)

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.27 g of Acrinol Hydrate, dissolve in 5 mL of formic acid, add 60 mL of a mixture of acetic anhydride and acetic acid (100):1:1, and titrate <2.50> immediately with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 34.34 mg of acrinol (C₁₅H₁₅N₃O₆C₃H₆O₃)

**Containers and storage** Containers—Tight containers. Storage—Light-resistant.

**Acrinol and Zinc Oxide Oil**

**Method of preparation**

Acrinol Hydrate, very finely powdered 10 g
Zinc Oxide Oil 990 g

To make 1000 g

Prepare by mixing the above ingredients.

**Description** Acrinol and Zinc Oxide Oil is a yellowish white, slimy substance. Separation of a part of its ingredients occurs on prolonged standing.

**Identification** (1) Shake well 1 g of Acrinol and Zinc Oxide Oil with 10 mL of diethyl ether, 2 mL of acetic acid (100) and 10 mL of water, and separate the water layer. Shake the layer with 5 mL of hydrochloric acid and 2 to 3 drops of sodium nitrite TS, and allow to stand: a dark red color is produced (acrinol).

(2) Place 1 g of Acrinol and Zinc Oxide Oil in a crucible, melt by warming, heat, gradually raising the temperature until the mass is thoroughly charred, and then ignite strongly: a yellow color is produced, and disappears on cooling. To the residue add 10 mL of water and 5 mL of dilute hydrochloric acid, filter after thorough shaking, and to the filtrate add 2 to 3 drops of potassium hexacyanoferrate (II) TS: a white precipitate is formed (zinc oxide).

(3) Shake well 0.2 g of Acrinol and Zinc Oxide Oil with 20 mL of ethanol (95) and 1 mL of acetic acid (100), centri-
Compound Acrinol and Zinc Oxide Oil

複方アクリノール・チンク油

Method of preparation

- Acrinol Hydrate, very finely powdered: 10 g
- Zinc Oxide Oil: 650 g
- Ethyl Aminobenzoate, finely powdered: 50 g
- White Beeswax: 20 g
- Hydrophilic Petrolatum: 270 g

To make 1000 g

Prepare by mixing the above ingredients.

Description

Compound Acrinol and Zinc Oxide Oil is light yellow to yellow in color.

Identification (1)

Shake well 1 g of Compound Acrinol and Zinc Oxide Oil with 10 mL of diethyl ether, 2 mL of acetic acid (100) and 10 mL of water, and separate the water layer. Shake the layer with 5 mL of hydrochloric acid and 2 to 3 drops of sodium nitrite TS, and allow to stand: a dark red color is produced (acrinol).

(2) Place 1 g of Compound Acrinol and Zinc Oxide Oil in a crucible, melt by warming, heat, gradually raising the temperature until the mass is thoroughly charred, and then ignite strongly: a yellow color is produced, and disappears on cooling. To the residue add 10 mL of water and 5 mL of dilute hydrochloric acid, shake well, and filter. To the filtrate add 2 to 3 drops of potassium hexacyanoferrate (II) TS: a white precipitate is produced (zinc oxide).

(3) Shake well 0.2 g of Compound Acrinol and Zinc Oxide Oil with 20 mL of ethanol (95) and 1 mL of acetic acid (100), centrifuge, filter, and use the filtrate as the sample solution. Separately, dissolve 5 mg of acrinol and 25 mg of ethylaminobenzoate in 50 mL of ethanol (95) and in 2.5 mL of acetic acid (100), respectively, and use both solutions as the standard solutions (1) and (2). Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 5 μL of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of diethyl ether, ethanol (95) and acetic acid (100) (40:10:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): the spots from the sample solution and standard solution exhibit a blue fluorescence and show the same Rf value.

Containers and storage

Containers—Tight containers.

Storage—Light-resistant.

Acrinol and Zinc Oxide Ointment

アクリノール・亜鉛華軟膏

Method of preparation

- Acrinol Hydrate, very finely powdered: 10 g
- Zinc Oxide Ointment: 990 g

To make 1000 g

Prepare as directed under Ointments, with the above ingredients.

Description

Acrinol and zinc oxide ointment is yellow in color.

Identification (1)

Shake 0.5 g of Acrinol and Zinc Oxide Ointment with 5 mL of diethyl ether, 5 mL of dilute hydrochloric acid and 2 to 3 drops of sodium nitrite TS, and allow to stand: a dark red color develops in the water layer (acrinol).

(2) Ignite 0.5 g of Acrinol and Zinc Oxide Ointment to char, and dissolve the residue in 5 mL of dilute hydrochloric acid: the solution responds to the Qualitative Tests <1.09> for zinc salt.

(3) Shake 0.5 g of Acrinol and Zinc Oxide Ointment with 5 mL of diethyl ether, 1 mL of acetic acid (100) and 5 mL of water, separate the water layer, and use the water layer as the sample solution. Dissolve 5 mg of acrinol in 1 mL of acetic acid (100) and 5 mL of water, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 5 μL of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of diethyl ether, ethanol (95) and acetic acid (100) (40:10:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 365 nm): the spots from the sample solution and the standard solution exhibit a blue fluorescence and show the same Rf value.

Containers and storage

Containers—Tight containers.

Storage—Light-resistant.
Actinomycin D

アクチノマイシン D

Actinomycin D is a peptide substance having anti-tumor activity produced by the growth of Streptomyces parvulus.

It, when dried, contains not less than 950 μg (potency) and not more than 1030 μg (potency) per mg. The potency of Actinomycin D is expressed as mass (potency) of actinomycin D (C_{62}H_{86}N_{12}O_{16}).

**Description**

Actinomycin D occurs as an orange-red to red crystalline powder.

It is freely soluble in acetone, sparingly soluble in acetonitrile and in methanol, slightly soluble in ethanol (99.5), and very slightly soluble in water.

**Identification (1)**

Determine the absorption spectrum of a solution of Actinomycin D in methanol (3 in 100,000) as directed under Ultraviolet-visible Spectrophotometry <2,24>, and compare the spectrum with the Reference Spectrum or the spectrum of a solution of Actinomycin D RS prepared in the same manner as the sample solution: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Dissolve 0.1 g each of Actinomycin D and Actinomycin D RS in 10 mL of acetone, and use these solutions as the sample solution and standard solution. Perform the test with exactly 25 μL of the standard solution under the above operating conditions, and determine the peak area of actinomycin D, A_t, and A_s, of both solutions.

System suitability—

System performance: When the procedure is run with 25 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of actinomycin D are not less than 2000 steps and not more than 1.5, respectively.

System repeatability: When the test is repeated 5 times with 25 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of actinomycin D is not more than 2.0%.

**Containers and storage**

Containers—Tight containers.

Storage—Light-resistant.

Adrenaline

アドレナリン

Adrenaline occurs as a white to grayish white, crystalline powder.

It is freely soluble in formic acid and in acetic acid (100), very slightly soluble in water, and practically insoluble in methanol and in ethanol (99.5).

It dissolves in dilute hydrochloric acid.

It gradually changes to brown in color by air and by light.

**Identification (1)**

Determine the absorption spectrum of a solution of Adrenaline in 0.01 mol/L hydrochloric acid TS (1 in 25,000) as directed under Ultraviolet-visible Spectrophotometry <2,24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of
Adrenaline as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

Optical rotation <2.49> $[\alpha]_D^{25} - 50.0 - 53.5 ^\circ$ (after drying, 1 g, 1 mol/L hydrochloric acid TS, 25 mL, 100 mm).

Purity (1) Clarity and color of solution—Dissolve 0.10 g of Adrenaline in 10 mL of dilute hydrochloric acid: the solution is clear, and is not more colored than Matching Fluid A.

(2) Heavy metals <1.07>—Proceed with 1.0 g of Adrenaline according to Method 4, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(3) Adrenalone—Dissolve 50 mg of Adrenaline in 0.05 mol/L hydrochloric acid TS to make exactly 25 mL, and determine the absorbance of this solution at 310 nm as directed under Ultraviolet-visible Spectrophotometry <2.24>: it is not more than 0.2.

(4) Noradrenaline—Dissolve 0.20 g of Adrenaline in 1 mL of formic acid, add methanol to make exactly 10 mL, and use this solution as the sample solution. Separately, dissolve 8.0 mg of Noradrenaline Bitartrate RS in methanol to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.05>. Spot 5 µL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of 1-butanol, water and formic acid (7:2:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly Folin’s TS on the plate: the spot obtained from the sample solution, corresponding to the spot from the standard solution, is not more intense than the spot from the standard solution.

Loss on drying <2.41> Not more than 1.0% (1 g, in vacuum, silica gel, 18 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Weigh accurately about 0.3 g of Adrenaline, previously dried, dissolve in 50 mL of acetic acid (100), and titrate <2.50> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS $= 18.32$ mg of $C_9H_{13}NO_3$.

Containers and storage—Tight containers.

Storage—Light-resistant, and under Nitrogen atmosphere.

Method of preparation—Dissolve Adrenaline in diluted Hydrochloric Acid (9 in 10,000), and prepare as directed under Injections.

Identification (1) To 1 mL of Adrenaline Injection add 4 mL of water and 1 drop of iron (III) chloride TS: a deep green color is produced, and it gradually changes to red.

(2) Place 1 mL each of Adrenaline Injection in test tubes A and B, and proceed as directed in the Identification (2) under Adrenaline.

Extractable volume <6.05> It meets the requirement.

Assay Pipet 30 mL of Adrenaline Injection into a separator, add 25 mL of carbon tetrachloride, shake vigorously for 1 minute, allow the liquids to separate, and discard the carbon tetrachloride. Repeat this procedure three times. Rinse the stopper and mouth of the separator with a small amount of water. Add 0.2 mL of starch TS, then while swirling the separator add iodine TS dropwise until a persistent blue color develops, and immediately add sodium thiosulfate TS to discharge the blue color. Add 2.1 g of sodium hydrogen carbonate to the liquid in the separator, preventing it from coming in contact with the mouth of the separator, and shake until most of the sodium hydrogen carbonate dissolves. Rapidly inject 1.0 mL of acetic anhydride into the contents of the separator. Immediately stopper the separator loosely, and allow to stand until the evolution of gas ceases. Shake vigorously, allow to stand for 5 minutes, extract with six 25-mL portions of chloroform, and filter each chloroform extract through a pledget of absorbent cotton. Evaporate the combined chloroform extracts on a water bath in a current of air to 3 mL, completely transfer this residue by means of small portions of chloroform to a tared beaker, and heat again to evaporate to dryness. Dry the residue at 105°C for 30 minutes, cool in a desiccator (silica gel), and accurately measure the mass $M$ (mg) of the dried residue. Dissolve in chloroform to make exactly 5 mL, and determine the optical rotation <2.49> $[\alpha]_D^{20}$ using a 100-mm cell.

Amount (mg) of adrenaline ($C_9H_{13}NO_3$) $= M \times (0.5 + (0.5 \times [\alpha]_D^{20} / 93)) \times 0.592$

Containers and storage—Containers—Hermetic containers, and colored containers may be used.

Storage—Light-resistant.

Adrenaline Injection

Epinephrine Injection

Adrenaline Injection is aqueous solution for injection.

It contains not less than 0.085 w/v% and not more than 0.115 w/v% of adrenaline ($C_9H_{13}NO_3$: 183.20).

Adrenaline Solution

Epinephrine Solution

Adrenaline Solution contains not less than 0.085 w/v% and not more than 0.115 w/v% of adrenaline ($C_9H_{13}NO_3$: 183.20).

Afloqualone

アフロクアロン

![Afloqualone molecule](image)

C₁₆H₁₄FN₃O: 283.30
6-Amino-2-fluoromethyl-3-(2-tolyl)-3H-quinazolin-4-one [56287-74-2]

Afloqualone, when dried, contains not less than 98.5% of C₁₆H₁₄FN₃O.

Description Afloqualone occurs as white to light yellow crystals or crystalline powder.
It is soluble in acetonitrile, sparingly soluble in ethanol (99.5), and practically insoluble in water.
It is gradually colored by light.
Melting point: about 197°C (with decomposition).

Identification (1) Conduct this procedure without exposure to light, using light-resistant containers. Determine the absorption spectrum of a solution of Afloqualone in ethanol (99.5) (1 in 150,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Afloqualone, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

Purity (1) Acidity or alkalinity—Take 1.0 g of Afloqualone in a light-resistant vessel, add 20 mL of freshly boiled and cooled water, shake well, and filter. To 10 mL of the filtrate add 2 drops of bromothymol blue TS: a yellow color develops. The color changes to blue by adding 0.20 mL of 0.01 mol/L sodium hydroxide TS.

(2) Heavy metals: <1.07>—Proceed with 2.0 g of Afloqualone in a platinum crucible according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(3) Related substances—Conduct this procedure without exposure to light, using light-resistant vessels. Dissolve 10 mg of Afloqualone in 25 mL of the mobile phase, and use this solution as the sample solution. Pipet 3 mL of the sample solution, add the mobile phase to make exactly 100 mL. Pipet 2 mL of this solution, add the mobile phase to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and calculate the areas of each peak by the automatic integration method: the total of the peak areas other than the peak area of afloqualone from the sample solution is not larger than the peak area of afloqualone from the standard solution.

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 254 nm).
Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Mobile phase: Dissolve 7.2 g of disodium hydrogen phosphate dodecahydrate in 1000 mL of water, adjust to pH 5.5 with diluted phosphoric acid (1 in 10). To 600 mL of this solution add 400 mL of acetonitrile.
Flow rate: Adjust the flow rate so that the retention time of afloqualone is about 5.5 minutes.
Time span of measurement: About 4 times as long as the retention time of afloqualone beginning after the solvent peak.
System suitability—
Test for required detection: Pipet 5 mL of the standard solution, add the mobile phase to make exactly 25 mL, and confirm that the peak area of afloqualone obtained from 20 μL of this solution is equivalent to 15 to 25% of that of afloqualone obtained from 20 μL of the standard solution.
System performance: Dissolve 0.01 g of Afloqualone in a suitable amount of the mobile phase, add 5 mL of a solution of propyl parahydroxybenzoate in the mobile phase (1 in 2000) and the mobile phase to make 100 mL. When the procedure is run with 20 μL of this solution under the above operating conditions, afloqualone and propyl parahydroxybenzoate are eluted in this order with the resolution between these peaks being not less than 4.
System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak areas of afloqualone is not more than 5%.

Loss on drying <2.41> Not more than 0.5% (1 g, in vacu-
 Ajmaline Tablets

Ajmaline Tablets contain not less than 90.0% and not more than 110.0% of the labeled amount of ajmaline (C20H26N2O2: 326.43).

**Method of preparation** Prepare as directed under Tablets, with Ajmaline.

**Identification (1)** Shake a quantity of powdered Ajmaline Tablets, equivalent to 0.1 g of Ajmaline according to the labeled amount, with 30 mL of chloroform, and filter. Evaporate the filtrate on a water bath to dryness. With the residue, proceed as directed in the Identification under Ajmaline.

(2) Dissolve 0.01 g of the residue of (1) in 100 mL of methanol, and use this solution as the sample solution. Add 3 mL of nitric acid to 1 mL of the sample solution: a deep red color develops.

**Optical rotation** \( \left[ \alpha \right] _{D}^{20} +136^\circ - +151^\circ \) (after drying, 0.5 g, chloroform, 50 mL, 100 mm).

**Uniformity of dosage units** Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Ajmaline Tablets add 150 mL of 2nd fluid for dissolution test, shake to disintegrate the tablet, then add 2nd fluid for dissolution test to make exactly 200 mL, and filter this solution through a membrane filter with a pore size not exceeding 0.8 \( \mu \)m. Discard the first 10 mL of the filtrate, pipet \( V \) mL of the subsequent filtrate equivalent to about 0.5 mg of ajmaline (C20H26N2O2), add 2nd fluid for dissolution test to make exactly 10 mL, and use this solution as the sample solution. Separately, weigh accurately about 25 mg of
ajimaline for assay, previously dried in vacuum at 80°C for 3 hours, dissolve in 2nd fluid for dissolution test to make exactly 500 mL, and use this solution as the standard solution. Determine the absorbances at 288 nm, $A_T$ and $A_S$, of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry. 

$$M_a = M_b \times A_T/A_S \times V/V \times 1/C \times 180$$

$M_a$: Amount (mg) of ajimaline for assay.

**Assay**

Weigh accurately and powder not less than 20 Ajimaline Tablets. Weigh accurately a portion of the powder, equivalent to about 0.3 g of ajimaline (C$_{20}$H$_{26}$N$_2$O$_2$), add 15 Ajimaline Tablets. Weigh accurately a portion of the powder, and use this solution as the sample solution. 

**Dissolution**

When the test is performed at 100 revolutions per minute according to the Paddle method, using 900 mL of 2nd fluid for dissolution test as the dissolution medium, the dissolution rate in 60 minutes of Ajimaline Tablets is not less than 75%.

Start the test with 1 tablet of Ajimaline Tablets, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.8 μm. Discard the first 10 mL of the filtrate, pipet $V$ mL of the subsequent filtrate, add the dissolution medium to make exactly $V' \text{ mL}$ so that each mL contains about 56 μg of ajimaline (C$_{20}$H$_{26}$N$_2$O$_2$) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 28 mg of ajimaline for assay, previously dried in vacuum at 80°C for 3 hours, dissolve in the dissolution medium to make exactly 500 mL, and use this solution as the standard solution. Determine the absorbances, $A_T$ and $A_S$, of the sample solution and standard solution at 288 nm as directed under Ultraviolet-visible Spectrophotometry. 

**Optical rotation**

$\alpha_{D}^{20} = -81°\text{ to } -85°$ (after drying, 0.25 g, ethanol (95), 25 mL, 100 mm).

**Melting point**

153° to 157°C

**Purity**

(1) Chloride $<1.03$—Dissolve 0.5 g of Alacepril in 30 mL of methanol, add 6 mL of dilute nitric acid and water to make 50 mL, and perform the test with this solution as the test solution. Prepare the control solution as follows: to 0.30 mL of 0.01 mol/L hydrochloric acid VS add 30 mL of methanol, 6 mL of dilute nitric acid and water to make 50 mL (not more than 0.021%).

(2) Sulfate $<1.14$—Dissolve 0.5 g of Alacepril in 30 mL of methanol, add 1 mL of dilute hydrochloric acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution as follows: to 0.50 mL of 0.005 mol/L sulfuric acid VS add 30 mL of methanol, 1 mL of dilute hydrochloric acid and water to make 50 mL (not more than 0.048%).

(3) Heavy metals $<1.07$—Proceed with 1.0 g of Alacepril according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(4) Related substances—Dissolve 50 mg of Alacepril in 5 mL of ethanol (95), and use this solution as the sample solution. Pipet 1 mL of the sample solution, add ethanol (95) to
make exactly 200 mL and use this solution as the standard solution. Perform the test with exactly 10 \( \mu L \) of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine each peak area by the automatic integration method: the area of the peak other than alacepril from the sample solution is not larger than 1/5 times the peak area of alacepril from the standard solution, and the total area of the peaks other than the peak of alacepril from the sample solution is not larger than the peak area of alacepril from the standard solution. For this calculation, use the areas of the peaks, having the relative retention time of about 2.3 and about 2.6 with respect to alacepril, after multiplying by their sensitivity factors, 1.5 and 1.9, respectively.

**Operating conditions**

Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylosilanized silica gel for liquid chromatography (5 \( \mu m \) in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of diluted acetic acid (100) (1 in 100), acetonitrile, methanol and tetrahydrofuran (6:2:1:1).

Flow rate: Adjust the flow rate so that the retention time of alacepril is about 5 minutes.

Time span of measurement: About 3 times as long as the retention time of alacepril beginning after the solvent peak.

**System suitability**

Test for required detectability: To exactly 4 mL of the standard solution add ethanol (95) to make exactly 10 mL. Confirm that the peak area of alacepril obtained with 10 \( \mu L \) of this solution is equivalent to 30 to 50% of that with 10 \( \mu L \) of the standard solution.

System performance: Dissolve 20 mg of Alacepril in 50 mL of a solution of propyl parahydroxybenzoate in ethanol (95) (1 in 80,000). When the procedure is run with 10 \( \mu L \) of this solution under the above operating conditions, alacepril and propyl parahydroxybenzoate are eluted in this order with the resolution between these peaks being not less than 7.

System repeatability: When the test is repeated 6 times with 10 \( \mu L \) of the standard solution under the above operating conditions, the relative standard deviation of the peak area of alacepril is not more than 2.0%.

**Loss on drying** <2.41> Not more than 1.0% (1 g, 105°C, 3 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.6 g of Alacepril, previously dried, dissolve in 75 mL of a mixture of methanol and water (2:1), and titrate <2.50> with 0.1 mol/L sodium hydroxide VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L sodium hydroxide VS = 40.65 mg of C\(_{20}H_{26}N_2O_5S\)

**Containers and storage** Containers—Tight containers.

---

### Alacepril Tablets

Alacepril Tablets contain not less than 95.0% and not more than 105.0% of the labeled amount of alacepril (C\(_{20}H_{26}N_2O_5S\): 406.50).

**Method of preparation** Prepare as directed under Tablets, with Alacepril.

**Identification** Shake well a quantity of powdered Alacepril Tablets, equivalent to 0.1 g of Alacepril according to the labeled amount, with 10 mL of ethanol (95), filter, and use the filtrate as the sample solution. Separately, dissolve 10 mg of alacepril in 1 mL of ethanol (95), and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.02>. Spot 5 \( \mu L \) each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography, develop the plate with a mixture of ethanol (99.5) and hexane (2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the principal spot from the sample solution and the spot from the standard solution show the same color tone and \( R_f \) value.

**Uniformity of dosage units** <6.02> Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Alacepril Tablets add 2 mL of water, disperse the particle with the aid of ultrasonic wave, and add exactly 2 mL of the internal standard solution every 10 mg of alacepril (C\(_{20}H_{26}N_2O_5S\)) according to the labeled amount. To this solution add a suitable amount of methanol, extract for 15 minutes with the aid of ultrasonic wave while occasional shaking, and shake more 15 minutes. Add methanol to make \( V \) mL so that each mL of the solution contains about 0.5 mg of alacepril (C\(_{20}H_{26}N_2O_5S\)), centrifuge, and use the supernatant liquid as the sample solution. Separately, weigh accurately about 25 mg of alacepril for assay, previously dried at 105°C for 3 hours, add exactly 5 mL of the internal standard solution and methanol to make 50 mL, and use this solution as the standard solution. Perform the test with 10 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and calculate the ratios, \( Q_1 \) and \( Q_2 \), of the peak area of alacepril to that of the internal standard.

Amount (mg) of alacepril (C\(_{20}H_{26}N_2O_5S\)) = \( M_5 \times Q_1 / Q_2 \times V / 50 \)

\( M_5 \): Amount (mg) of alacepril for assay

**Internal standard solution**—A solution of propyl parahydroxybenzoate in methanol (3 in 20,000).

**Operating conditions**

Proceed as directed in the operating conditions in the Assay.

**System suitability**

Proceed as directed in the system suitability in the Assay.

**Dissolution** <6.10> When the test is performed at 50 revolutions per minute according to the Paddle method, using 900 mL of water as the dissolution medium, the dissolution rate...
of a 12.5-mg tablet and a 25-mg tablet in 30 minutes is not less than 75%, and that of a 50-mg tablet in 30 minutes is not less than 70%.

Start the test with 1 tablet of Alacepril Tablets, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.45 μm. Discard the first 10 mL of the filtrate, pipet V mL of the subsequent filtrate, add water to make exactly V mL so that each mL contains about 14 μg of alacepril (C₂₀H₂₆N₂O₅S) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 14 mg of alacepril for assay, previously dried at 105°C for 3 hours, dissolve in 2 mL of methanol, and add water to make exactly 100 mL. Pipet 5 mL of this solution, add water to make exactly 50 mL, and use this solution as the standard solution. Determine the absorbances at A₁₁, A₁₂, A₁₃, and A₁₄ at 300 nm, of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry <2.2₄₅>, using water as the blank.

Dissolution rate (%) with respect to the labeled amount of alacepril (C₂₀H₂₆N₂O₅S) = M₅ × (A₁₁ - A₁₃)/(A₁₁ - A₁₃) × V/V × 1/C × 90

M₅: Amount (mg) of alacepril for assay
C: Labeled amount (mg) of alacepril (C₂₀H₂₆N₂O₅S) in 1 tablet

Assay Weigh accurately, and powder not less than 20 Alacepril Tablets. Weigh accurately a portion of the powder, equivalent to about 50 mg of alacepril (C₂₀H₂₆N₂O₅S), moisten with 2 mL of water, add exactly 3 mL of the internal standard solution and 40 mL of methanol, extract for 15 minutes with the aid of ultrasonic wave, cool, and add methanol to make 50 mL. Centrifuge this solution, and use the supernatant liquid as the sample solution. Separately, weigh accurately about 50 mg of alacepril for assay, previously dried at 105°C for 3 hours, dissolve in 2 mL of methanol, and add water to make exactly 100 mL. Pipet 5 mL of this solution, add water to make exactly 50 mL, and use this solution as the standard solution. Determine the absorbances, A₁₁ and A₁₃, at 230 nm, and A₁₂ and A₁₄, at 300 nm, of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry <2.2₄₅>, using water as the blank.

System suitability—

dissolution rate (%) with respect to the labeled amount of alacepril (C₂₀H₂₆N₂O₅S) = M₅ × (A₁₁ - A₁₃)/(A₁₁ - A₁₃) × V/V × 1/C × 90

M₅: Amount (mg) of alacepril for assay
C: Labeled amount (mg) of alacepril (C₂₀H₂₆N₂O₅S) in 1 tablet

Containers and storage—

L-Alanine, when dried, contains not less than 98.5% and not more than 101.0% of C₃H₇NO₂.

Description L-Alanine occurs as white crystals or crystalline powder. It has a slightly sweet taste. It is freely soluble in water and in formic acid, and practically insoluble in ethanol (99.5). It dissolves in 6 mol/L hydrochloric acid TS.

Identification—

Determine the infrared absorption spectrum of L-Alanine as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.2₅₉>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

Optical rotation <2.₄₉₉> [α]₀°: +13.5 – +15.5° (after drying, 2.5 g, 6 mol/L hydrochloric acid TS, 25 mL, 100 mm).

pH <2.₅₄₉>—Dissolve 1.0 g of L-Alanine in 20 mL of water: the pH of the solution is between 5.7 and 6.7.

Purity (1) Clarity and color of solution—Dissolve 1.0 g of L-Alanine in 10 mL of water: the solution is clear and colorless.

(2) Chloride <1.₀₇₉>—Perform the test with 0.5 g of L-Alanine. Prepare the control solution with 0.30 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.021%)

(3) Sulfate <1.₁₄₉>—Perform the test with 0.6 g of L-Alanine. Prepare the control solution with 0.35 mL of 0.005 mol/L sulfuric acid VS (not more than 0.028%)

(4) Ammonium <1.₀₂₉>—Perform the test with 0.25 g of L-Alanine. Prepare the control solution with 5.0 mL of Standard Ammonium Solution (not more than 0.02%).

(5) Heavy metals <1.₀₇₉>—Proceed with 1.0 g of L-Alanine according to Method 1, and perform the test. Prepare the control solution with 1.0 mL of Standard Lead Solution (not more than 10 ppm).

(6) Iron <1.₁₇₉>—Prepare the test solution with 1.0 g of L-Alanine according to Method 1, and perform the test according to Method A. Prepare the control solution with
1.0 mL of Standard Iron Solution (not more than 10 ppm).

(7) Related substances—Weigh accurately about 0.5 g of L-Alanine, dissolve in 0.5 mL of hydrochloric acid and water to make exactly 100 mL. Pipet 10 mL of this solution, add 0.02 mol/L hydrochloric acid TS to make exactly 50 mL, and use this solution as the sample solution. Separately, accurately measure 2.5 mmol amounts of L-aspartic acid, L-threonine, L-serine, L-glutamic acid, glycine, L-alanine, L-cystine, L-valine, L-methionine, L-isoleucine, L-leucine, L-tyrosine, L-phenylalanine, L-lysine hydrochloride, ammonium chloride, L-histidine and L-arginine, dissolve in 0.1 mol/L hydrochloric acid TS to make exactly 1000 mL, and use this solution as the standard stock solution. Pipet 5 mL of the standard stock solution, add 0.02 mol/L hydrochloric acid TS to make exactly 100 mL. Pipet 4 mL of this solution, add 0.02 mol/L hydrochloric acid TS to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions. Based on the peak heights obtained from the sample solution and standard solution, determine the mass of the amino acids other than alanine contained in 1 mL of the sample solution, and calculate the mass percent: the amount of each amino acid other than alanine is not more than 0.1%.

Operating conditions—
Detector: A visible spectrophotometer (wavelength: 570 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 8 cm in length, packed with strongly acidic ion-exchange resin for liquid chromatography (Na type) composed with a sulfonated polystyrene copolymer (3 μm in particle diameter).

Column temperature: A constant temperature of about 57°C. Chemical reaction bath temperature: A constant temperature of about 130°C.

Reaction time: About 1 minute.
Mobile phase: Prepare mobile phases A, B, C, D and E according to the following table, and add 0.1 mL of capric acid to each mobile phase.

Total volume 1000 mL 1000 mL 1000 mL 1000 mL 1000 mL

Changing mobile phases: When the procedure is run with 20 μL of the standard solution under the above operating conditions, switchover in sequence to mobile phases A, B, C, D and E so that aspartic acid, threonine, serine, glutamic acid, glycine, alanine, cystine, valine, methionine, isoleucine, leucine, tyrosine, phenylalanine, lysine, ammonia, histidine, and arginine are eluted in this order with the resolution between the peaks of isoleucine and leucine being not less than 1.2.

Reaction reagents: Dissolve 204 g of lithium acetate dihydrate in water, add 123 mL of acetic acid (100) and 401 mL of 1-methoxy-2-propanol, and water to make 1000 mL, introduce nitrogen for 10 minutes, and use this solution as solution (I). Separately, add 39 g of ninhydrin to 979 mL of 1-methoxy-2-propanol, introduce nitrogen for 5 minutes, add 81 mg of sodium borohydride, introduce nitrogen for 30 minutes, and use this solution as solution (II). To 1 volume of solution (I) add 1 volume of solution (II). Prepare before use.

Flow rate of mobile phase: 0.20 mL per minute.
Flow rate of reaction reagent: 0.24 mL per minute.

System suitability—
System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions, the resolution between the peaks of glycine and alanine is not less than 1.2.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviations of the peak height and retention time of each amino acid obtained from the standard solution are not more than 5.0% and not more than 1.0%, respectively.

Loss on ignition <2.44> Not more than 0.3% (1 g, 105°C, 3 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Weigh accurately about 90 mg of L-Alanine, previously dried, dissolve in 3 mL of formic acid, add 50 mL of acetic acid (100), and titrate <2.50> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 8.909 mg of C,H$_2$NO$_2$

Containers and storage Containers—Tight containers.

**Albumin Tannate**

タンニン酸アルブミン

Albumin Tannate is a compound of tannic acid and a protein. The label states the origin of the protein of Albumin Tannate.

**Description** Albumin Tannate occurs as a light brown powder. It is odorless, or has a faint, characteristic odor. It is practically insoluble in water and in ethanol (95). It dissolves in sodium hydroxide TS with turbidity.

**Identification** (1) To 0.1 g of Albumin Tannate add 10 mL of ethanol (95), and heat in a water bath for 3 minutes with shaking. After cooling, filter, and to 5 mL of the fil-
trate add 1 drop of iron (III) chloride TS: a blue-purple to bluish black color is produced. On standing, a bluish black precipitate is produced.

(2) To 0.1 g of Albumin Tannate add 5 mL of nitric acid: an orange-yellow color develops.

**Purity (1)** Acidity—Shake 1.0 g of Albumin Tannate with 50 mL of water for 5 minutes, and filter. To 25 mL of the filtrate add 1.0 mL of 0.1 mol/L sodium hydroxide VS 2 drops of phenolphthalein TS: a red color develops.

(2) Fats—To 2.0 g of Albumin Tannate add 20 mL of petroleum benzine, shake vigorously for 15 minutes, and filter. Evaporate 10 mL of the filtrate on a water bath: the mass of the residue is not more than 50 mg.

**Residue on ignition**<sup>2.44</sup> Not more than 1.0% (0.5 g).

**Digestion test** To 1.00 g of Albumin Tannate add 0.25 g of saccharated pepsin and 100 mL of water, shake well, and allow to stand for 20 minutes at 40±1°C in a water bath. Add 1.0 mL of dilute hydrochloric acid, shake, and allow to stand for 3 hours at 40±1°C. Cool rapidly to ordinary temperature, and filter. Wash the residue with 3-10 mL portions of water, dry in a desiccator (silica gel) for 18 hours, and dry at 105°C for 3 hours: the mass of the residue is 0.50 to 0.58 g.

**Containers and storage** Containers—Tight containers. Storage—Light-resistant.

**Aldioxa**

アルジオキサ

![Chemical Structure](image)

C₃H₁₉AlN₅O₇: 218.10
Dihydroxo(5-oxo-4-ureido-4,5-dihydro-1H-imidazol-2-yl)oxyaluminium [5579-81-7]

Aldioxa is a condensation product of allantoin and aluminum hydroxide. When dried, it contains not less than 65.3% and not more than 74.3% of allantoin (C₆H₃N₃O₇: 158.12), and not less than 11.1% and not more than 13.0% of aluminum (Al: 26.98).

**Description** Aldioxa occurs as a white powder. It is odorless and tasteless.

It is practically insoluble in water, in ethanol (95) and in diethyl ether.

It dissolves in dilute hydrochloric acid and in dilute nitric acid.

Melting point: about 230°C (with decomposition).

**Identification (1)** To 0.2 g of Aldioxa add 10 mL of dilute hydrochloric acid, boil for 5 minutes, and add 10 mL of a solution of phenylhydrazinium chloride (1 in 100). After cooling, mix well with 0.5 mL of potassium hexacyanoferrate (III) TS, and shake with 1 mL of hydrochloric acid: a red color develops.

(2) To 0.2 g of Aldioxa add 10 mL of dilute hydrochloric acid, dissolve by warming, and cool: the solution responds to the Qualitative Tests.<sup>1.09</sup> for aluminum salt.

**Purity (1)** Chloride <1.03>—To 0.10 g of Aldioxa add 6 mL of dilute nitric acid, boil with shaking for 5 minutes, cool, and add water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 0.40 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.142%).

(2) Sulfate <1.14>—To 0.20 g of Aldioxa add 6 mL of dilute hydrochloric acid, boil with shaking for 5 minutes, cool, and add water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 1.0 mL of 0.005 mol/L sulfuric acid VS (not more than 0.240%).

(3) Nitrate—To 0.10 g of Aldioxa add carefully 5 mL of water and 5 mL of sulfuric acid, dissolve by shaking, cool, and superimpose 2 mL of iron (II) sulfate TS: no brown ring is produced at the zone of contact.

(4) Heavy metals <1.07>—To 1.0 g of Aldioxa add 3 mL of hydrochloric acid and 3 mL of water, heat gently to boil with shaking, and evaporate on a water bath to dryness. To the residue add 30 mL of water, shake under warming, cool, filter, and to the filtrate add 2 mL of dilute acetic acid (31) and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: to 3 mL of hydrochloric acid add 3 mL of water, evaporate on a water bath to dryness, and add 2.0 mL of Standard Lead Solution, 2 mL of dilute acetic acid (31) and water to make 50 mL (not more than 20 ppm).

(5) Arsenic <1.11>—Prepare the test solution with 1.0 g of Aldioxa according to Method 2, and perform the test (not more than 2 ppm).

**Loss on drying**<sup>2.44</sup> Not more than 4.0% (1 g, 105°C, 2 hours).

**Assay (1)** Allantoin—Weigh accurately about 0.1 g of Aldioxa, previously dried, dissolve in 50 mL of dilute sulfuric acid by heating, cool, and add water to make exactly 100 mL. Pipet 10 mL of this solution, and perform the test as directed under Nitrogen Determination<sup>1.08</sup>. Each mL of 0.005 mol/L sulfuric acid VS = 0.3953 mg of C₃H₉N₅O₇

(2) Aluminum—Weigh accurately about 0.2 g of Aldioxa, previously dried, dissolve carefully in 50 mL of dilute hydrochloric acid by heating, cool, and add dilute hydrochloric acid to make exactly 100 mL. Pipet 4 mL of this solution, add water to make exactly 25 mL, and use this solution as the sample solution. Separately, pipet a suitable quantity of Standard Aluminum Solution, dilute with water so that each mL of the solution contains not less than 16.0 μg and not more than 64.0 μg of aluminum (Al: 26.98), and use this solution as the standard solution. Perform the test with the sample solution and standard solution as directed under Atomic Absorption Spectrophotometry<sup>2.23</sup> according to the following conditions, and calculate the aluminum content of the sample solution from the calibration curve obtained from the absorbance of the standard solu-
Alendronate Sodium Hydrate

アルレンドロン酸ナトリウム水和物

\[
\text{C}_4\text{H}_{12}\text{NNaO}_7\text{P}_2\cdot3\text{H}_2\text{O}: 325.12
\]

Monosodium trihydrogen 4-amino-1-hydroxybutane-1,1-diylidiphosphonate trihydrate

\[\text{H}_2\text{N} \quad \text{PO}_3\text{HNa} \quad \text{PO}_3\text{H}_2 \quad \cdot 3\text{H}_2\text{O}\]

Alendronate Sodium Hydrate contains not less than 99.0% and not more than 101.0% of alendronate sodium (\(\text{C}_4\text{H}_{12}\text{NNaO}_7\text{P}_2: 271.08\)), calculated on the dried basis.

**Description**

Alendronate Sodium Hydrate occurs as a white crystalline powder.

It is sparingly soluble in water, and practically insoluble in ethanol (99.5).

It dissolves in 0.1 mol/L trisodium citrate TS.

Melting point: about 252°C (with decomposition, after drying).

**Identification** (1)

To 5 mL of a solution of Alendronate Sodium Hydrate (1 in 50) add 1 mL of ninhydrin TS, and heat: a blue-purple color develops.

(2) Determine the infrared absorption spectrum of Alendronate Sodium Hydrate as directed in the potassium bromide disk method under Infrared Spectrophotometry (2.25), and compare the spectrum with the Reference Spectrum or the spectrum of Alendronate Sodium RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) To 0.1 g of Alendronate Sodium Hydrate add 10 mL of a mixture of nitric acid and perchloric acid (1:1). Heat to concentrate to about 1 mL, add about 10 mL of water while hot, and neutralize with a solution of sodium hydroxide (2 in 5): the solution responds to the Qualitative Tests <1.09> for phosphate.

(4) A solution of Alendronate Sodium Hydrate (1 in 100) responds to the Qualitative Tests <1.09> for sodium salt.

**pH** <2.54>

The pH of a solution of 1.0 g of Alendronate Sodium Hydrate in 100 mL of freshly boiled and cooled water is between 4.0 and 5.0.

**Purity** (1) Heavy metals <1.07>—Put 1.0 g of Alendronate Sodium Hydrate in a Kjeldahl flask, add 9 mL of a mixture of nitric acid and sulfuric acid (5:4), and heat until the solution becomes brown. After cooling, add 9 mL of a mixture of nitric acid and sulfuric acid (5:4), and heat again until the color changes from colorless to brown. After cooling, add 2 mL of nitric acid, strongly heat until brown fumes are no longer evolved, and heat until large amounts of white fumes are evolved. After cooling, add carefully 5 mL of water and 1 mL of hydrogen peroxide (30), heat until white fumes are no longer evolved, and continue heating for more 5 minutes. After cooling, if any yellow color remains, add 2 mL of nitric acid, and repeat the same procedure. After cooling, transfer the solution in the Kjeldahl flask to a beaker, wash out the inside of the flask with 5 mL of water, and add the washing to the beaker. Adjust to pH 3 – 5 with ammonia solution (28), transfer to a Nessler tube, add water to make 50 mL, and perform the test with this solution as the test solution. Prepare the control solution in the same procedure using the same amount of the reagents used for the preparation of the sample solution, add 1.0 mL of Standard Lead Solution and add water to make 50 mL (not more than 10 ppm).

(2) Related substances—Dissolve 15 mg of Alendronate Sodium Hydrate in 25 mL of 0.1 mol/L trisodium citrate TS, and use this solution as the sample stock solution. Pipet 5 mL of the sample stock solution, and add 0.1 mol/L trisodium citrate TS to make exactly 50 mL. Pipet 1 mL of this solution, add 0.1 mol/L trisodium citrate TS to make exactly 100 mL, and use this solution as the standard stock solution. To exactly 5 mL each of the sample stock solution and standard stock solution, add exactly 5 mL each of a solution of sodium tetraborate decahydrate (19 in 1000), acetonitrile and a solution of 9-fluorenylmethyl chloroformate in acetonitrile (1 in 250), shake for 45 seconds, and allow to stand for 30 minutes at room temperature. Then, add 20 mL of dichloromethane to them, shake for 60 seconds, centrifuge, and use the supernatant liquids so obtained as the sample solution and the standard solution, respectively. Perform the test with exactly 20 \(\mu\)L each of the sample solution and standard solution as directed under Liquid Chromatography (2.21) according to the following conditions. Determine each peak area of these solutions by the automatic integration method: each peak area other than alendronic acid obtained from the sample solution is not larger than the peak area of alendronic acid from the standard solution.

**Operating conditions**—

Detector: An ultraviolet absorption photometer (wavelength: 266 nm).

Column: A stainless steel column 4.1 mm in inside diameter and 25 cm in length, packed with styrene-divinylbenzene copolymer for liquid chromatography (10 \(\mu\)m in particle diameter).

Column temperature: A constant temperature of about 45°C.

Mobile phase A: Dissolve 2.94 g of trisodium citrate dihydrate and 1.42 g of anhydrous disodium hydrogen phosphate in 900 mL of water, adjust to pH 8.0 with phosphoric acid, and add water to make 1000 mL. To 850 mL of this solution add 150 mL of acetonitrile, and use this solution as the sample stock solution.

Mobile phase B: Dissolve 2.94 g of trisodium citrate dihydrate and 1.42 g of anhydrous disodium hydrogen phosphate in 900 mL of water, adjust to pH 8.0 with phosphoric acid, and add water to make 1000 mL. To 300 mL of this solution add 700 mL of acetonitrile, and use this solution as the standard stock solution.

Flowing of mobile phase: Control the gradient by mixing the mobile phases A and B as directed in the following table.

Time after injection of sample (min) | Mobile phase A (vol%) | Mobile phase B (vol%)
---|---|---
0 – 15 | 100 → 50 | 0 → 50
15 – 25 | 50 → 0 | 50 → 100

Flow rate: About 1.8 mL per minute.
Time span of measurement: About 5 times as long as the retention time of alendronic acid, beginning after the solvent peak.

System suitability—
System performance: Dissolve 15 mg of Alendronate Sodium Hydrate and 2 mg of 4-aminobutylic acid in 100 mL of 0.1 mol/L trisodium citrate TS. To 5 mL of this solution add 5 mL each of a solution of sodium tetraborate decahydrate (19 in 1000), acetonitrile and a solution of 9-fluorenylmethyl chloroformate in acetonitrile (1 in 250), then, proceed in the same manner as the sample solution. When the procedure is run with 20 μL of this solution under the above operating conditions, alendronic acid and 4-aminobutylic acid are eluted in this order with the resolution between these peaks being not less than 6.
System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of alendronic acid is not more than 2.0%.

(3) Residual solvent—Being specified separately.

Loss on drying 2.41 | 16.1 - 17.1% (1 g, 140°C, 3 hours).

Assay Weigh accurately about 10 mg each of Alendronate Sodium Hydrate and Alendronate Sodium RS (separately determine the loss on drying in the same conditions as Alendronate Sodium Hydrate), dissolve in 0.1 mol/L trisodium citrate TS to make exactly 100 mL, and use these solutions as the sample stock solution and the standard stock solution, respectively. To exactly 5 mL each of these solutions add exactly 5 mL each of a solution of sodium tetraborate decahydrate (19 in 1000) and a solution of 9-fluorenylmethyl chloroformate in acetonitrile (1 in 2000), shake for 30 seconds, and allow to stand for 25 minutes. Then, add 25 mL of dichloromethane, shake for 60 seconds, centrifuge, and use the supernatant liquids so obtained as the sample solution and the standard solution, respectively. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and determine the peak areas, A1 and A5, of alendronic acid.

Amount (mg) of alendronate sodium (C4H7N2NaO7P2)

\[ M_S = M_S \times \frac{A_1}{A_5} \]

M_S: Amount (mg) of Alendronate Sodium RS, calculated on the dried basis.

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 266 nm).
Column: A stainless steel column 4.1 mm in inside diameter and 25 cm in length, packed with styrene-divinylbenzene copolymer for liquid chromatography (10 μm in particle diameter).
Column temperature: A constant temperature of about 35°C.

Mobile phase: Dissolve 14.7 g of trisodium citrate dihydrate and 7.1 g of anhydrous disodium hydrogen phosphate in 900 mL of water, adjust to pH 8.0 with phosphoric acid, and add water to make 1000 mL. To 700 mL of this solution add 250 mL of acetonitrile for liquid chromatography and 50 mL of methanol.
Flow rate: Adjust the flow rate so that the retention time of alendronic acid is about 3 minutes.

System suitability—
System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of alendronic acid are not less than 1500 and not more than 1.5, respectively.
System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of alendronic acid is not more than 1.0%.

Containers and storage Containers—Tight containers.

Alendronate Sodium Injection
アレンドロン酸ナトリウム注射液

Alendronate Sodium Injection is an aqueous solution for injection.
It contains not less than 95.0% and not more than 101.0% of the labeled amount of alendronic acid (C4H7N2NaO7P2: 249.10).

Method of preparation Prepare as directed under Injections, with Alendronate Sodium Hydrate.

Description Alendronate Sodium Injection is a clear, colorless liquid.

Identification Use Alendronate Sodium Injection as the sample solution. Separate, dissolve 33 mg of alendronate sodium hydrate in 10 mL of water, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography (2.01) according to the following conditions, and determine the peak areas, A1 and A5, of alendronic acid.

Amount (mg) of alendronate sodium (C4H7N2NaO7P2)

\[ M_S = M_S \times \frac{A_1}{A_5} \]

M_S: Amount (mg) of Alendronate Sodium RS, calculated on the dried basis.

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 266 nm).

Alendronate Sodium Tablets

アレンドロン酸ナトリウム錠

Alendronate Sodium Tablets contain not less than 95.0% and not more than 105.0% of the labeled amount of alendronic acid (C$_{4}$H$_{13}$NO$_{7}$P$_{2}$: 249.10).

**Method of preparation** Prepare as directed under Tablets, with Alendronate Sodium Hydrate.

**Identification** To a quantity of powdered Alendronate Sodium Tablets, equivalent to 25 mg of alendronic acid (C$_{4}$H$_{13}$NO$_{7}$P$_{2}$) according to the labeled amount, add 25 mL of water, shake, centrifuge, and use the supernatant liquid as the sample solution. Separately, weigh 33 mg of alendronic acid hydrate, and dissolve in 25 mL of water as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography (2.0D). Spot 5 µL each of the sample solution and standard solution on a plate of cellulose for thin-layer chromatography. Develop the plate with a mixture of water, pyrigin, acetic acid (100) and ethyl acetate (1:1:1:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly a solution of ninhydrin in acetone (1 in 50) on the plate, and heat at 100°C for 10 minutes: the principal spots from the sample solution and standard solution show a blue-purple color and the same $R_f$ value.

**Uniformity of dosage units** (6.0D) Perform the test according to the following method: it meets the requirement of the content uniformity test.

To 1 tablet of Alendronate Sodium Tablets add 0.1 mol/L trisodium citrate TS to make exactly 100 mL, and stir until the tablet is completely disintegrated. Centrifuge this solution, pipet $V$ mL of the supernatant liquid, and add 0.1 mol/L trisodium citrate TS to make exactly $V$ mL so that each mL contains about 25 µg of alendronic acid (C$_{4}$H$_{13}$NO$_{7}$P$_{2}$), and use this solution as the sample stock solution. Then, proceed as directed in the Assay.

$$\text{Amount (mg) of alendronic acid (C}_4\text{H}_{13}\text{NO}_7\text{P}_2) = M_5 \times A_1 / A_5 \times 1/5 \times 0.919$$

$M_5$: Amount (mg) of Alendronate Sodium RS, calculated on the dried basis

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 265 nm).

Column: A stainless steel column 4.1 mm in inside diameter and 25 cm in length, packed with styrene-divinylbenzene copolymer for liquid chromatography (10 µm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: Dissolve 14.7 g of trisodium citrate dihydrate and 8.7 g of dipotassium hydrogen phosphate in 900 mL of water, adjust to pH 8.0 with phosphoric acid, and add water to make 1000 mL. To 750 mL of this solution add 200 mL of acetonitrile for liquid chromatography and 50 mL of methanol.

Flow rate: Adjust the flow rate so that the retention time of alendronic acid is about 7 minutes.

System suitability—

System performance: When the procedure is run with 50 µL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of alendronic acid are not less than 1500 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 50 µL of the standard solution under the above operating conditions, the relative standard deviation of the peak of alendronic acid is not more than 1.0%.

Containers and storage Container—Hermetic containers.

**Assay**

Weigh accurately and powder not less than 20 Alendronate Sodium Tablets. Weigh accurately a portion of the powder, equivalent to about 50 mg of alendronic acid (C\(_{4}H_{13}NO_{7}P_{2}\)), add 0.1 mol/L trisodium citrate TS to make exactly 1000 mL, stir for 30 minutes, and centrifuge. Pipet 5 mL of the supernatant liquid, add 0.1 mL/L trisodium citrate TS to make exactly 50 mL, and use this solution as the sample stock solution. Separately, weigh accurately about 39 mg of Alendronate Sodium RS (separately determine the loss on drying <2.41> in the same conditions as Alendronate Sodium Hydrate), dissolve in 0.1 mol/L trisodium citrate TS to make exactly 50 mL. Pipet 2 mL of this solution, add 0.1 mol/L trisodium citrate TS to make exactly 50 mL, and use this solution as the standard stock solution. Pipet 5 mL each of the sample stock solution and standard stock solution, add exactly 5 mL of a solution of sodium tetraborate decahydrate (19 in 500) and exactly 4 mL of a solution of 9-fluorenylmethyl chloroformate in acetonitrile (1 in 2000), shake for 30 seconds, and allow to stand at room temperature for 25 minutes. Then, add 25 mL of dichloromethane to them, shake for 45 seconds, centrifuge, and use the supernatant liquid as the sample solution and the standard solution, respectively. Perform the test with exactly 50 mL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine the peak areas, \( A_{T} \) and \( A_{S} \), of alendronic acid.

\[ M \times A_{T}/A_{S} \times 8/5 \times 0.919 \]

\( M \): Amount (mg) of Alendronate Sodium RS, calculated on the dried basis

**Operating conditions**

**Detector:** An ultraviolet absorption photometer (wavelength: 266 nm).

**Column:** A stainless steel column 4.1 mm in inside diameter and 25 cm in length, packed with styrene-divinylbenzene copolymer for liquid chromatography (10 \( \mu m \) in particle diameter).

**Column temperature:** A constant temperature of about 35°C.

Mobile phase: Dissolve 14.7 g of trisodium citrate dihydrate and 7.1 g of anhydrous disodium hydrogen phosphate in 900 mL of water, adjust to pH 8.0 with phosphoric acid, and add water to make 1000 mL. To 750 mL of this solution add 200 mL of acetonitrile for liquid chromatography and 50 mL of methanol.

Flow rate: Adjust the flow rate so that the retention time of alendronic acid is about 7 minutes.

**System suitability**

System performance: When the procedure is run with 50 \( \mu L \) of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of alendronic acid are not less than 1500 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 50 \( \mu L \) of the standard solution under the above operations conditions, the relative standard deviation of the peak of alendronic acid is not more than 1.0%.

**Containers and storage**

Container—Well-closed containers.

### Alimemazine Tartrate

アリメマジン酒石酸塩

![Chemical Structure](image)

(C\(_{18}H_{22}N_{2}S\))\(_{2}\).C\(_{4}H\(_{6}\)O\(_{6}\): 746.98

\( N/N,2\)-Trimethyl-3-(10H-phenothiazin-10-yl)propylamine hemitartrate

[41375-66-0]

Alimemazine Tartrate, when dried, contains not less than 98.0% of \( (C_{18}H_{22}N_{2}S)_{2}C_{4}H_{6}O_{6} \).

**Description**

Alimemazine Tartrate occurs as a white powder. It is odorless, and has a bitter taste.

It is freely soluble in water and in acetic acid (100), sparingly soluble in ethanol (95), and practically insoluble in diethyl ether.

The pH of a solution of Alimemazine Tartrate (1 in 50) is between 5.0 and 6.5.

It is gradually colored by light.

**Identification**

(1) To 2 mL of a solution of Alimemazine Tartrate (1 in 100) add 1 drop of iron (III) chloride TS: A red-brown color is produced, and immediately a yellow precipitate is formed.

(2) Dissolve 1 g of Alimemazine Tartrate in 5 mL of water, add 3 mL of sodium hydroxide TS, extract with two 10-mL portions of diethyl ether [use the aqueous layer obtained in the Identification (4)]. Shake the combined diethyl ether extracts with 3 g of anhydrous sodium sulfate, filter, and evaporate the diethyl ether with the aid of a current of air. Dry the residue in a desiccator (in vacuum, phosphorus oxide) for 16 hours: it melts <2.60> between 66°C and 70°C.

(3) Determine the absorption spectrum of a solution of
Alimemazine Tartrate (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(4) The aqueous layer, obtained in the identification (2), when neutralized with dilute acetic acid, responds to the Qualitative Tests <1.69> (1) and (2) for tartrate.

**Melting point** <2.60> 159 – 163°C

**Purity** (1) Clarity and color of solution—Dissolve 1.0 g of Alimemazine Tartrate in 20 mL of water: the solution is clear and colorless.

(2) Heavy metals <1.07>—Proceed with 1.0 g of Alimemazine Tartrate according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 2 ppm).

(3) Arsenic <1.17>—Prepare the test solution with 1.0 g of Alimemazine Tartrate according to Method 3, and perform the test. Use a solution of magnesium nitrate hexahydrate in ethanol (95) (1 in 5) (not more than 2 ppm).

**Loss on drying** <2.41> Not more than 0.5% (1 g, 105°C, 3 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.8 g of Alimemazine Tartrate, previously dried, dissolve in 50 mL of acetic acid (100), and titrate <2.50> with 0.1 mol/L perchloric acid VS until the color of the solution changes from red through brown to green-brown (indicator: 2 mL of p-naphtholbenzene TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 37.35 mg of (C₄H₄N₄O₂).₆C₂H₆O₄

**Containers and storage** Containers—Tight containers. Storage—Light-resistant.

### Allopurinol

アルポリノール

C₉H₈N₄O: 136.11
1H-Pyrazolo[3,4-d]pyrimidin-4-ol
[315-30-0]

Allopurinol, when dried, contains not less than 98.0% and not more than 101.0% of C₉H₈N₄O.

**Description** Allopurinol occurs as white to pale yellowish white crystals or crystalline powder.

It is slightly soluble in N,N-dimethylformamide, and very slightly soluble in water and in ethanol (99.5).

It dissolves in ammonia TS.

**Identification** (1) Determine the absorption spectrum of a solution of Allopurinol (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Allopurinol, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Purity** (1) Heavy metals <1.07>—Proceed with 1.0 g of Allopurinol according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(2) Arsenic <1.17>—Prepare the test solution with 1.0 g of Allopurinol according to Method 3, and perform the test (not more than 2 ppm).

(3) Related substances—Dissolve 50 mg of Allopurinol in 10 mL of ammonia TS, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add ammonia TS to make exactly 500 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 5 µL each of the sample solution and standard solution on a plate of cellulose with fluorescent indicator for thin-layer chromatography. Develop the plate with ammonia TS-saturated 1-butanol to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

**Loss on drying** <2.41> Not more than 0.5% (1 g, 105°C, 4 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.16 g of Allopurinol, previously dried, dissolve in 50 mL of acetic acid (100), and titrate <2.50> with 0.1 mol/L perchloric acid VS until the color of the solution changes from red through brown to green-brown (indicator: 2 mL of p-naphtholbenzene TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 13.61 mg of C₉H₈N₄O

**Containers and storage** Containers—Tight containers. Storage—Light-resistant.

### Allopurinol Tablets

アルポリノール錠

Allopurinol Tablets contain not less than 93.0% and not more than 107.0% of the labeled amount of allopurinol (C₉H₈N₄O: 136.11).

**Method of preparation** Prepare as directed under Tablets, with Allopurinol.

**Identification** (1) Determine the absorption spectrum of the sample solution obtained in the Assay as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits a maximum between 248 nm and 252 nm.

(2) To a quantity of powdered Allopurinol Tablets,
equivalent to 0.1 g of Allopurinol according to the labeled amount, add 5 mL of a solution of diethylamine (1 in 10), shake well, add 5 mL of methanol, centrifuge, and use the supernatant liquid as the sample solution. Separately, dissolve 0.1 g of allopurinol in 5 mL of a solution of diethylamine (1 in 10), add 5 mL of methanol, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography 2.2.4. Spot 2.5 μL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of 2-butanol, ammonia solution (28) and 2-methoxyethanol (3:1:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the principal spots obtained from the sample solution and standard solution show the same Rf value.

Uniformity of dosage units 6.02 Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Allopurinol Tablets add V/10 mL of a 0.05 mol/L sodium hydroxide TS, shake well, and treat with ultrasonic waves for 10 minutes. After cooling, add 0.1 mol/L hydrochloric acid TS to make exactly V mL so that each mL contains about 0.5 mg of allopurinol (C₆H₄N₄O), and filter through a membrane filter with a pore size not exceeding 0.8 μm. Discard the first 10 mL of the filtrate, pipet 2 mL of the subsequent filtrate, add 0.1 mol/L of hydrochloric acid TS to make exactly 100 mL, and use this solution as the sample solution. Separately, weigh accurately about 0.1 g of allopurinol for assay, previously dried at 105°C for 4 hours, dissolve in 20 mL of 0.05 mol/L sodium hydroxide TS, and add 0.1 mol/L hydrochloric acid TS to make exactly 100 mL. Pipet 2 mL of this solution, add 0.1 mol/L hydrochloric acid TS to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, A₁ and A₅, of the sample solution and standard solution at 250 nm as directed under Ultraviolet-visible Spectrophotometry 2.2.4.

\[
\text{Amount (mg) of allopurinol (C₆H₄N₄O)} = M₅ \times A₁ / A₅ \times V / 100
\]

\[ M₅: \text{Amount (mg) of allopurinol for assay} \]

Dissolution 6.10 When the test is performed at 50 revolutions per minute according to the Paddle method, using 900 mL of water as the dissolution medium, the dissolution rate in 30 minutes of Allopurinol Tablets is not less than 80%.

Start the test with 1 tablet of Allopurinol Tablets, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.8 μm. Discard the first 10 mL of the filtrate, pipet V mL of the subsequent filtrate, add water to make exactly V mL so that each mL contains about 11 μg of allopurinol (C₆H₄N₄O) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 11 mg of allopurinol for assay, previously dried at 105°C for 4 hours, and dissolve in water to make exactly 100 mL. Pipet 5 mL of this solution, add water to make exactly 50 mL, and use this solution as the standard solution. Determine the absorbances, A₁ and A₅, of the sample solution and standard solution at 250 nm as directed under Ultraviolet-visible Spectrophotometry 2.2.4.

\[
\text{Dissolution rate (％) with respect to the labeled amount of allopurinol (C₆H₄N₄O)} = M₅ \times A₁ / A₅ \times V / V \times 1 / C \times 90
\]

\[ M₅: \text{Amount (mg) of allopurinol for assay} \]

C: Labeled amount (mg) of allopurinol (C₆H₄N₄O) in 1 tablet

Assay Weigh accurately the mass of not less than 20 Allopurinol Tablets, and powder. Weigh accurately a portion of the powder, equivalent to about 0.1 g of allopurinol (C₆H₄N₄O), add 20 mL of 0.05 mol/L sodium hydroxide TS, shake well, and treat with ultrasonic waves for 10 minutes. After cooling, add 0.1 mol/L hydrochloric acid TS to make exactly 200 mL, and filter through a membrane filter with a pore size not exceeding 0.8 μm. Discard the first 10 mL of the filtrate, pipet 2 mL of the subsequent filtrate, add 0.1 mol/L hydrochloric acid TS to make exactly 100 mL, and use this solution as the sample solution. Separately, weigh accurately about 0.1 g of allopurinol for assay, previously dried at 105°C for 4 hours, dissolve in 20 mL of 0.05 mol/L sodium hydroxide TS, and add 0.1 mol/L hydrochloric acid TS to make exactly 200 mL. Pipet 2 mL of this solution, add 0.1 mol/L hydrochloric acid TS to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, A₁ and A₅, of the sample solution and standard solution at 250 nm as directed under Ultraviolet-visible Spectrophotometry 2.2.4.

\[
\text{Amount (mg) of allopurinol (C₆H₄N₄O)} = M₅ \times A₁ / A₅
\]

\[ M₅: \text{Amount (mg) of allopurinol for assay} \]

Containers and storage Containers—Well-closed containers.

Alminoprofen

アルミノプロフェン

C₁₃H₁₇NO₂: 219.28
(2RS)-2-[[4-(2-Methylprop-2-en-1-yl)amino]phenyl]propanoic acid [39718-89-3]

Alminoprofen, when dried, contains not less than 99.0% and not more than 101.0% of C₁₃H₁₇NO₂.

Description Alminoprofen occurs as white to pale yellow crystals or crystalline powder.

It is freely soluble in ethanol (99.5) and in acetic acid (100), and very slightly soluble in water.

It gradually turns brown on exposure to light.

A solution of Alminoprofen in ethanol (99.5) (1 in 10) shows no optical rotation.

Identification (1) Determine the absorption spectrum of a solution of Alminoprofen in ethanol (99.5) (3 in 500,000) as directed under Ultraviolet-visible Spectrophotometry 2.2.4, and compare the spectrum with the Reference Spectrum:
both spectra exhibit similar intensities of absorption at the same wave numbers.

(2) Determine the infrared absorption spectrum of Alminoprofen as directed in the potassium bromide disk method under Infrared Spectrophotometry \(<2.25>\), and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Melting point** \(<2.60>\) 106 – 108°C

**Purity** (1) Heavy metals \(<1.07>\)—Proceed with 2.0 g of Alminoprofen according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(2) Arsenic \(<1.11>\)—Prepare the test solution with 1.0 g of Alminoprofen according to Method 3, and perform the test (not more than 2 ppm).

(3) Related substances—Conduct this procedure using light-resistant vessels. Dissolve 50 mg of Alminoprofen in 100 mL of the mobile phase, and use this solution as the sample solution. Pipet 2 mL of the sample solution, add the mobile phase to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 5 \(\mu\)L each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01>\) according to the following conditions. Determine each peak area of these solutions by the automatic integration method: the area of the peak other than alminoprofen obtained from the sample solution is not larger than 1/5 times the peak area of alminoprofen from the standard solution. Furthermore, the total area of the peaks other than alminoprofen from the sample solution is not larger than the peak area of alminoprofen from the standard solution.

**Operating conditions**—
- **Detector:** An ultraviolet absorption photometer (wavelength: 254 nm).
- **Column:** A stainless steel column 6.0 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 \(\mu\)m in particle diameter).
- **Column temperature:** A constant temperature of about 25°C.
- **Mobile phase:** A mixture of methanol and diluted acetic acid (100) (1 in 1000) (4:1).
- **Flow rate:** Adjust the flow rate so that the retention time of alminoprofen is about 5 minutes.
- **Time span of measurement:** About 5 times as long as the retention time of alminoprofen, beginning after the solvent peak.

**System suitability**—
- **Test for required detectability:** Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 10 mL. Confirm that the peak area of alminoprofen obtained from 5 \(\mu\)L of this solution is equivalent to 7 to 13% of that from 5 \(\mu\)L of the standard solution.
- **System performance:** Dissolve 10 mg each of Alminoprofen and butyl parahydroxybenzoate in 100 mL of methanol. Pipet 10 mL of this solution, and add methanol to make exactly 50 mL. When the procedure is run with 5 \(\mu\)L of this solution under the above operating conditions, alminoprofen and butyl parahydroxybenzoate are eluted in this order with the resolution between these peaks being not less than 2.0.
- **System repeatability:** When the test is repeated 6 times with 5 \(\mu\)L of the standard solution under the above operating conditions, the relative standard deviation of the peak area of alminoprofen is not more than 2.0%.

**Loss on drying** \(<2.41>\) Not more than 0.5% (1 g, in vacuum, phosphorus (V) oxide, 1 hour).

**Residue on ignition** \(<2.44>\) Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.3 g of Alminoprofen, previously dried, dissolve in 50 mL of acetic acid (100), and titrate \(<2.50>\) with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

\[
\text{Each mL of 0.1 mol/L perchloric acid VS} = 21.93 \text{ mg of C}_{13}H_{17}NO_2
\]

**Containers and storage** Containers—Well-closed containers. Storage—Light-resistant.

### Alminoprofen Tablets

アルミノプロフェン錠

Alminoprofen Tablets contain not less than 93.0% and not more than 107.0% of the labeled amount of alminoprofen (\(\text{C}_{13}H_{17}NO_2\): 219.28).

**Method of preparation** Prepare as directed under Tablets, with Alminoprofen.

**Identification** Take an amount of powdered Alminoprofen Tablets, equivalent to 30 mg of Alminoprofen according to the labeled amount, add ethanol (99.5) to make 100 mL, shake thoroughly, and centrifuge. To 2 mL of the supernatant liquid add ethanol (99.5) to make 100 mL, and determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry \(<2.24>\): it exhibits maxima between 253 nm and 257 nm, and between 298 nm and 302 nm.

**Purity** Related substances—Conduct this procedure using light-resistant vessels. Powder 10 tablets of Alminoprofen Tablets, weigh a portion of the powder equivalent to 50 mg of Alminoprofen according to the labeled amount, add 50 mL of the mobile phase, shake for 15 minutes, add the mobile phase to make exactly 100 mL, centrifuge, and use the supernatant liquid as the sample solution. Pipet 2 mL of the sample solution, add the mobile phase to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 5 \(\mu\)L each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01>\) according to the conditions described in the Purity (3) under Alminoprofen. Determine each peak area of each solution by the automatic integration method: the area of the peak other than alminoprofen obtained from the sample solution is not larger than 1/2 times the peak area of alminoprofen from the standard solution. Furthermore, the total area of the peaks other than alminoprofen from the sample solution is not larger than 2 times the peak area of alminoprofen from the standard solution.

**Uniformity of dosage units** \(<6.02>\) Perform the test according to the following method: it meets the requirement of the Content uniformity test.
To 1 tablet of Alminoprofen Tablets add 5 mL of water, shake until the tablet is disintegrated, add 50 mL of ethanol (99.5), shake for 20 minutes, then add ethanol (99.5) to make exactly 100 mL, and centrifuge. Pipet 3 mL of the supernatant liquid, add ethanol (99.5) to make exactly 50 mL. Pipet V mL of this solution, add ethanol (99.5) to make exactly V mL so that each mL contains about 6 μg of alminoprofen (C₁₃H₁₇NO₂), and use this solution as the sample solution. Then, proceed as directed in the Assay.

Amount (mg) of alminoprofen (C₁₃H₁₇NO₂) = Mₛ × A₁/Aₙ × V/V × 1/3

Mₛ: Amount (mg) of alminoprofen for assay

Dissolution [6.10] When the test is performed at 50 revolutions per minute according to the Paddle method, using 900 mL of 2nd fluid for dissolution test as the dissolution medium, the dissolution rate in 45 minutes of Alminoprofen Tablets is not less than 80%.

Start the test with 1 tablet of Alminoprofen Tablets, withdraw not less than 20 mL of the medium at specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.45 μm. Discard the first 10 mL of the filtrate, pipet V mL of the subsequent filtrate, add 0.05 mol/L sodium hydroxide TS to make exactly V mL so that each mL contains about 8.9 μg of alminoprofen (C₁₃H₁₇NO₂) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 30 mg of alminoprofen for assay, previously dried in vacuum for 1 hour using phosphorus (V) oxide as the desiccant, and dissolve in 0.05 mol/L sodium hydroxide TS to make exactly 100 mL. Pipet 3 mL of this solution, add 0.05 mol/L sodium hydroxide TS to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, A₁ and Aₙ, at 245 nm of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry <2.24>.

Dissolution rate (%) with respect to the labeled amount of alminoprofen (C₁₃H₁₇NO₂) = Mₛ × A₁/Aₙ × V/V × 1/C × 27

Mₛ: Amount (mg) of alminoprofen for assay

C: Labeled amount (mg) of alminoprofen (C₁₃H₁₇NO₂) in 1 tablet

Assay Weigh accurately the mass of not less than 20 tablets of Alminoprofen Tablets, and powder. Weigh accurately an amount equivalent to about 60 mg of alminoprofen (C₁₃H₁₇NO₂), add ethanol (99.5) and shake well, add ethanol (99.5) to make exactly 200 mL, and centrifuge. Pipet 2 mL of the supernatant liquid, add ethanol (99.5) to make exactly 100 mL, and use this solution as the sample solution. Separately, weigh accurately about 30 mg of alminoprofen for assay, previously dried in vacuum for 1 hour using phosphorus (V) oxide as the desiccant, dissolve in ethanol (99.5) to make exactly 100 mL. Pipet 2 mL of this solution, add ethanol (99.5) to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, A₁ and Aₙ, at the wavelength of maximum absorption at about 255 nm of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry <2.24>.

Amount (mg) of alminoprofen (C₁₃H₁₇NO₂) = Mₛ × A₁/Aₙ × 2

Mₛ: Amount (mg) of alminoprofen for assay

Containers and storage Containers—Well-closed containers.

Alprazolam

アルプラゾラム

C₁₇H₁₃ClN₄: 308.76
8-Chloro-1-methyl-6-phenyl-4-
[1,2,4]triazolo[4,3-]
H: 4H-
[1,2,4]triazolo[4,3-a]1,4benzdiazepine
[28981-97-7]

Alprazolam, when dried, contains not less than 98.5% of C₁₇H₁₃ClN₄.

Description Alprazolam occurs as white crystals or crystaline powder.

It is freely soluble in chloroform, soluble in methanol and in ethanol (95), sparingly soluble in acetic anhydride, and practically insoluble in water.

It dissolves in dilute nitric acid.

Identification (1) Determine the absorption spectrum of a solution of Alprazolam in ethanol (95) (1 in 200,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Dissolve 0.05 g of Alprazolam in 0.7 mL of deuterchloroform for nuclear magnetic resonance spectroscopy, and determine the spectrum of this solution using tetramethylsilane for nuclear magnetic resonance spectroscopy as an internal reference compound, as directed under Nuclear Magnetic Resonance Spectroscopy <2.21> (H): it exhibits a single signal A at around δ 2.6 ppm, doublet signals B and C at around δ 4.0 ppm and δ 5.4 ppm, and a broad signal D between δ 7.1 ppm and 7.9 ppm. The ratio of integrated intensity of each signal, A:B:C:D, is about 3:1:1:8.

(3) Perform the test with Alprazolam as directed under Flame Coloration Test <1.04> (2): a green color appears.

Melting point <2.60> 228 – 232°C

Purity (1) Chloride <1.02>—Dissolve 0.5 g of Alprazolam in 10 mL of dilute nitric acid, and add water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 0.20 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.014%).

(2) Heavy metals <1.07>—Proceed with 2.0 g of Alprazolam according to Method 4, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(3) Related substances—Dissolve 50 mg of Alprazolam in 10 mL of methanol, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add methanol to
make exactly 100 mL, then pipet 1 mL of this solution, add methanol to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 20 \( \mu \text{L} \) each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop with a mixture of acetone, hexane, ethyl acetate and ethanol (95) (4:2:2:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

**Loss on drying** <2.41> Not more than 0.5% (1 g, reduced pressure not exceeding 0.67 kPa, 60°C, 4 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.25 g of Alprazolam, previously dried, dissolve in 100 mL of acetic anhydride, and titrate <2.50> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 15.44 mg of C\(_{17}\)H\(_{13}\)ClN\(_4\).

**Containers and storage** Containers—Well-closed containers.

---

**Alprenolol Hydrochloride**

アルプレノール塩酸塩

\[
\text{C}_{15}\text{H}_{23}\text{NO}_{2}\cdot\text{HCl}: 285.81
\]

(2R,5S)-1-(2-Allylphenox)-3-[1-(methylamino)propan-2-ol monohydrochloride [13707-88-5]

Alprenolol Hydrochloride, when dried, contains not less than 99.0% of C\(_{15}\)H\(_{23}\)NO\(_2\)\cdot\text{HCl}.

**Description** Alprenolol Hydrochloride occurs as white crystals or crystalline powder.

It is freely soluble in water, in ethanol (95) and in acetic acid (100), slightly soluble in acetic anhydride, and practically insoluble in diethyl ether.

**Identification (1)** To 2 mL of a solution of Alprenolol Hydrochloride (1 in 100) add 0.05 mL of copper (II) sulfate TS and 2 mL of sodium hydrosulfite: a blue-purple color develops. To this solution add 1 mL of diethyl ether, shake well, and allow to stand: a red-purple color develops in the diethyl ether layer.

(2) Dissolve 0.05 g of Alprenolol Hydrochloride in 5 mL of water, add 1 to 2 drops of bromine TS, and shake: the color of the test solution disappears.

(3) Determine the absorption spectrum of a solution of Alprenolol Hydrochloride in ethanol (95) (1 in 10,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(4) Determine the infrared absorption spectrum of Alprenolol Hydrochloride, previously dried, as directed in the potassium chloride disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(5) A solution of Alprenolol Hydrochloride (1 in 50) responds to the Qualitative Tests <1.99> for chloride.

**pH** <2.54> Dissolve 1.0 g of Alprenolol Hydrochloride in 10 mL of water: the pH of this solution is between 4.5 and 6.0.

**Melting point** <2.60> 108 – 112°C

**Purity (1)** Clarity and color of solution—Dissolve 1.0 g of Alprenolol Hydrochloride in 10 mL of water: the solution is clear and colorless.

(2) Heavy metals <1.07>—Proceed with 2.0 g of Alprenolol Hydrochloride according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(3) Arsenic <1.11>—Prepare the test solution with 1.0 g of Alprenolol Hydrochloride according to Method 3, and perform the test (not more than 2 ppm).

(4) Related substances—Dissolve 0.10 g of Alprenolol Hydrochloride in 10 mL of ethanol (95), and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add ethanol (95) to make exactly 100 mL. Pipet 2.5 mL of this solution, add ethanol (95) to make exactly 10 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 10 \( \mu \text{L} \) each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of dichloromethane, acetone, acetic acid (100) and water (60:42:5:3) to a distance of about 10 cm, air-dry the plate, and then dry at 80°C for 30 minutes. After cooling, allow the plate to stand in iodine vapor for 30 minutes: the spots other than the principal spot and the spot on the starting point from the sample solution are not more intense than the spot from the standard solution.

**Loss on drying** <2.41> Not more than 0.5% (1 g, in vacuum, silica gel, 4 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.5 g of Alprenolol Hydrochloride, previously dried, dissolve in 50 mL of a mixture of acetic anhydride and acetic acid (100) (7:3), and titrate <2.50> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 28.58 mg of C\(_{15}\)H\(_{23}\)NO\(_2\)\cdot\text{HCl}

**Containers and storage** Containers—Well-closed containers.
Alprostadil

Prostaglandin E₁

アルプロスタジル

\[
\begin{align*}
\text{C}_{20}\text{H}_{34}\text{O}_5: 354.48 \\
7-[1(R,2R,3R)-3-Hydroxy-2-[(1E,3S)-3-hydroxyoct-1-en-1-yl]-5-oxocyclopentyl]heptanoic acid [745-65-3]
\end{align*}
\]

Alprostadil, when dried, contains not less than 97.0% and not more than 103.0% of \( \text{C}_{20}\text{H}_{34}\text{O}_5 \).

**Description**

Alprostadil occurs as white crystals or crystaline powder.

It is freely soluble in ethanol (99.5) and in tetrahydrofuran, slightly soluble in acetonitrile, and practically insoluble in water.

**Identification (1)**

The absorption spectrum of a solution of Alprostadil in ethanol (99.5) (1 in 100,000) determined as directed under Ultraviolet-visible Spectrophotometry shows no absorption between 210 nm and 350 nm. Separately, to 10 mL of this solution add 1 mL of potassium hydroxide-ethanol TS, allow to stand for 15 minutes, and determine the absorption spectrum in the same way. Compare the spectrum so obtained with the Reference Spectrum or the spectrum of a solution of Alprostadil RS prepared in the same manner as the sample solution: both spectra exhibit similar intensities of absorption at the same wavelengths.

**(2)**

Determine the infrared absorption spectrum of Alprostadil, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry, and compare the spectrum with the Reference Spectrum or the spectrum of previously dried Alprostadil RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Optical rotation**

\[ [\alpha]_{D}^{20}: -53 \text{ to } -61^\circ \text{ (after drying, 25 mg, tetrahydrofuran, 5 mL, 100 mm).} \]

**Melting point**

\[ \text{114} \text{ – 118}^\circ \text{C} \]

**Purity**

Related substances—Dissolve 4 mg of Alprostadil in 2 mL of a mixture of acetonitrile for liquid chromatography and water (9:1), and use this solution as the sample solution. Pipet 0.5 mL of the sample solution, and add the mixture of acetonitrile for liquid chromatography and water (9:1) to make exactly 10 mL. Pipet 2 mL of this solution, add the mixture of acetonitrile for liquid chromatography and water (9:1) to make exactly 10 mL, and use this solution as the standard solution. Perform the test with exactly 5 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and determine each peak area by the automatic integration method: the area of the peaks, having the relative retention time of about 0.70 and 1.26 with respect to alprostadil, is not larger than 1/2 times the peak area of alprostadil with the standard solution, the area of the peaks, having the relative retention time of about 0.88 and 1.18 with respect to alprostadil, is not larger than the peak area of alprostadil with the standard solution, the area of the peaks other than alprostadil and the peaks mentioned above is not larger than 1/10 times the peak area of alprostadil with the standard solution and the total area of the peaks other than alprostadil is not larger than 2 times the peak area of alprostadil with the standard solution.

**Operating conditions**

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay.

Time span of measurement: About 5 times as long as the retention time of alprostadil beginning after the solvent peak.

**System suitability**

Test for required detectability: Measure exactly 2 mL of the standard solution, add the mixture of acetonitrile for liquid chromatography and water (9:1) to make exactly 20 mL. Confirm that the peak area of alprostadil obtained with 5 \( \mu L \) of this solution is equivalent to 7 to 13% of that with 5 \( \mu L \) of the standard solution.

System performance: Proceed as directed in the system suitability in the Assay.

**System repeatability:** When the test is repeated 6 times with 5 \( \mu L \) of the standard solution under the above operating conditions, the relative standard deviation of the peak area of alprostadil is not more than 1.5%.

**Loss on drying**

\[ \text{Not more than 1.0% (0.1 g, in vacuum, phosphorus (V) oxide, 4 hours).} \]

**Assay**

Weigh accurately about 5 mg each of Alprostadil and Alprostadil RS, previously dried, dissolve in exactly 5 mL of the internal standard solution, add a mixture of acetonitrile for liquid chromatography and water (9:1) to make 50 mL, and use these solutions as the sample solution and standard solution, respectively. Perform the test with 5 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and calculate the ratios, \( Q_{al} \) and \( Q_{RS} \), of the peak area of alprostadil to that of the internal standard.

Amount (mg) of \( \text{C}_{20}\text{H}_{34}\text{O}_5 \) = \( M_{S} \times Q_{al}/Q_{RS} \)

\( M_{S}: \) Amount (mg) of Alprostadil RS

**Internal standard solution**

A solution of dimethyl phthalate in the mixture of acetonitrile for liquid chromatography and water (9:1) (1 in 10,000).

**Operating conditions**

Detector: An ultraviolet absorption photometer (wavelength: 196 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadeclsilanized silica gel for liquid chromatography (5 \( \mu m \) in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: Dissolve 9.07 g of potassium dihydrogen phosphate in water to make 1000 mL. Adjust the pH to 6.3 with a solution prepared by dissolving 9.46 g of disodium hydrogen phosphate in water to make 1000 mL, and dilute to 10 times its volume with water. To 360 mL of this solution add 110 mL of acetonitrile for liquid chromatography and
30 mL of methanol for liquid chromatography.
Flow rate: Adjust the flow rate so that the retention time of alprostadil is about 10 minutes.

System suitability—

System performance: When the procedure is run with 5 µL of the standard solution under the above operating conditions, alprostadil and the internal standard are eluted in this order with the resolution between these peaks being not less than 9.
System repeatability: When the test is repeated 6 times with 5 µL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of alprostadil to that of the internal standard is not more than 1.0%.

Containers and storage—Containers—Tight containers.
Storage—Light-resistant, and at a temperature not exceeding 5°C.

Alprostadil Injection
アルプロスタジル注射液

Alprostadil Injection is an emulsion-type injection. It contains not less than 80.0% and not more than 125.0% of the labeled amount of alprostadil (C_{20}H_{34}O_{5}: 354.48).

Method of preparation—Prepare as directed under Injections, with Alprostadil.

Description—Alprostadil Injection occurs as a white emulsion and is slightly viscous. It has a distinctive odor.

Identification—To a quantity of Alprostadil Injection, corresponding to 10 µg of Alprostadil according to the labeled amount, add 2 mL of acetonitrile, shake well, and centrifuge. To 3.5 mL of the supernatant liquid add 7 mL of diluted phosphoric acid (1 in 1000), and then run this solution on a column (prepared by filling a 10 mm inside diameter, 9 mm long chromatography tube with 0.4 g of 70 µm octadecylsilanized silica gel for pretreatment) previously having undergone elution with 2.5 mL of a mixture of methanol and then 10 mL of water. Wash the octadecylsilanized silica gel for pretreatment) prewashed layer Chromatography

Separately, dissolve 1 mg of Alprostadil RS in 10 mL of ethyl acetate, and use this solution as the sample solution.

Purity—(1) Heavy metals (≤1.07)—Proceed with 4.0 mL of Alprostadil Injection according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 5 ppm).
(2) Prostaglandin A₁—Use the sample solution obtained in the Assay as the sample solution. Separately, weigh accurately about 10 mg of prostaglandin A₁, previously dried for 4 hours in a desiccator (in vacuum, phosphorus (V) oxide), and dissolve in ethanol (99.5) to make exactly 100 mL. Pipet 2.5 mL of this solution, and add the mobile phase to make exactly 50 mL. Pipet 1 mL of this solution, add exactly 1 mL of the internal standard solution, and use this solution as the standard solution. Perform the test with 40 µL each of the sample solution and standard solution as directed under Liquid Chromatography (≤2.01>) according to the following conditions, calculate the ratios, Q₁ and Q₂, of the peak area of prostaglandin A₁ to that of the internal standard, and calculate the amount of prostaglandin A₁ converted to alprostadil using the following equation: not more than 3.0 µg per a volume, equivalent to 5 µg of alprostadil (C_{20}H_{32}O_{5}).

Amount (µg) of prostaglandin A₁ (C_{20}H_{32}O_{5}) converted to alprostadil
\[ M_{\text{A₁}} \times Q_{1}/Q_{2} \times 1/2 \times 1.054 \]

M_{\text{A₁}}: Amount (mg) of prostaglandin A₁

Internal standard solution—Dissolve 50 mg of 1-naphthol in 20 mL of ethanol (99.5). To 3 mL of this solution add the mobile phase to make 100 mL.

Operating conditions—Proceed as directed in the operating conditions in the Assay.

System suitability—
Test for required detectability: To exactly 1 mL of the standard solution add the mobile phase to make exactly 5 mL. Confirm that the peak area of prostaglandin A₁ obtained with 40 µL of this solution is equivalent to 14 to 26% of that with 40 µL of the standard solution.

System performance, and system repeatability: Proceed as directed in the system suitability in the Assay.

(3) Peroxide—Pipet 4 mL of Alprostadil Injection, place in a glass-stoppered flask, add 15 mL of a mixture of acetic acid (100) and isooctane (3:2), previously having undergone a 30 minute nitrogen substitution, and dissolve with gentle shaking. To this solution add 0.5 mL of saturated potassium iodide TS, replace the inside of the vessel with nitrogen, and shake for exactly 5 minutes. Then, add 0.5 mL of starch TS, shake vigorously, add 15 mL of water, and shake vigorously. Under a stream of nitrogen, titrate (≤2.50>) with 0.01 mol/L sodium thiosulfate VS until the color of the solution disappears. Separately, perform a blank determination using 4 mL of water, and make any necessary correction. Calculate the amount of peroxides using the following equation: not more than 0.5 meq/L.

Amount (meq/L) of peroxides = V × 2.5

V: Amount (mL) of 0.01 mol/L sodium thiosulfate VS consumed

(4) Free fatty acids—Pipet 3 mL of Alprostadil Injection, add exactly 15 mL of a mixture of 2-propanol, heptane and 0.5 mol/L sulfuric acid TS (40:10:1), and shake for 1 minute. After leaving for 10 minutes, add exactly 9 mL of heptane and exactly 9 mL of water, shake the test tube by in-
Amount (meq/L) of free fatty acids = \( V_f / V_s \times f \times 15 \)

**Bacterial endotoxins** &lt;4.00 &gt; Less than 10 EU/mL.

**Extractable volume** &lt;6.00 &gt; It meets the requirement.

**Foreign insoluble matter** &lt;6.00 &gt; Perform the test according to Method 1: no easily detectable foreign matter is observed.

**Sterility** &lt;4.06 &gt; Perform the test according to the Membrane filter method: it meets the requirement. However, use the sample solution consisting of equal volume of Alprostadil Injection and a solution prepared by adding water to 0.1 g of polysorbate 80 to make 100 mL.

**Particle diameter** Being specified separately.

**Assay** Measure exactly a volume of Alprostadil Injection corresponding to 5 mg of alprostadil (C20H34O5), add exactly 1 mL of the internal standard solution, shake, and use this solution as the sample solution. Separately, weigh accurately about 5 mg of Alprostadil RS, previously dried in a desiccator (in vacuum, phosphorus (V) oxide) for 4 hours, dissolve in ethanol (99.5) to make exactly 50 mL, and use this solution as standard stock solution. Pipet 2.5 mL of the standard stock solution, add the mobile phase to make exactly 50 mL, pipet 1 mL, add exactly 1 mL of the internal standard solution, and use this solution as the standard solution. Perform the test with 40 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography &lt;2.01 &gt; according to the following conditions using an apparatus equipped with an automatic pretreatment device (using a postcolumn reaction), and calculate the ratios, \( Q_f \) and \( Q_s \), of the peak area of alprostadil to that of the internal standard.

\[
\text{Amount (\( \mu g \)) of alprostadil (C20H34O5) = } M_s \times \frac{Q_f}{Q_s} 
\]

\[
M_C = \text{Amount (mg) of Alprostadil RS}
\]

**Internal standard solution**—Dissolve 50 mg of 1-naphthol in 20 mL of ethanol (99.5). To 3 mL of this solution add 90 mL of the mobile phase to make 100 mL.

**Operating conditions**—

Equipment: Liquid chromatograph consisting of 2 pumps for pumping the mobile phase and the reaction reagent, an automatic pretreatment device, column, reaction coil, detector, and recording apparatus. Use a reaction coil that is maintained at a constant temperature.

Detector: An ultraviolet absorption photometer (wavelength: 278 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 \( \mu m \) in particle diameter).

Column temperature: A constant temperature of about 60°C.

Reaction coil: Polytetrafluoroethylene tube 0.5 mm in inside diameter and 10 m in length.

Mobile phase: Dissolve 9.07 g of potassium dihydrogen phosphate in water to make 1000 mL and adjust the pH to 6.3 by adding a solution prepared by dissolving 9.46 g of disodium hydrogen phosphate in water to make 1000 mL. To 1 volume of this solution add 9 volumes of water. To 3 volumes of this solution add 1 volume of acetonitrile for liquid chromatography.

Reaction reagent: Potassium hydroxide TS.

Reaction temperature: A constant temperature of about 60°C.

Mobile phase flow rate: Adjust the flow rate so that the retention time of alprostadil is about 7 minutes.

Reaction reagent flow rate: 0.5 mL per minute.

Automatic pretreatment device: Composed of a pretreatment column, pump for pumping pretreatment column wash solution, and routing valve for 2 high pressure flow paths.

Pretreatment column: A stainless steel column 4 mm in inside diameter and 2.5 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 \( \mu m \) in particle diameter).

Pretreatment column wash solution: Ethanol (99.5).

Flow rate of wash solution: A constant flow rate of about 2.0 mL per minute.

Flow path operating conditions: Change the flow path operating conditions at the times shown in the table below using the valves shown in the figure.

Alprostadil Alfadex / Official Monographs

**Prostaglandin E₁ α-Cyclodextrin Clathrate Compound**

アルプロスタジル アルファデクス

C₂₀H₃₄O₅·αC₃₆H₆₀O₃₀
7-[(1R,2R,3R)-3-Hydroxy-2-[(1E,3S)-3-hydroxyoct-1-en-1-yl]-5-oxocyclopentyl]heptanoic acid—α-cyclodextrin [55648-20-9]

Alprostadil Alfadex is a α-cyclodextrin clathrate compound of alprostadil.

It contains not less than 2.8% and not more than 3.2% of alprostadil (C₂₀H₃₄O₅: 354.48), calculated on the anhydrous basis.

**Description**

Alprostadil Alfadex occurs as a white powder.

It is freely soluble in water, and practically insoluble in ethanol (95), in ethyl acetate and in diethyl ether.

It is hygroscopic.

**Identification (1)**

Dissolve 0.02 g of Alprostadil Alfadex in 5 mL of water, add 5 mL of ethyl acetate, shake, and centrifuge. Use the supernatant liquid as the sample solution (1). Separately, to 0.02 g of Alprostadil Alfadex add 5 mL of ethyl acetate, shake, and centrifuge. Use the supernatant liquid as the sample solution (2). Evaporate the solvent from these solutions under reduced pressure, add 2 mL of sulfuric acid to the residue, and shake for 5 minutes: the liquid obtained from the sample solution (1) shows an orange-yellow color, while the liquid obtained from the sample solution (2) does not show that color.

**Identification (2)**

Dissolve 0.02 g of Alprostadil Alfadex in 5 mL of water, add 5 mL of ethyl acetate, shake, and centrifuge, and evaporate the solvent from the supernatant liquid under reduced pressure. Dissolve the residue in 2 mL of ethanol (95), add 5 mL of 1,3-dinitrobenzene TS, then add 5 mL of a solution of potassium hydroxide in ethanol (95) (17 in 100) under ice-cooling, and allow to stand for 20 minutes in a dark place under ice-cooling: a purple color develops.

**Identification (3)**

Dissolve 0.05 g of Alprostadil Alfadex in 1 mL of iodine TS, by heating on a water bath, and allow to stand: a dark blue precipitate is formed.

**Identification (4)**

Determine the absorption spectrum of a solution of Alprostadil Alfadex in dilute ethanol (3 in 10,000) as directed under Ultraviolet-visible Spectrophotometry <2,24>: it exhibits no absorption between 220 nm and 400 nm. Separately, to 10 mL of the solution add 1 mL of potassium hydroxide-ethanol TS, allow to stand for 15 minutes, and determine the absorption spectrum as directed under Ultraviolet-visible Spectrophotometry <2,24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

**System suitability**

System performance: Dissolve 10 mg of prostaglandin A₁, previously dried in a desiccator (in vacuum, phosphorus (V) oxide) for 4 hours, in ethanol (99.5) to make 100 mL. To 2.5 mL of this solution add 2.5 mL of the standard stock solution, and add the mobile phase to make 50 mL. To 1 mL of this solution add 1 mL of the internal standard solution, shake, and perform the test under the above conditions with 40 µL of the solution. Alprostadil, prostaglandin A₁ and the internal standard are eluted in this order, and the resolution between the peaks of alprostadil and prostaglandin A₁ is not less than 10, and that between prostaglandin A₁ and the internal standard is not less than 2.0.

System repeatability: When the test is repeated 6 times with 40 µL of the sample solution under the above conditions, the relative standard deviation of the ratio of the peak area of alprostadil to that of the internal standard is not more than 2.0%.

**Containers and storage**

Containers—Hermetic containers.

Storage—Light-resistant, not exceeding 5°C, avoiding freezing.

Optical rotation $<2.49^\circ$ [α]$^D_{20}$; +126 - +138° (0.1 g calculated on the anhydrous basis, dilute ethanol, 20 mL, 100 mm).

pH $<2.54^\circ$ Dissolve 0.10 g of Alprostadil Alfadex in 20 mL of water: the pH of this solution is between 4.0 and 5.0.

Purity (1) Clarity and color of solution—Dissolve 1.0 g of Alprostadil Alfadex in 10 mL of water: the solution is colorless. Perform the test with this solution as directed under Ultraviolet-visible Spectrophotometry within 30 minutes after preparation of the solution: the absorbance at 450 nm is not larger than 0.10.

(2) Prostaglandin $A_1$—Dissolve 0.10 g of Alprostadil Alfadex in 5 mL of water, add exactly 5 mL of the internal standard solution and ethanol (95) to make 15 mL, and use this solution as the sample solution. Separately, dissolve 1.5 mg of prostaglandin $A_1$ in ethanol (95) to make exactly 100 mL. Pipet 3 mL of this solution, add exactly 5 mL of the internal standard solution, 2 mL of ethanol (95) and water to make 15 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography $<2.01^\circ$ according to the operating conditions described in the Assay, and calculate the ratios, $Q_7$ and $Q_8$, of the peak area of prostaglandin $A_1$ to that of the internal standard: $Q_7$ is not larger than $Q_8$.

Internal standard solution—A solution of propyl parahydroxybenzoate in dilute ethanol (1 in 15,000).

(3) Related substances—Dissolve 0.10 g of Alprostadil Alfadex in 3 mL of water, add exactly 3 mL of ethyl acetate, shake, centrifuge, and use the supernatant liquid obtained as the sample solution. Separately, weigh accurately about 0.1 g of Alprostadil RS, dissolve in 5 mL of ethanol (95) (3 in 200,000) and 5 mL of the internal standard solution. Proceed with 10 μL of this solution under the above operating conditions, and calculate the resolution. Use a column giving elution of alprostadil, the internal standard and prostaglandin $A_1$ in this order and complete separation of these peaks.

Containers and storage Containers—Tight containers.

Storage—Light-resistant, at a temperature not exceeding 5°C.

Expiration date 24 months after preparation.

Dried Aluminum Hydroxide Gel

Dried Aluminum Hydroxide Gel contains not less than 50.0% of aluminum oxide ($\text{Al}_2\text{O}_3$: 101.96).

Description Dried Aluminum Hydroxide Gel occurs as a white, amorphous powder. It is odorless and tasteless.

Most of it dissolves in dilute hydrochloric acid and in sodium hydroxide TS.

Identification To 0.2 g of Dried Aluminum Hydroxide Gel add 20 mL of dilute hydrochloric acid, warm, and centrifuge: the supernatant liquid responds to the Qualitative Tests $<1.09^\circ$ for aluminum salt.

Purity (1) Acidity or alkalinity—To 1.0 g of Dried Aluminum Hydroxide Gel add 25 mL of water, shake well, and centrifuge: the supernatant liquid is neutral.

(2) Chloride $<1.03^\circ$—To 1.0 g of Dried Aluminum Hydroxide Gel add 30 mL of dilute nitric acid, heat gently to boil while shaking, cool, add water to make 100 mL, and centrifuge. To 5 mL of the supernatant liquid add 6 mL of dilute nitric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 0.40 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.284%).

(3) Sulfate $<1.14^\circ$—To 1.0 g of Dried Aluminum Hydroxide Gel add 15 mL of dilute hydrochloric acid, heat

$$M_5: \text{Amount (mg) of Alprostadil}$$

Internal standard solution—A solution of propyl parahydroxybenzoate in dilute ethanol (1 in 15,000).

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 205 nm).

Column: A stainless steel column about 5 mm in inside diameter and about 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: A mixture of 0.02 mol/L potassium dihydrogenphosphate and acetonitrile (3:2).

Flow rate: Adjust the flow rate so that the retention time of alprostadil is about 6 minutes.

Selection of column: Dissolve about 0.1 g of Alprostadil Alfadex in 5 mL of water, add 5 mL of a solution of prostaglandin $A_1$ in ethanol (95) (3 in 200,000) and 5 mL of the internal standard solution. Proceed with 10 μL of this solution under the above operating conditions, and calculate the resolution. Use a column giving elution of alprostadil, the internal standard and prostaglandin $A_1$ in this order and complete separation of these peaks.

Related substances—Dissolve 0.10 g of Alprostadil Alfadex in 20 mL of water, add exactly 5 mL of the internal standard solution and ethanol (95) to make 15 mL, and use this solution as the sample solution. Separately, dissolve 1.5 mg of prostaglandin $A_1$ in ethanol (95) to make exactly 100 mL. Pipet 3 mL of this solution, add exactly 5 mL of the internal standard solution, 2 mL of ethanol (95) and water to make 15 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography $<2.01^\circ$ according to the operating conditions described in the Assay, and calculate the ratios, $Q_7$ and $Q_8$, of the peak area of prostaglandin $A_1$ to that of the internal standard: $Q_7$ is not larger than $Q_8$.

Internal standard solution—A solution of propyl parahydroxybenzoate in dilute ethanol (1 in 15,000).

(3) Related substances—Dissolve 0.10 g of Alprostadil Alfadex in 3 mL of water, add exactly 3 mL of ethyl acetate, shake, centrifuge, and use the supernatant liquid obtained as the sample solution. Separately, dissolve 1.0 mg of prostaglandin $A_1$ in ethyl acetate to make exactly 100 mL. Pipet 3 mL of this solution, add exactly 5 mL of the internal standard solution, 2 mL of ethyl acetate to make exactly 100 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Thin-layer Chromatography $<2.03^\circ$. Spot 10 μL of each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of ethyl acetate, hexane and acetic acid (100) (10:2:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly a solution of phosphomolybdic acid in ethanol (95) (1 in 4) on the plate, and heat at 100°C for 5 minutes: the spots other than the principal spot from the sample solution, and the spots other than the spot corresponding to the spot from the standard solution are all not more intense than the spot from the standard solution.

Water $<2.48^\circ$ Not more than 6.0% (0.2 g, direct titration).

Assay Weigh accurately about 0.1 g of Alprostadil Alfadex, dissolve in 5 mL of water, add exactly 5 mL of the internal standard solution and water to make 15 mL, and use this solution as the sample solution. Separately, weigh accurately about 3 mg of Alprostadil RS, dissolve in 5 mL of ethanol (95), add exactly 5 mL of the internal standard solution and water to make 15 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography $<2.01^\circ$ according to the following conditions, and calculate the ratios, $Q_7$ and $Q_8$, of the peak area of alprostadil to that of the internal standard.

Amount (mg) of alprostadil (C$_7$H$_8$O$_4$) = $M_5 \times Q_7 / Q_8$
Dried Aluminum Hydroxide Gel Fine Granules

乾燥水酸化アルミニウムゲル細粒

Dried Aluminum Hydroxide Gel Fine Granules contain not less than 47.0% of aluminum oxide (Al₂O₃: 101.96).

**Method of preparation** Prepare as directed under Granules, with Dried Aluminum Hydroxide Gel.

**Identification** To 0.2 g of Dried Aluminum Hydroxide Gel Fine Granules add 20 mL of dilute hydrochloric acid, warm and centrifuge: the supernatant liquid responds to the Qualitative Tests <1.09> for aluminum salt.

**Acid-consuming capacity** Proceed as directed for Acid-consuming capacity under Dried Aluminum Hydroxide Gel: the volume of 0.1 mol/L hydrochloric acid VS consumed is not less than 235 mL per g of Dried Aluminum Hydroxide Gel Fine Granules.

**Assay** Proceed as directed in the Assay under Dried Aluminum Hydroxide Gel.

Each mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS = 2.549 mg of Al₂O₃

**Containers and storage** Containers—Tight containers.

Natural Aluminum Silicate

天然ケイ酸アルミニウム

**Description** Natural Aluminum Silicate occurs as a white or slightly colored powder. It is odorless and tasteless. It is practically insoluble in water, in ethanol (95) and in diethyl ether.

Natural Aluminum Silicate (1 g) dissolves when heated in 20 mL of a solution of sodium hydroxide (1 in 5), with some decomposition, leaving a large amount of insoluble substance.

**Identification** (1) To 0.5 g of Natural Aluminum Silicate add 3 mL of diluted sulfuric acid (1 in 3), heat until white fumes evolve, cool, add 20 mL of water, and filter. Render the filtrate slightly acid with ammonia TS: the solution responds to the Qualitative Tests <1.09> for aluminum salt.

(2) Prepare a bead by fusing ammonium sodium hydrogenphosphate tetrahydrate on a platinum loop. Place the bead in contact with Natural Aluminum Silicate, and fuse again: an infusible material appears in the bead, producing, upon cooling, an opaque bead with a web-like structure.

**Purity** (1) Acidity or alkalinity—Shake 5.0 g of Natural Aluminum Silicate with 100 mL of water, and centrifuge: the supernatant liquid so obtained is neutral.
Chloride—To 5.0 g of Natural Aluminum Silicate add 100 mL of water, boil gently for 15 minutes while shaking, then cool, add water to restore the original volume, and centrifuge. To 10 mL of the supernatant liquid add 6 mL of dilute hydrochloric acid, dilute to 50 mL with water, and perform the test using this solution as the test solution. Prepare the control solution with 0.30 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.021%).

Sulfate—To the residue obtained in (6) add 3 mL of dilute hydrochloric acid, heat on a water bath for 10 minutes, dilute to 50 mL with water, and filter. To 2.0 mL of the filtrate add 1 mL of dilute hydrochloric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 1.0 mL of 0.005 mol/L sulfuric acid VS (not more than 0.480%).

Heavy metals—To 1.5 g of Natural Aluminum Silicate add 50 mL of water and 5 mL of hydrochloric acid, boil gently for 20 minutes while shaking, then cool, centrifuge, remove the supernatant liquid, wash the residue with two 10-mL portions of water, centrifuging each time, combine these washings with the filtrate, and add ammonia solution (28) dropwise, until a precipitate just appears. Add dropwise dilute hydrochloric acid with vigorous shaking and redissolve the precipitate. Heat the mixture with 0.45 g of hydroxylammonium chloride, cool, and add 0.45 g of sodium acetate trihydrate, 6 mL of dilute acetic acid and water to make 150 mL. Perform the test, using 50 mL of this solution as the test solution. Prepare the control solution with 2.0 mL of Standard Lead Solution, 0.15 g of hydroxylammonium chloride, 0.15 g of sodium acetate trihydrate, 2 mL of dilute acetic acid and water to make 50 mL (not more than 40 ppm).

Arsenic—To 1.0 g of Natural Aluminum Silicate, add 5 mL of dilute hydrochloric acid, heat gently to boil while shaking well, cool rapidly, and centrifuge. Mix the residue with 5 mL of dilute hydrochloric acid with shaking, centrifuge, then add 10 mL of water to the residue, and repeat the extraction in the same manner. Concentrate the combined extracts on a water bath to 5 mL. Use this solution as the test solution, and perform the test (not more than 2 ppm).

Soluble salts—Evaporate 50 mL of the supernatant liquid obtained in (1) on a water bath to dryness, and ignite the residue at 700°C for 2 hours: the mass of the ignited residue is not more than 40 mg.

Fluoride—(i) Apparatus: Use a hard glass apparatus as illustrated in the figure. Ground-glass joints may be used.

(ii) Procedure: Transfer 5.0 g of Natural Aluminum Silicate to the distilling flask A with the aid of 20 mL of water, add about 1 g of glass wool and 50 mL of diluted purified sulfuric acid (1 in 2), and connect A to the distillation apparatus, previously washed with steam and then connected to the steam generator B vigorously, and introduce the generated steam into F. Simultaneously, heat A gradually until the temperature of the solution in A reaches 130°C, then open the rubber tube F, close the rubber tube G, boil water in the steam generator B vigorously, and introduce the generated steam into F. Simultaneously, heat A, and maintain the temperature of the solution in A between 135°C and 145°C. Adjust the distilling rate to about 10 mL per minute. Collect about 170 mL of the distillate, then stop the distillation, wash C with a small quantity of water, combine the washings with the distillate, add water to make exactly 200 mL, and use this solution as the test solution. Perform the test with the test solution as directed in the procedure of determination for fluoride under Oxygen Flask Combustion Method 1.06. No corrective solution is used in this procedure. The content of fluoride (F) is not more than 0.01%.

Amount (mg) of fluoride (F: 19.00) in the test solution

\[
\text{Amount (mg) of fluoride in 5 mL of the standard solution} = \frac{V_1}{V_2} \times \frac{A_{f}}{A_{S}} \times \frac{200}{V}
\]

Loss on drying Not more than 20.0% (1 g, 105°C, 3 hours).

Adsorptive power To 0.10 g of Natural Aluminum Silicate add 20 mL of a solution of methylene blue trihydrate (3 in 2000), shake for 15 minutes, allow to stand for 5 hours at 37 ± 2°C, and centrifuge. Dilute 1.0 mL of the supernatant liquid with water to 200 mL. Place 50 mL of the solution in a Nessler tube and observe horizontally or vertically against a white background: the color of the solution is not deeper than that of the following control solution.

Control solution: Dilute 1.0 mL of a solution of methylene blue trihydrate (3 in 2000) with water to 400 mL, and use 50 mL of this solution.

Containers and storage Containers—Well-closed containers.
Synthetic Aluminum Silicate

**Description**  Synthetic Aluminum Silicate occurs as a white powder. It is odorless and tasteless.

It is practically insoluble in water, in ethanol (95) and in diethyl ether.

Synthetic Aluminum Silicate (1 g) dissolves when heated in 20 mL of a solution of sodium hydroxide (1 in 5), leaving a small amount of insoluble substance.

**Identification** (1) To 0.5 g of Synthetic Aluminum Silicate add 3 mL of diluted sulfuric acid (1 in 3), heat until white fumes evolve, cool, add 20 mL of water, and filter. Render the filtrate slightly acid with ammonia TS: the solution responds to the Qualitative Tests for aluminum salt.

(2) Prepare a bead by fusing ammonium sodium hydrogenphosphate tetrahydrate on a platinum loop. Place the bead in contact with Synthetic Aluminum Silicate, and fuse again: an infusible material appears in the bead, producing, upon cooling, an opaque bead with a web-like structure.

**Purity** (1) Acidity or alkalinity—Shake 1.0 g of Synthetic Aluminum Silicate with 20 mL of water, and centrifuge: the supernatant liquid so obtained is neutral.

(2) Chloride  To 5.0 g of Synthetic Aluminum Silicate add 100 mL of water, boil gently for 15 minutes while shaking, then cool, add water to restore the original volume, and centrifuge. To 10 mL of the supernatant liquid add 6 mL of dilute nitric acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 0.30 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.021%).

(3) Sulfate  To 2.0 mL of the supernatant liquid obtained in (2) add 1 mL of dilute hydrochloric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution with 1.0 mL of 0.005 mol/L sulfuric acid VS (not more than 0.480%).

(4) Heavy metals  To 3.0 g of Synthetic Aluminum Silicate add 50 mL of water and 5 mL of hydrochloric acid, boil gently for 20 minutes while shaking, then after cooling, centrifuge, remove the supernatant liquid, wash the precipitate with two 10-mL portions of water, centrifuging each time, combine these washings with the filtrate, and add ammonia solution (28) dropwise until a precipitate just appears. Add dropwise dilute hydrochloric acid with vigorous shaking to redissolve the precipitate. Heat the solution with 0.45 g of hydroxylammonium chloride, and after cooling, add 0.45 g of sodium acetate trihydrate, 6 mL of dilute acetic acid and water to make 150 mL. Perform the test with 50 mL of this solution as the test solution. Prepare the control solution with 3.0 mL of Standard Lead Solution, 0.15 g of hydroxylammonium chloride, 0.15 g of sodium acetate trihydrate, 2 mL of dilute acetic acid and water to make 50 mL (not more than 30 ppm).

(5) Arsenic  To 1.0 g of Synthetic Aluminum Silicate add 10 mL of dilute hydrochloric acid, heat gently to boiling while shaking well, cool rapidly, and centrifuge. Mix the residue with 5 mL of dilute hydrochloric acid with shaking, centrifuge, then add 10 mL of water to the residue, and repeat the extraction in the same manner. Concentrate the combined extracts on a water bath to 5 mL. Use this solution as the test solution, and perform the test (not more than 2 ppm).

**Loss on drying**  Not more than 20.0% (1 g, 105°C, 3 hours).

**Acid-consuming capacity**  Weigh accurately about 1 g of Synthetic Aluminum Silicate, transfer to a glass-stoppered flask, add 200 mL of 0.1 mol/L hydrochloric acid VS, exactly measured, stopper the flask, and shake at 37 ± 2°C for 1 hour. Filter, pipet 50 mL of the filtrate, and titrate by stirring well the excess hydrochloric acid with 0.1 mol/L sodium hydroxide VS until the pH of the solution changes to 3.5. The volume of 0.1 mol/L hydrochloric acid VS consumed is not less than 50.0 mL per g of Synthetic Aluminum Silicate.

**Containers and storage**  Containers—Well-closed containers.

Aluminum Monostearate

モノステアリン酸アルミニウム

Aluminum Monostearate is mainly aluminum compounds of stearic acid (C_{18}H_{36}O_{2}: 284.48) and palmitic acid (C_{16}H_{32}O_{2}: 256.42).

Aluminum Monostearate, when dried, contains not less than 7.2% and not more than 8.9% of aluminum (AI: 26.98).

**Description**  Aluminum Monostearate occurs as a white to yellowish white powder. It is odorless or has a faint, characteristic odor.

It is practically insoluble in water, in ethanol (95) and in diethyl ether.

**Identification** (1) Heat 3 g of Aluminum Monostearate with 30 mL of hydrochloric acid in a water bath with occasional shaking for 10 minutes. After cooling, shake the mixture vigorously with 50 mL of water and 30 mL of diethyl ether for 3 minutes, and allow to stand. To the separated aqueous layer add sodium hydroxide TS until the solution becomes slightly turbid, and filter: the filtrate responds to the Qualitative Tests for aluminum salt.

(2) Wash the diethyl ether layer separated in (1) with two 20-mL portions of water, and evaporate the diethyl ether layer on a water bath: the residue melts at above 54°C.

**Acid value for fatty acid**  Weigh accurately about 1 g of fatty acid obtained in the Identification (2), transfer a 250-mL glass-stoppered flask, add 100 mL of a mixture of diethyl ether and ethanol (95) (2:1), warm to dissolve, add several drops of phenolphthalein TS, and proceed as directed under Acid Value.

**Purity** (1) Free fatty acid—Mix 1.0 g of Aluminum Monostearate with about 50 mL of a mixture of neutralized ethanol and diethyl ether
(1:1), combine the filtrate and the washings, and add 2.1 mL of 0.1 mol/L potassium hydroxide VS: a red color develops.

(2) Water-soluble salts—Heat 2.0 g of Aluminum Monostearate with 80 mL of water in a loosely stoppered conical flask on a water bath for 30 minutes with occasional shaking. After cooling, filter through dry filter paper, wash the residue with a small amount of water, combine the washings with the filtrate, add water to make 100 mL, evaporate 50 mL of this solution on a water bath, and heat strongly at 600°C: the mass of the residue is not more than 10.0 mg.

(3) Heavy metals <1.07>—Heat 1.0 g of Aluminum Monostearate over a small flame with caution at the beginning, and continue the heating, gradually raising the temperature, to ash. After cooling, add 10 mL of diluted hydrochloric acid (1 in 2), evaporate on a water bath, and boil the residue with 20 mL of water for 1 minute. Cool, filter, wash the residue with water, combine the filtrate and the washings, and add 2 mL of dilute acetic acid and water to make 50 mL. Perform the test using this solution as the test solution. Evaporate 10 mL of diluted hydrochloric acid (1 in 2) on a water bath to dryness, add 2 mL of dilute acetic acid and 50 mL of Standard Lead Solution, dilute with water to make 50 mL, and use this solution as the control solution (not more than 50 ppm).

(4) Arsenic <1.11>—Mix 1.0 g of Aluminum Monostearate with 2 g of magnesium nitrate hexahydrate, ignite over a small flame, moisten the residue after cooling, and ignite gently to ash, and continue the heating, gradually raising the temperature, to ash. After cooling, add 2.4 mL of water to make 10 mL, evaporate on a water bath, and boil the residue with 0.5 mL of nitric acid, and heat to light red. Perform a blank determination.

Loss on drying <2.41> Not more than 3.0% (1 g, 105°C, 3 hours).

Assay Weigh accurately about 1 g of Aluminum Monostearate, previously dried, ignite gently to ash, and cool. Add dropwise 0.5 mL of nitric acid, evaporate on a water bath by heating, and then heat strongly between 900°C and 1100°C to a constant mass. After cooling, weigh rapidly the ignited residue, and designate the mass as aluminum oxide (Al₂O₃): 101.96.

Amount (mg) of aluminum (Al)

\[ \text{Amount (mg) of aluminum (Al)} = \text{amount (mg) of aluminum oxide (Al}_2\text{O}_3) \times 0.529 \]

Containers and storage Containers—Well-closed containers.

Aluminum Potassium Sulfate Hydrate

Alum

硫酸アルミニウムカリウム水和物

AlK(SO₄)₂·12H₂O: 474.39

Aluminum Potassium Sulfate Hydrate contains not less than 99.5% of AlK(SO₄)₂·12H₂O.

Description Aluminum Potassium Sulfate Hydrate occurs as colorless or white crystals or powder. It is odorless. It has a slightly sweet, strongly astringent taste.

It is freely soluble in water, and practically insoluble in ethanol (95) and in diethyl ether.

A solution of Aluminum Potassium Sulfate Hydrate (1 in 20) is acid.

Identification A solution of Aluminum Potassium Sulfate Hydrate (1 in 10) responds to the Qualitative Tests <1.09> for aluminum salt, to the Qualitative Tests <1.09> (1), (3) and (4) for potassium salt, and to the Qualitative Tests <1.09> (1) and (3) for sulfite.

Purity (1) Heavy metals <1.07>—Proceed with 1.0 g of Aluminum Potassium Sulfate Hydrate according to Method 1, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(2) Iron <1.10>—Prepare the test solution with 1.0 g of Aluminum Potassium Sulfate Hydrate according to Method 1, and perform the test according to Method A. Prepare the control solution with 2.0 mL of Standard Iron Solution (not more than 20 ppm).

(3) Arsenic <1.11>—Prepare the test solution with 0.6 g of Aluminum Potassium Sulfate Hydrate, according to Method 1, and perform the test (not more than 3.3 ppm).

Assay Weigh accurately about 4.5 g of Aluminum Potassium Sulfate Hydrate, and dissolve in water to make exactly 200 mL. Take exactly 20 mL of this solution, and add exactly 30 mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS and 20 mL of acetic acid-ammonium acetate buffer solution, pH 4.8, boil for 5 minutes, and cool. Add 55 mL of ethanol (95), and titrate <2.50> with 0.05 mol/L zinc acetate VS (indicator: 2 mL of dithizone TS), until the color of the solution changes from light dark green to light red. Perform a blank determination.

Each mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS

\[ = 23.72 \text{ mg of AlK(SO}_4)_2·12\text{H}_2\text{O} \]

Containers and storage Containers—Tight containers.

Dried Aluminum Potassium Sulfate

Burnt Alum

乾燥硫酸アルミニウムカリウム

AlK(SO₄)₂: 258.21

Dried Aluminum Potassium Sulfate, when dried, contains not less than 98.0% of AlK(SO₄)₂.

Description Dried Aluminum Potassium Sulfate occurs as white masses or white powder. It is odorless. It has a slightly sweet, astringent taste.

It is freely soluble in hot water and practically insoluble in ethanol (95).

It dissolves slowly in water.

Identification A solution of Dried Aluminum Potassium Sulfate (1 in 20) responds to the Qualitative Tests <1.09> for aluminum salt, to the Qualitative Tests <1.09> (1), (3) and (4) for potassium salt, and to the Qualitative Tests <1.09> (1) and (3) for sulfite.
Purity  (1) Water-insoluble substances—To 2.0 g of Dried Aluminum Potassium Sulfate add 40 mL of water, shake frequently, and allow to stand for 48 hours. Collect the insoluble residue on a glass filter (G4), wash with 50 mL of water, and dry at 105°C for 2 hours: the mass of the residue is not more than 50 mg.

(2) Heavy metals 《1.07》—Dissolve 0.5 g of Dried Aluminum Potassium Sulfate in 45 mL of water, and filter, if necessary. Add 2 mL of dilute acetic acid and water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 2.0 mL of Standard Lead Solution, 2 mL of dilute acetic acid and water to make 50 mL (not more than 40 ppm).

(3) Iron 《1.1D》—Prepare the test solution with 0.54 g of Dried Aluminum Potassium Sulfate according to Method 1, and perform the test according to Method A. Prepare the control solution with 2.0 mL of Standard Iron Solution (not more than 37 ppm).

(4) Arsenic 《1.1D》—Prepare the test solution with 0.40 g of Dried Aluminum Potassium Sulfate, according to Method 1, and perform the test (not more than 5 ppm).

Loss on drying 《2.41》 Not more than 15.0% (2 g, 200°C, 4 hours).

Assay Weigh accurately about 1.2 g of Dried Aluminum Potassium Sulfate, previously dried, add 80 mL of water, and heat on a water bath with occasional shaking for 20 minutes. Cool, add water to make exactly 100 mL, and filter, if necessary. Discard the first 30 mL of the filtrate, take exactly the subsequent 20 mL of the filtrate, and add exactly 30 mL of 0.05 mol/L disodium dihydrogen ethylenediamine tetraacetate VS and 20 mL of acetic acid-ammonium chloride TS and 1 mL of ammonia TS: a white, gelatinous precipitate is produced, which changes to red upon the addition of 5 drops of alizarin red S TS (aluminum sulfate).

Place 100 mL of Alum Solution in an evaporating dish, evaporate on a water bath to dryness, and dissolve the residue in 5 mL of water: the solution responds to the Qualitative Tests 《1.09》 for potassium salt.

(3) Alum Solution responds to the Qualitative Tests 《1.09》 (1) and (2) for sulfate.

Assay Pipet 50 mL of Alum Solution, add exactly 30 mL of 0.02 mol/L disodium dihydrogen ethylenediamine tetraacetate VS, and further add 20 mL of acetic acid-ammonium acetate buffer solution, pH 4.8. Boil for 5 minutes, cool, add 55 mL of ethanol (95), and titrate 《2.50》 with 0.02 mol/L zinc acetate VS (indicator: 2 mL of dithizone TS), until the color of the solution changes from light dark green to light red. Perform a blank determination.

Each mL of 0.02 mol/L disodium dihydrogen ethylenediamine tetraacetate VS

= 9.488 mg of AlK(SO4)2.12H2O

Containers and storage Containers—Tight containers.

**Alum Solution**

ミョウバン水

Alum Solution contains not less than 0.27 w/v% and not more than 0.33 w/v% of aluminum potassium sulfate Hydrate [AlK(SO4)2.12H2O: 474.39].

Method of preparation

| Aluminum Potassium Sulfate Hydrate  | 3 g |
| Mentha Water                      | 50 mL |
| Water, Purified Water or Purified | a sufficient quantity |

To make 1000 mL

Dissolve and mix the above ingredients.

Description Alum Solution is a clear, colorless liquid. It has the odor of the mentha oil and an astringent taste.

**Amantadine Hydrochloride**

Amantadine Hydrochloride, when dried, contains not less than 99.0% of C10H17N.HCl.

Description Amantadine Hydrochloride occurs as a white, crystalline powder. It is odorless, and has a bitter taste.

It is very soluble in formic acid, freely soluble in water, in methanol and in ethanol (95), and practically insoluble in diethyl ether.

Identification (1) To 0.1 g of Amantadine Hydrochloride add 1 mL of pyridine and 0.1 mL of acetic anhydride, dissolve by boiling for 1 hour, add 10 mL of dilute hydrochloric acid, and cool in ice water. Filter the crystals separated, wash with water, and dry at 105°C for 1 hour: the residue melts 《2.6D》 between 147°C and 151°C.

(2) Determine the infrared absorption spectrum of Amantadine Hydrochloride, previously dried, as directed in the potassium chloride disk method under Infrared Spectrophotometry 《2.2S》, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) A solution of Amantadine Hydrochloride (1 in 50) responds to the Qualitative Tests 《1.09》 for chloride.

pH 《2.54》 Dissolve 1.0 g of Amantadine Hydrochloride in
JP XVI

Official Monographs / Ambenonium Chloride 359

5 mL of water: the pH of this solution is between 4.0 and 6.0.

**Purity (1)** Clarity and color of solution—Dissolve 1.0 g of Amantadine Hydrochloride in 10 mL of water: the solution is clear and colorless.

**Heavy metals <1.07**—Proceed with 2.0 g of Amantadine Hydrochloride according to Method 4, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

**Arsenic <1.17**—Prepare the test solution with 1.0 g of Amantadine Hydrochloride according to Method 3, and perform the test (not more than 2 ppm).

**Related substances**—Dissolve 0.50 g of Amantadine Hydrochloride in 10 mL of water, add 10 mL of sodium hydroxide TS and 10 mL of chloroform, and shake. Filter the chloroform layer through absorbent cotton with 3 g of anhydrous sodium sulfate on a funnel, and use the filtrate as the sample solution. Pipet 1 mL of the sample solution, add chloroform to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 2 μL of the sample solution and standard solution as directed under Gas Chromatography <2.02> according to the following conditions. Determine each peak area of these solutions by the automatic integration method: each peak area other than that of amantadine from the sample solution is not larger than 1/3 times the peak area of amantadine from the standard solution, and the total area of each peak is not larger than the peak area of amantadine from the standard solution.

**Operating conditions**—

- Detector: A hydrogen flame-ionization detector.
- Column: A glass column about 3 mm in inside diameter and about 2 m in length, packed with siliceous earth for gas chromatography (150 to 180 μm in particle diameter) coated with a mixture (L) of branched hydrocarbon of petroleum hexamethyldodecanese group for gas chromatography and potassium hydroxide at the ratios of 2% and 1%, respectively.
- Column temperature: Inject at a constant temperature of about 125°C, maintain the temperature for 5 minutes, raise at the rate of 5°C per minute to 150°C, and maintain at a constant temperature of about 150°C for 15 minutes.
- Carrier gas: Nitrogen
- Flow rate: Adjust the flow rate so that the retention time of amantadine is about 11 minutes.
- Selection of column: Dissolve 0.15 g of naphthalene in 5 mL of the sample solution, and add chloroform to make 100 mL. Proceed with 2 μL of this solution under the above operating conditions, and calculate the resolution. Use a column giving elution of naphthalene and amantadine in this order with the resolution between these peaks being not less than 2.5.
- Detection sensitivity: Adjust the detection sensitivity so that the peak height of amantadine obtained from 2 μL of the standard solution composes about 10% of the full scale.
- Time span of measurement: About twice as long as the retention time of amantadine beginning after the solvent peak.

**Loss on drying <2.41** Not more than 0.5% (1 g, 105°C, 3 hours).

**Residue on ignition <2.44** Not more than 0.2% (1 g).

**Assay** Weigh accurately about 0.2 g of Amantadine Hydrochloride, previously dried, dissolve in 2 mL of formic acid, add exactly 15 mL of 0.1 mol/L perchloric acid VS, and heat on a water bath for 30 minutes. After cooling, add acetic acid (100) to make 70 mL, and titrate <2.50> the excess perchloric acid with 0.1 mol/L sodium acetate VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 18.77 mg of C₃H₇N.HCl

**Containers and storage** Containers—Well-closed containers.

**Ambenonium Chloride**

アンペノニウム塩化物

![Chemical structure of Ambenonium Chloride](image)

C₂₈H₃₇Cl₃N₄O₂: 608.47

2,2’-[(1,2-Dioxoethane-1,2-diyl)diimino]bis[N-(2-chlorobenzyl)-N,N-diethylethylamaminium] dichloride [115-79-7]

Ambenonium Chloride contains not less than 98.5% of C₂₈H₃₇Cl₃N₄O₂, calculated on the dried basis.

**Description** Ambenonium Chloride occurs as a white powder.
- It is freely soluble in water, in methanol and in acetic acid (100), soluble in ethanol (95), and slightly soluble in acetic anhydride.
- It is hygroscopic.
- Melting point: about 205°C (with decomposition).

**Identification (1)** Determine the absorption spectrum of a solution of Ambenonium Chloride in methanol (1 in 5000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Ambenonium Chloride, previously dried, as directed in the potassium chloride disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) A solution of Ambenonium Chloride (1 in 100) responds to the Qualitative Tests <1.09> for chloride.

**Purity (1)** Clarity and color of solution—Dissolve 1.0 g of Ambenonium Chloride in 10 mL of water: the solution is clear and colorless.

**Heavy metals <1.07**—Proceed with 1.0 g of Ambenonium Chloride according to Method 4, and perform the test. Use a solution of magnesium nitrate in ethanol (95) (1 in 5). Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

**Related substances**—Dissolve 0.10 g of Ambenonium
Amidotrizoic Acid

アミドトリゾ酸

C₁₁H₉I₃N₂O₄: 613.91
3,5-Bis(acetylamino)-2,4,6-triiodobenzoic acid
[117-96-4]

Amidotrizoic Acid, calculated on the dried basis, contains not less than 98.0% of C₁₁H₉I₃N₂O₄.

Description Amidotrizoic Acid occurs as a white, crystalline powder. It is odorless.

It is slightly soluble in ethanol (95), very slightly soluble in water, and practically insoluble in diethyl ether.

It dissolves in sodium hydroxide TS.

Identification (1) Heat 0.1 g of Amidotrizoic Acid over a flame: a purple gas is evolved.

(2) Determine the infrared absorption spectrum of Amidotrizoic Acid as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

Purity (1) Clarity and color of solution—Dissolve 1.0 g of Amidotrizoic Acid in 10 mL of 0.2 mol/L sodium hydroxide TS: the solution is clear and colorless.

(2) Primary aromatic amines—Dissolve 0.20 g of Amidotrizoic Acid in 5 mL of water and 1 mL of sodium hydroxide TS, add 4 mL of a solution of sodium nitrite (1 in 100) and 10 mL of 1 mol/L hydrochloric acid TS, shake, and allow to stand for 2 minutes. Add 5 mL of ammonium amidosulfate TS, shake well, allow to stand for 1 minute, and add 0.4 mL of a solution of 1-naphthol in ethanol (95) (1 in 10), 15 mL of sodium hydroxide TS and water to make exactly 50 mL. Determine the absorbance of this solution at 485 nm as directed under Ultraviolet-visible Spectrophotometry <2.24> using a solution, prepared in the same manner, as the blank: the absorbance is not more than 0.15.

(3) Soluble halides—Dissolve 2.5 g of Amidotrizoic Acid in 20 mL of water and 2.5 mL of ammonia TS, add 20 mL of dilute nitric acid and water to make 100 mL, allow to stand for 15 minutes with occasional shaking, and filter. Discard the first 10 mL of the filtrate, transfer the subsequent 25 mL of the filtrate to a Nessler tube, and add ethanol (95) to make 50 mL. Proceed as directed under Chloride Limit Test <1.03> using this solution as the test solution. Prepare the control solution as follows: to 0.10 mL of 0.01 mol/L hydrochloric acid VS, add 6 mL of dilute nitric acid and water to make 25 mL, then ethanol (95) to make 50 mL.

(4) Iodine—Dissolve 0.20 g of Amidotrizoic Acid in 2.0 mL of sodium hydroxide TS, add 2.5 mL of 0.5 mol/L sulfuric acid TS, allow to stand for 10 minutes with occasional shaking, add 5 mL of chloroform, shake well, and allow to stand: the solution is colorless in the chloroform layer.

(5) Heavy metals <1.07>—Proceed with 2.0 g of Amidotrizoic Acid according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(6) Arsenic <1.17>—Prepare the test solution with 0.6 g of Amidotrizoic Acid according to Method 3, and perform the test (not more than 3.3 ppm).

Loss on drying <2.41> Not more than 7.0% (1 g, 105°C, 4 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Weigh accurately about 0.3 g of Ambenonium Chloride, and dissolve in 50 mL of a mixture of acetic anhydride and acetic acid (100) (7:3). Titrate <2.50> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 30.42 mg of C₂₈H₄₂Cl₄N₄O₂

Containers and storage Containers—Tight containers.
**Amikacin Sulfate**

アミカシン硫酸塩

C₂₂H₄₃N₅O₁₃·2H₂SO₄: 781.76
3-Amino-3-deoxy-α-D-glucoopyranosyl-(1→6)-
[6-amino-6-deoxy-α-D-glucoopyranosyl-(1→4)]-1-N-
[(25)-4-amino-2-hydroxybutanoyl]-2-deoxy-D-streptamine disulfate

Amikacin Sulfate is the sulfate of a derivative of kanamycin.

It contains not less than 691 μg (potency) and not more than 791 μg (potency) per mg, calculated on the dried basis. The potency of Amikacin Sulfate is expressed as mass (potency) of amikacin (C₂₂H₄₃N₅O₁₃·2H₂SO₄: 781.60).

Description

Amikacin Sulfate occurs as a white to yellowish white powder.

It is very soluble in water, and practically insoluble in ethanol (95).

**Identification** (1) Determine the infrared absorption spectrum of Amikacin Sulfate, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum or the spectrum of Amikacin Sulfate RS previously dried: both spectra exhibit similar intensities of absorption at the same wave numbers.

(2) Dissolve 0.1 g each of Amikacin Sulfate and Amikacin Sulfate RS in 4 mL of water, and use these solutions as the sample solution and standard solution. Perform the test with these solutions as directed under Thin-layer chromatography <2.05>. Spot 2 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of water, ammonia water (28%), methanol and tetrahydrofuran (1:1:1:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly ninhydrin-citric acid-acetic acid TS on the plate, and heat at 100°C for 10 minutes: the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

**Loss on drying** <2.47> Not more than 4.0% (1 g, in vacuum, 60°C, 3 hours).

**Assay** Weigh accurately an amount of Amikacin Sulfate and Amikacin Sulfate RS, equivalent to about 50 mg (potency), dissolve each in water to make exactly 50 mL. Pipet 200 μL each of these solutions in the test tube with glass stopper, add exactly 3 mL of pyridine and exactly 2 mL of a solution of 2,4,6-trinitrobenzenesulfonic acid (1 in 100), stopper tightly, and heat in a water bath at 70°C for 30 minutes. After cooling, add exactly 2 mL each of acetic acid (100), and use these solutions as the sample solution and standard solution, respectively. Perform the test with exactly 20 μL each of these solutions as directed under Liquid Chromatography <2.01> according to the following conditions, and determine the heights, H₁ and H₅, of the peak of amikacin derivative.

Amount [μg (potency)] of amikacin (C₂₂H₄₃N₅O₁₃) = M₅ × H₅/H₁ × 1000

M₅: Amount [mg (potency)] of Amikacin Sulfate RS

**Operating conditions**

Column: A stainless steel column 4.6 mm in inside diameter and 25 cm in length, packed with octadeclisilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 35°C.

Mobile phase: Dissolve 2.72 g of potassium dihydrogen phosphate in 800 mL of water, adjust to pH 6.5 with a solution of potassium hydroxide (1 in 40), and add water to make 1000 mL. To 280 mL of this solution add 720 mL of methanol, and mix.

Flow rate: Adjust the flow rate so that the retention time of amikacin derivative is about 9 minutes.

**System suitability**

System performance: Dissolve about 5 mg (potency) of Amikacin Sulfate and about 5 mg (potency) of Kanamycin Sulfate in 5 mL of water. Transfer 200 μL of this solution in a glass-stoppered test tube, add 3 mL of pyridine and 2 mL of a solution of 2,4,6-trinitrobenzenesulfonic acid (1 in 100),
stopper tightly, heat in a water bath at 70°C for 30 minutes. After cooling, add 2 mL of acetic acid (100). When the procedure is run with 20 μL of this solution under the above operating conditions, amikacin derivative and kanamycin derivative are eluted in this order with the resolution between these peaks being not less than 5.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratios of the peak height of amikacin derivative is not more than 2.0%.

Containers and storage Containers—Hermetic containers.

Amikacin Sulfate for Injection

Amikacin Sulfate for Injection is a preparation for injection, which is dissolved before use.

It contains not less than 90.0% and not more than 115.0% of the labeled amount of amikacin (C_{22}H_{43}N_{7}O_{15}; 585.60).

Method of preparation Prepare as directed under Injections, with Amikacin Sulfate.

Description Amikacin Sulfate for Injection occurs as white to yellowish white masses or powder.

Identification Dissolve an amount of Amikacin Sulfate for Injection, equivalent to 25 mg (potency) of Amikacin Sulfate according to the labeled amount, in 1 mL of water, and use this solution as the sample solution. Separately, dissolve 25 mg (potency) of Amikacin Sulfate RS in 1 mL of water, and use this solution as the standard solution. Then, proceed as directed in the Identification (2) under Amikacin Sulfate.

Osmotic pressure ratio Being specified separately.

pH <2.54> Dissolve an amount of Amikacin Sulfate for Injection, equivalent to 0.1 g (potency) of Amikacin Sulfate according to the labeled amount, in 10 mL of water: the pH of this solution is 6.0 to 7.5.

Purity Clarity and color of solution—Dissolve an amount of Amikacin Sulfate for Injection, equivalent to 0.5 g (potency) of Amikacin Sulfate according to the labeled amount, in 5 mL of water: the solution is clear, and the absorbance at 405 nm of the solution determined as directed under Ultraviolet-visible Spectrophotometry <2.24> is not more than 0.15.

Loss on drying <2.41> Not more than 4.0% (1 g, in vacuum, 60°C, 3 hours).

Bacterial endotoxins <4.01> Less than 0.50 EU/mg (potency).

Uniformity of dosage units <6.02> It meets the requirement of the Mass variation test.

Foreign insoluble matter <6.06> Perform the test according to Method 2: it meets the requirement.

Insoluble particulate matter <6.07> It meets the requirement.

Sterility <4.06> Perform the test according to the Membrane filtration method: it meets the requirement.

Assay Weigh accurately the mass of the content of not less than 10 Amikacin Sulfate for Injection. Weigh accurately a portion of the content, equivalent to about 50 mg (potency) of Amikacin Sulfate, dissolve in water to make exactly 50 mL. Separately, weigh accurately an amount of Amikacin Sulfate RS, equivalent to about 50 mg (potency), and dissolve in water to make exactly 50 mL. Transfer exactly 200 μL of each of these solutions to separate glass stopped tubes, then proceed as directed in the Assay under Amikacin Sulfate RS.

\[
M_S = \frac{H_1 \times H_5}{M_S}
\]

Where:
- \( M_S \): Amount [mg (potency)] of amikacin (C_{22}H_{43}N_{7}O_{15})
- \( H_1 \): Amount [mg (potency)] of Amikacin Sulfate RS
- \( H_5 \): Amount [mg (potency)] of Amikacin Sulfate RS

Containers and storage Containers—Hermetic containers.

Amikacin Sulfate Injection

Amikacin Sulfate Injection is an aqueous injection. It contains not less than 90.0% and not more than 115.0% of the labeled amount of amikacin (C_{22}H_{43}N_{7}O_{15}; 585.60).

Method of preparation Prepare as directed under Injections, with Amikacin Sulfate.

Description Amikacin Sulfate Injection occurs as a colorless or pale yellow clear liquid.

Identification To a volume of Amikacin Sulfate Injection, equivalent to 0.1 g (potency) of Amikacin Sulfate according to the labeled amount, add water to make 4 mL, and use this solution as the sample solution. Separately, dissolve 25 mg (potency) of Amikacin Sulfate RS in 1 mL of water, and use this solution as the standard solution. Then, proceed as directed in the Identification (2) under Amikacin Sulfate RS.

Osmotic pressure ratio Being specified separately.

pH <2.54> 6.0 – 7.5

Bacterial endotoxins <4.01> Less than 0.50 EU/mg (potency).

Extractable volume <6.05> It meets the requirement.

Foreign insoluble matter <6.06> Perform the test according to Method 1: it meets the requirement.

Insoluble particulate matter <6.07> It meets the requirement.

Sterility <4.06> Perform the test according to the Membrane filtration method: it meets the requirement.

Assay Take exactly a volume of Amikacin Sulfate Injection, equivalent to about 0.1 g (potency) of Amikacin Sulfate, and add water to make exactly 100 mL. Separately, weigh accurately an amount of Amikacin Sulfate RS, equivalent to about 50 mg (potency), and add water to make exactly 50 mL. Take exactly 200 μL of each of these solutions into stopped test tubes, then proceed as directed in the Assay under Amikacin Sulfate RS.
Aminophylline Hydrate

Aminophylline Hydrate occurs as white to pale yellow granules or powder. It is odorless or slightly ammonia-like odor, and has a bitter taste.

Identification (1) Dissolve 0.75 g of Aminophylline Hydrate in 30 mL of water, and use this solution as the sample solution. To 20 mL of the sample solution add 1 mL of dilute hydrochloric acid: a precipitate is gradually formed. Solution. To 20 mL of the sample solution add 1 mL of dilute hydrochloric acid: a precipitate is gradually formed.

Dissolve 0.1 g of the crystals obtained in (1) in 50 mL of water, and shake: it dissolves almost completely. Separation of crystals begins in 2 to 3 minutes, and these crystals dissolve on the addition of a small amount of ethylenediamine.

It is gradually affected by light, and gradually loses ethylenediamine in air.

Identification (1) Dissolve 0.75 g of Aminophylline Hydrate in 30 mL of water, and use this solution as the sample solution. To 20 mL of the sample solution add 1 mL of dilute hydrochloric acid: a precipitate is gradually formed. Filter the precipitate, recrystallize from water, and dry at dilute hydrochloric acid: a precipitate is gradually formed.

To 1 g of Aminophylline Hydrate add 5 mL of water, and shake: it dissolves almost completely. Separation of crystals begins in 2 to 3 minutes, and these crystals dissolve on the addition of a small amount of ethylenediamine.

It is gradually affected by light, and gradually loses ethylenediamine in air.

To 1 g of Aminophylline Hydrate add 5 mL of water, and shake: it dissolves almost completely. Separation of crystals begins in 2 to 3 minutes, and these crystals dissolve on the addition of a small amount of ethylenediamine.

Aminophylline Hydrate contains not less than 84.0% and not more than 86.0% of theophylline (C7H8N4O2: 180.16), and not less than 14.0% and not more than 15.0% of ethylenediamine (C2H8N2: 60.10), calculated on the anhydrous basis.

Aminophylline Hydrate is practically insoluble in ethanol (95) and in diethyl ether.

To 1 g of Aminophylline Hydrate in 10 mL of hot water: the solution is clear and colorless to pale yellow.

To 0.01 g of the crystals obtained in (1) add 10 drops of hydroquinone TS and 1 drop of hydrochloric acid, and evaporate on a water bath to dryness: the residue shows a yellow-red color. Invert the dish containing the residue over a vessel containing 2 to 3 drops of ammonia TS: the color changes to red-purple, which is destroyed on the addition of 2 to 3 drops of sodium hydroxide TS.

To 0.01 g of the crystals obtained in (1) add 10 drops of hydroquinone TS and 1 drop of hydrochloric acid, and evaporate on a water bath to dryness: the residue shows a yellow-red color. Invert the dish containing the residue over a vessel containing 2 to 3 drops of ammonia TS: the color changes to red-purple, which is destroyed on the addition of 2 to 3 drops of sodium hydroxide TS.

Invert the dish containing the residue over a vessel containing 2 to 3 drops of ammonia TS: the color changes to red-purple, which is destroyed on the addition of 2 to 3 drops of sodium hydroxide TS.

Residue on ignition (2) Not more than 0.1% (1 g).

Assay (1) Theophylline—Weigh accurately about 0.25 g of Aminophylline Hydrate, and dissolve in 50 mL of water and 8 mL of ammonia TS by gentle warming on a water bath. Add exactly 20 mL of 0.1 mol/L silver nitrate VS, warm on a water bath for 15 minutes, allow to stand between 5°C and 10°C for 20 minutes, collect the precipitate by suction, and wash with three 10-mL portions of water. Combine the filtrate and washings, and add dilute nitric acid to make neutral. Add 3 mL of dilute nitric acid, and titrate with 0.1 mol/L ammonium thiocyanate VS (indicator: 2 mL of ammonium iron (III) sulfate TS). Perform a blank determination.

Each mL of 0.1 mol/L silver nitrate VS is 18.02 mg of theophylline (C7H8N4O2).

(2) Ethylenediamine—Weigh accurately about 0.5 g of Aminophylline Hydrate, and dissolve in 30 mL of water, and titrate with 0.1 mol/L hydrochloric acid VS (indicator: 3 drops of bromphenol blue TS).

Each mL of 0.1 mol/L hydrochloric acid VS is 3.005 mg of ethylenediamine (C2H8N2).

Aminophylline Injection

Aminophylline Injection is an aqueous solution for injection.

It contains not less than 75.0% and not more than 86.0% of the labeled amount of theophylline (C7H8N4O2: 180.16), and not less than 13.0% and not more than 20.0% of ethylenediamine (C2H8N2: 60.10).

The concentration of Aminophylline Injection is expressed as the quantity of aminophylline dihydrate (C18H24N10O4·2H2O: 456.46).

Method of preparation Prepare as directed under Injections, with Aminophylline Hydrate. It may be prepared with Theophylline and its equivalent Ethylenediamine, instead of Aminophylline Hydrate.

It may contain not more than 60 mg of Ethylenediamine
Amiodarone Hydrochloride / Official Monographs

364

as a stabilizer for each g of Aminophylline Hydrate.

Description Aminophylline Injection is a clear and colorless liquid. It has a slightly bitter taste. It gradually changes in color by light.

pH: 8.0 – 10.0

Identification

To a volume of Aminophylline Injection, equivalent to 0.75 g of Aminophylline Hydrate according to the labeled amount, add water to make 30 mL. Proceed with this solution as directed in the Identification under Aminophylline Hydrate.

Bacterial endotoxins

Less than 0.6 EU/mg.

Extractable volume

It meets the requirement.

Foreign insoluble matter

Perform the test according to Method 1: it meets the requirement.

Insoluble particulate matter

It meets the requirement.

Sterility

Perform the test according to the Membrane filtration method: it meets the requirement.

Assay

(1) Theophylline—Pipet a volume of Aminophylline Injection, equivalent to about 39.4 mg of theophylline (C7H8N4O2) (about 50 mg of Aminophylline Hydrate), add water to make exactly 50 mL, and use this solution as the standard solution. Separate, weigh accurately about 40 mg of theophylline for assay, previously dried at 105°C for 4 hours, dissolve in water to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 5 μL each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and determine the peak areas, A1 and A5, of theophylline in each solution.

Amount (mg) of theophylline (C7H8N4O2)

= Mₛ × A₁/₁₅₈

Mₛ: Amount (mg) of theophylline for assay

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 270 nm).

Column: A stainless steel column 6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: A mixture of diluted acetic acid (100) (1 in 100) and methanol (4:1).

Flow rate: Adjust the flow rate so that the retention time of theophylline is about 5 minutes.

System suitability—

System performance: When the procedure is run with 5 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of theophylline are not less than 3000 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 5 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of theophylline is not more than 1.0%.

(2) Ethylenediamine—To an accurately measured volume of Aminophylline Injection, equivalent to about 30 mg of ethylenediamine (C2H8N2) (about 0.2 g of Aminophylline Hydrate), add water to make 30 mL, and titrate with 0.1 mol/L hydrochloric acid VS (indicator: 2 to 3 drops of bromophenol blue TS).

Each mL of 0.1 mol/L hydrochloric acid VS = 3.005 mg of ethylenediamine (C2H8N2)

Containers and storage

Containers—Hermetic containers.

Storage—Light-resistant.

Amiodarone Hydrochloride

アミオダロン塩酸塩

C₂₅H₂₉I₂NO₃·HCl: 681.77
[2-Butylbenzofuran-3-yl][4-[2-(diethylaminomethoxy)-3,5-diiodophenyl]methanone monohydrochloride [19774-82-4]

Amiodarone Hydrochloride, when dried, contains not less than 98.5% and not more than 101.0% of C₂₅H₂₉I₂NO₃·HCl.

Description

Amiodarone Hydrochloride occurs as a white to pale yellowish white crystalline powder.

It is very soluble in water at 80°C, freely soluble in dichloromethane, soluble in methanol, sparingly soluble in ethanol (95), and very slightly soluble in water.

Melting point: about 161°C (with decomposition).

Identification

(1) Determine the absorption spectrum of a solution of Amiodarone Hydrochloride in ethanol (95) (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry (2.24), and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Amiodarone Hydrochloride as directed in the potassium bromide disk method under Infrared Spectrophotometry (2.25), and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) To 0.1 g of Amiodarone Hydrochloride add 10 mL of water, dissolve by warming at 80°C, and cool; the solution responds to the Qualitative Tests (1.09) (2) for chloride.

pH < 2.5 To 1.0 g of Amiodarone Hydrochloride add 20 mL of freshly boiled and cooled water, dissolve by warming at 80°C, and cool: the pH of this solution is between 3.2 and 3.8.

Purity

(1) Clarity and color of solution—Dissolve 0.5 g of Amiodarone Hydrochloride in 10 mL of methanol: the solution is clear, and is not more colored than the following control solutions (1) and (2).

Control solution (1): To a mixture of 1.0 mL of Cobalt (II) Chloride CS, 2.4 mL of Iron (III) Chloride CS and 0.4 mL of Copper (II) Sulfate CS, add diluted hydrochloric acid
(1 in 40) to make 10.0 mL. To 2.5 mL of this solution add diluted hydrochloric acid (1 in 40) to make 20 mL.

Control solution (2): To 3.0 mL of a mixture of 0.2 mL of Cobalt (II) Chloride CS, 9.6 mL of a mixture of Copper (II) Sulfate CS and 0.2 mL of Hydrochloric acid (1 in 40) to make 100 mL.

(2) Iodine—To 1.50 g of Amiodarone Hydrochloride add 40 mL of water, dissolve by warming at 80°C, cool, add water to make exactly 50 mL, and use this solution as the sample stock solution. Pipet 15 mL of this solution, add exactly 1 mL of 0.1 mol/L hydrochloric acid TS and exactly 1 mL of a solution of potassium iodate (107 in 10,000), add water to make exactly 20 mL, and use this solution as the sample solution. Separately, pipet 15 mL of the sample stock solution, add exactly 1 mL of 0.1 mol/L hydrochloric acid TS, exactly 1 mL of a solution of potassium iodide (441 in 5,000,000) and exactly 1 mL of a solution of potassium iodate (107 in 10,000), add water to make exactly 20 mL, and use this solution as the standard solution. Separately, pipet 15 mL of the sample stock solution, add exactly 1 mL of 0.1 mol/L hydrochloric acid TS, add water to make exactly 20 mL, and use this solution as the control solution. Allow the sample solution, standard solution and control solution to stand in a dark place for 4 hours. Perform the test with the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry <2.2>, using the control solution as the blank: the absorbance of the sample solution at 420 nm is not larger than 1/2 times the absorbance of the standard solution.

(3) Heavy metals—Proceed with 1.0 g of Amiodarone Hydrochloride according to Method 4, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(4) Related substance 1—Dissolve 0.5 g of Amiodarone Hydrochloride in 5 mL of dichloromethane, and use this solution as the sample solution. Separately, dissolve 10 mg of 2-chloroethyl diethylamine hydrochloride in 50 mL of dichloromethane, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 5 μL each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of dichloromethane, methanol and formic acid (17:2:1) to a distance of about 15 cm, and air-dry the plate. Splay evenly bismuth subnitrate TS and then hydrogen peroxide TS: the spot obtained from the sample solution corresponding to the spot from the standard solution is not more intense than the spot from the standard solution.

(5) Related substance 2—Dissolve 0.125 g of Amiodarone Hydrochloride in 25 mL of a mixture of water and acetonitrile for liquid chromatography (1:1), and use this solution as the sample solution. Pipet 2 mL of the sample solution, and add a mixture of water and acetonitrile for liquid chromatography (1:1) to make exactly 50 mL. Pipet 1 mL of this solution, add a mixture of water and acetonitrile for liquid chromatography (1:1) to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.03> according to the following conditions. Determine each peak area by the automatic integration method: the area of any peak other than amiodarone obtained from the sample solution is not larger than the peak area of amiodarone from the standard solution, and the total area of the peaks other than the peak of amiodarone is not larger than 2.5 times the peak area of amiodarone from the standard solution.

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 240 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 30°C.

Mobile phase: To 800 mL of water add 3.0 mL of acetic acid (100), adjust the pH to 4.95 with ammonium solution (28), and add water to make 1000 mL. To 300 mL of this solution add 400 mL of acetonitrile for liquid chromatography and 300 mL of methanol for liquid chromatography. Flow rate: Adjust the flow rate so that the retention time of amiodarone is about 24 minutes.

Time span of measurement: About 2 times as long as the retention time of amiodarone.

System suitability—

Test for required detectability: Pipet 5 mL of the standard solution, and add a mixture of water and acetonitrile for liquid chromatography (1:1) to make exactly 25 mL. Confirm that the peak area of amiodarone obtained from 10 μL of this solution is equivalent to 14 to 26% of that from 10 μL of the standard solution.

System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amiodarone are not less than 5000 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amiodarone is not more than 1.0%.

(6) Residual solvent—Being specified separately.

Loss on drying <2.4f> Not more than 0.5% (1 g, reduced pressure not exceeding 0.3 kPa, 50°C, 4 hours).

Residue on ignition <2.4g> Not more than 0.1% (1 g).

Assay Weigh accurately about 0.6 g of Amiodarone Hydrochloride, previously dried, dissolve in 40 mL of a mixture of acetic anhydride and acetic acid (100) (3:1), and titrate <2.5g> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 68.18 mg of C25H29I2NO3.HCl

Containers and storage Containers—Tight containers. Storage—Light-resistant.
Amiodarone Hydrochloride Tablets

アミオダロン塩酸塩

Amiodarone Hydrochloride Tablets contain not less than 93.0% and not more than 107.0% of the labeled amount of amiodarone hydrochloride (C$_{25}$H$_{29}$I$_2$NO$_3$.HCl: 681.77).

Method of preparation Prepare as directed under Tablets, with Amiodarone Hydrochloride.

Identification To 1 mL of the sample stock solution obtained in the Assay add the mobile phase to make 50 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits a maximum between 239 nm and 243 nm.

Uniformity of dosage units <6.02> Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Amiodarone Hydrochloride Tablets add 160 mL of the mobile phase, treat with ultrasonic waves for 10 minutes, add the mobile phase to make exactly 200 mL, and centrifuge. Pipet $V$ mL of the supernatant liquid, equivalent to about 1 mg of amiodarone hydrochloride (C$_{25}$H$_{29}$I$_2$NO$_3$.HCl), add the mobile phase to make exactly 50 mL, and use this solution as the sample solution. Separately, weigh accurately about 25 mg of amiodarone hydrochloride for assay, previously dried at 50°C for 4 hours under reduced pressure not exceeding 0.3 kPa, and dissolve in methanol to make exactly 100 mL. Prepare the test solution by adding methanol to 2 mL of the dissolution medium, add methanol to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, $A_T$ and $A_9$, of the sample solution and standard solution at 241 nm as directed under Ultraviolet-visible Spectrophotometry <2.24>, using a solution, prepared by adding methanol to 2 mL of the dissolution medium to make 20 mL, as the blank.

Dissolution rate (%) with respect to the labeled amount of amiodarone hydrochloride (C$_{25}$H$_{29}$I$_2$NO$_3$.HCl) $M_5 = M_5 \times A_T/A_9 \times V/V \times 1/C \times 36$

$M_5$: Amount (mg) of amiodarone for assay

C: Labeled amount (mg) of amiodarone hydrochloride (C$_{25}$H$_{29}$I$_2$NO$_3$.HCl) in 1 tablet

Assay Weigh accurately the mass of not less than 20 Amiodarone Hydrochloride Tablets, and powder. Weigh accurately a portion of the powder, equivalent to about 50 mg of amiodarone hydrochloride (C$_{25}$H$_{29}$I$_2$NO$_3$.HCl), add 80 mL of the mobile phase, treat with ultrasonic waves for 10 minutes, and add the mobile phase to make exactly 50 mL. Cenrifuge this solution, and use the supernatant liquid as the sample stock solution. Pipet 2 mL of the stock solution, add exactly 2 mL of the internal standard solution, add the mobile phase to make 50 mL, and use this solution as the sample solution. Separately, weigh accurately 25 mg of amiodarone hydrochloride for assay, previously dried at 50°C for 4 hours under reduced pressure not exceeding 0.3 kPa, and dissolve in the mobile phase to make exactly 50 mL. Pipet 2 mL of this solution, add exactly 2 mL of the internal standard solution, add the mobile phase to make 50 mL, and use this solution as the standard solution. Perform the test with 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and calculate the ratios, $Q_T$ and $Q_9$, of the peak area of amiodarone to that of the internal standard.

Amount (mg) of amiodarone hydrochloride (C$_{25}$H$_{29}$I$_2$NO$_3$.HCl) $M_5 = M_5 \times Q_T/Q_9 \times 2$

$M_5$: Amount (mg) of amiodarone hydrochloride for assay

Internal standard solution—A solution of chlorhexidine hydrochloride in the mobile phase (1 in 2500).

Operating conditions—Detector: An ultraviolet absorption photometer (wavelength: 242 nm).

Column: A stainless steel column 4 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about
50°C.

Mobile phase: A mixture of acetonitrile for liquid chromatography, a solution of sodium laurylsulfate (1 in 50) and phosphoric acid (750:250:1).

Flow rate: Adjust the flow rate so that the retention time of amiodarone is about 7 minutes.

System suitability—

System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the internal standard and amiodarone are eluted in this order with the resolution between these peaks not being less than 5.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of amiodarone to that of the internal standard is not more than 1.0%.

Containers and storage—Tight containers.

Storage—Light-resistant.

### Amitriptyline Hydrochloride

#### Description

Amitriptyline Hydrochloride occurs as colorless crystals or a white to pale yellow crystalline powder. It has a bitter taste and a numbing effect. It is freely soluble in water, in ethanol (95) and in acetic acid (100), soluble in acetic anhydride, and practically insoluble in diethyl ether.

The pH of a solution of Amitriptyline Hydrochloride (1 in 20) is between 4.0 and 5.0.

**Identification (1)** Dissolve 5 mg of Amitriptyline Hydrochloride in 3 mL of sulfuric acid: a red color develops. Add 5 drops of potassium dichromate TS to this solution: it turns dark brown.

**Identification (2)** Acidify 1 mL of a solution of Amitriptyline Hydrochloride (1 in 500) with 0.5 mL of dilute nitric acid, and add 1 drop of silver nitrate TS: a white, opalescent precipitate is produced.

**Identification (3)** Determine the absorption spectrum of a solution of Amitriptyline Hydrochloride (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum or the spectrum of a solution of Amitriptyline Hydrochloride RS prepared in the same manner as the sample solution: both spectra exhibit similar intensities of absorption at the same wavelengths.

**Melting point** <2.6D> 195 – 198°C

**Purity (1)** Clarity and color of solution—Dissolve 1.0 g of Amitriptyline Hydrochloride in 20 mL of water: the solution is clear and colorless.

**Identification (2)** Heavy metals <1.07>—Proceed with 2.0 g of Amitriptyline Hydrochloride according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

**Loss on drying** <2.4I> Not more than 0.5% (1 g, 105°C, 2 hours).

**Residue on ignition** <2.4G> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.5 g of Amitriptyline Hydrochloride, previously dried, dissolve in 50 mL of a mixture of acetic anhydride and acetic acid (100) (7:3), and titrate <2.5D> with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 31.39 mg of C20H23N.HCl

Containers and storage—Tight containers.

Storage—Light-resistant.

### Amitriptyline Hydrochloride Tablets

Amitriptyline Hydrochloride Tablets contain not less than 90.0% and not more than 110.0% of the labeled amount of amitriptyline hydrochloride (C20H23N.HCl: 313.86).

**Method of preparation** Prepare as directed under Tablets, with Amitriptyline Hydrochloride.

**Identification (1)** Weigh a quantity of powdered Amitriptyline Hydrochloride Tablets, equivalent to 0.1 g of Amitriptyline Hydrochloride according to the labeled amount. Add 10 mL of chloroform, shake thoroughly, and filter. Evaporate the filtrate on a water bath to about 2 mL, add diethyl ether until turbidity is produced, and allow to stand. Filter the crystals formed through a glass filter (G4), and proceed as directed in the Identification (1) and (2) under Amitriptyline Hydrochloride.

**Identification (2)** Determine the absorption spectrum of a solution of the crystals obtained in (1) (1 in 100,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits a maximum between 238 nm and 240 nm, and a minimum between 228 nm and 230 nm.

**Uniformity of dosage units** <6.02> Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Amitriptyline Hydrochloride Tablets add 50 mL of diluted methanol (1 in 2), shake to disintegrate the tablet, then add diluted methanol (1 in 2) to make exactly 100 mL, and filter. Discard the first 20 mL of the filtrate, pipet V mL of the subsequent filtrate, add methanol to make exactly V mL so that each mL contains about 10 μg of...
amitriptyline hydrochloride (C₂₀H₂₃N.HCl), and use this solution as the sample solution. Then, proceed as directed in the Assay.

Amount (mg) of amitriptyline hydrochloride (C₂₀H₂₃N.HCl) = \( M_6 \times A_T/\overline{A}_S \times V/V \times 1/20 \)

where

- \( M_6 \): Amount (mg) of Amitriptyline Hydrochloride RS

**Dissolution** (6.10)

When the test is performed at 50 revolutions per minute according to the Paddle method, using 900 mL of 2nd fluid for dissolution test as the dissolution medium, the dissolution rate in 60 minutes of Amitriptyline Hydrochloride Tablets is not less than 70%.

Start the test with 1 tablet of Amitriptyline Hydrochloride Tablets, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.8 µm. Discard the first 10 mL of the filtrate, pipet the subsequent \( V \) mL of the filtrate, add the dissolution medium to make exactly \( V \) mL so that each mL contains about 11 µg of amitriptyline hydrochloride (C₂₀H₂₃N.HCl) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 55 mg of Amitriptyline Hydrochloride RS, previously dried at 105°C for 2 hours, and dissolve in the dissolution medium to make exactly 250 mL. Pipet 5 mL of this solution, add the dissolution medium to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, \( A_T \) and \( A_S \), of the sample solution and standard solution at 239 nm as directed under Ultraviolet-visible Spectrophotometry (6.24).

Dissolution rate (％) with respect to the labeled amount of amitriptyline hydrochloride (C₂₀H₂₃N.HCl) = \( M_6 \times A_T/\overline{A}_S \times V/V \times 1/C \times 18 \)

where

- \( M_6 \): Amount (mg) of Amitriptyline Hydrochloride RS

**C: Labeled amount (mg) of amitriptyline hydrochloride (C₂₀H₂₃N.HCl) in 1 tablet**

**Assay**

Weigh accurately and powder not less than 20 Amitriptyline Hydrochloride Tablets. Weigh accurately a portion of the powder, equivalent to about 20 mg of amitriptyline hydrochloride (C₂₀H₂₃N.HCl), and add 75 mL of diluted methanol (1 in 2). After shaking for 30 minutes, add diluted methanol (1 in 2) to make exactly 100 mL, and filter. Discard the first 20-mL portion of the filtrate, measure exactly the subsequent 5-mL portion, add methanol to make exactly 100 mL, and use this solution as the sample solution. Separately, weigh accurately about 20 mg of Amitriptyline Hydrochloride RS, previously dried at 105°C for 2 hours, and dissolve in diluted methanol (1 in 2) to make exactly 100 mL. Measure exactly 5 mL of this solution, add methanol to make exactly 100 mL, and use this solution as the sample solution. Determine the absorbances, \( A_T \) and \( A_S \), of the sample solution and standard solution at 239 nm as directed under Ultraviolet-visible Spectrophotometry (6.24), respectively.

Amount (mg) of amitriptyline hydrochloride (C₂₀H₂₃N.HCl) = \( M_6 \times A_T/\overline{A}_S \)

where

- \( M_6 \): Amount (mg) of Amitriptyline Hydrochloride RS

**Containers and storage**

Containers—Tight containers.

**Amlexanox**

アンレキサノクス

C₁₆H₁₈N₂O₄: 298.29
2-Amino-7-(1-methylethyl)-5-oxo-5H-[1]benzopyran-2,3-b]pyridine-3-carboxylic acid [68302-37-8]

Amlexanox, when dried, contains not less than 98.0％ and not more than 102.0％ of C₁₆H₁₈N₂O₄.

**Description**

Amlexanox occurs as white to yellowish white crystals or crystalline powder. It is very slightly soluble in ethanol (99.5), and practically insoluble in water. It dissolves in diluted sodium hydroxide TS (1 in 3).

**Identification** (1)

Determine the absorption spectrum of a solution of Amlexanox in ethanol (99.5) (1 in 250,000) as directed under Ultraviolet-visible Spectrophotometry (6.24), and compare the spectrum with the Reference Spectrum or the spectrum of a solution of Amlexanox RS prepared in the same manner as the sample solution: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Amlexanox as directed in the potassium bromide disk method under Infrared Spectrophotometry (6.25), and compare the spectrum with the Reference Spectrum or the spectrum of Amlexanox RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Purity** (1)

Chloride (6.07) — Dissolve 1.0 g of Amlexanox in 20 mL of water and 10 mL of sodium hydroxide TS, add 15 mL of dilute nitric acid and water to make 50 mL, centrifuge, and then filter the supernatant liquid. To 25 mL of this filtrate add water to make 50 mL. Perform the test using this solution as the test solution. The control solution consists of 5 mL of sodium hydroxide TS, 7.5 mL of dilute nitric acid, 0.30 mL of 0.01 mol/L hydrochloric acid VS, and water added to make 50 mL (not more than 0.021％).

(2) Heavy metals (6.07) — Proceed with 1.0 g of Amlexanox according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(3) Related substances — (i) Dissolve 30 mg of Amlexanox in 50 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add the mobile phase to make exactly 50 mL. Pipet 1 mL of this solution, add the mobile phase to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 µL each of the sample solution and standard solution as directed under Liquid Chromatography (6.01) according to the following conditions. Determine each peak area of these solutions by the automatic integration method: the area of the peak other than amlexanox obtained from the sample solution is not larger than 2 times the peak area of amlexanox from the standard solution.

**Operating conditions** —
The detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay.

Time span of measurement: Until completion of the elution of amlexanox beginning after the solvent peak.

System suitability—
Test for required detectability: Pipet 10 mL of the standard solution, and add the mobile phase to make exactly 100 mL. Confirm that the peak area of amlexanox obtained from 10 μL of this solution is equivalent to 7 to 13% of that from 10 μL of the standard solution.

System performance: Proceed as directed in the system suitability in the Assay.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amlexanox is not more than 2.0%.

(ii) Dissolve 30 mg of Amlexanox in 50 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add the mobile phase to make exactly 50 mL. Pipet 1 mL of this solution, add the mobile phase to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL of each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and determine each peak area of these solutions by the automatic integration method: the area of the peak other than amlexanox obtained from the sample solution is not larger than 2 times the peak area of amlexanox from the standard solution.

Operating conditions—
Detector, column, and column temperature: Proceed as directed in the operating conditions in the Assay.

Mobile phase: Dissolve 7.2 g of disodium hydrogen phosphate dodecahydrate in water to make 1000 mL. Adjust the pH of this solution to 8.0 by adding a solution prepared by dissolving 3.1 g of sodium dihydrogen phosphate dihydrate in 1000 mL of water. To 400 mL of this solution add 600 mL of acetonitrile.

Flow rate: To 15 mL of a solution of benzophenone in the mobile phase (3 in 1,000,000) add the mobile phase to make 20 mL. Adjust the flow rate so that the retention time of benzophenone is about 6.5 minutes when the test with 10 μL of this solution under the conditions described above.

Time span of measurement: About 3 times as long as the retention time of benzophenone, beginning after the peak of amlexanox.

System suitability—
Test for required detectability: Pipet 5 mL of the standard solution, and add the mobile phase to make exactly 50 mL. Confirm that the peak area of amlexanox obtained from 10 μL of this solution is equivalent to 7 to 13% of that from 10 μL of the standard solution.

System performance: Pipet 1 mL of the sample solution, and add the mobile phase to make 100 mL. To 5 mL of this solution add 15 mL of the solution of benzophenone in the mobile phase (3 in 1,000,000). When perform the test with 10 μL of this solution according to the above conditions, amlexanox and benzophenone are eluted in this order with the resolution between these peaks being not less than 10.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amlexanox is not more than 2.0%.

(iii) The total amount of related substances, when calculated according to the following formula, is not more than 0.5%.

\[
\text{Total amount} \times \frac{1}{10} = \frac{(A_{T1}/A_{S1}) + (A_{T2}/A_{S2})}{2/0.1} = T1 \times Q1 = A_{T3} \times \frac{Q2}{Q3}
\]

\[
M \times \text{Amount (mg) of Amlexanox RS}
\]

Internal standard solution—A solution of 3-nitroaniline in the mobile phase (1 in 4000).

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4.0 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: Dissolve 17.9 g of disodium hydrogen phosphate dodecahydrate in water to make 1000 mL. Adjust the pH of this solution to 8.0 by adding a solution prepared by dissolving 7.8 g of sodium dihydrogen phosphate dihydrate in 1000 mL of water. To 760 mL of this solution add 240 mL of acetonitrile.

Flow rate: Adjust the flow rate so that the retention time of amlexanox is about 10 minutes.

System suitability—
System performance: When the procedure is run with 10 μL of the standard solution according to the above conditions, amlexanox and the internal standard are eluted in this order with the resolution between these peaks being not less than 2.0.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above conditions, the relative standard deviation of the ratio of the peak area of amlexanox to that of the internal standard is not
Containers and storage  Containers—Well-closed containers.

Amlexanox Tablets
アンレキサノクス錠

Amlexanox Tablets contain not less than 93.0% and not more than 107.0% of the labeled amount of amlexanox (C\(_{16}H_{14}N_2O_4\): 298.29).

Method of preparation  Prepare as directed under Tablets, with Amlexanox.

Identification  (1) Take an amount of powdered Amlexanox Tablets, equivalent to 10 mg of Amlexanox according to the labeled amount, add 100 mL of ethanol (99.5), shake vigorously, and filter. Pipet 1 mL of the filtrate, add 25 mL of ethanol (99.5), and use this solution as the sample solution. Determine the absorption spectrum of the sample solution as directed under Ultraviolet-visible Spectrophotometry 2.24: it exhibits absorption maxima between 240 nm and 244 nm, so there is about 167 \(\times 6.02\) \(\mu g\) of amlexanox (C\(_{16}H_{14}N_2O_4\)) per 1 mg of Amlexanox.

Uniformity of dosage units  <6.02> Perform the test according to the following method: it meets the requirement of the Content uniformity test.

Take 1 tablet of Amlexanox Tablets, add exactly 0.6 mL of the internal standard solution per 1 mg of amlexanox (C\(_{16}H_{14}N_2O_4\)), add the mobile phase to make exactly \(V\) mL so there is about 167 \(\mu g\) of amlexanox (C\(_{16}H_{14}N_2O_4\)) per 1 mL, disintegrate the tablet, and then shake vigorously for 5 minutes. Centrifuge this solution, and use the supernatant liquid as the sample solution. Separately, weigh accurately about 30 mg of Amlexanox RS, previously dried at 105°C for 2 hours, and dissolve in 2 mL of dilute sodium hydroxide TS, add the dissolution medium to make exactly 50 mL. Pipet 1 mL of this solution, add the dissolution medium to make exactly 100 mL, and use this solution as the standard solution. Determine the absorbances, \(A_T\) and \(A_S\), at 350 nm of the sample solution and standard solution as directed under Ultraviolet-visible Spectrophotometry 2.24.

Dissolution rate (%) with respect to the labeled amount of amlexanox (C\(_{16}H_{14}N_2O_4\))

\[
M_S = M_A \times \frac{V}{Q} \times \frac{1/2}{1/18} \\
M_S: \text{Amount (mg) of Amlexanox RS}
\]

Internal standard solution—A solution of 3-nitroaniline in the mobile phase (1 in 500).

Containers and storage  Containers—Tight containers.

Amlodipine Besilate
アムロジピンベシル酸塩

Amlodipine Besilate contains not less than 98.0% and not more than 102.0% of C\(_{20}H_{25}ClN_2O_5\), C\(_6H_6O_3\)S, and enantiomer C\(_{20}H_2ClN_2O_5\), C\(_6H_6O_3\)S: 567.05
calculated on the anhydrous basis.

**Description**
Amlodipine Besilate occurs as a white to yellowish white crystalline powder.

It is freely soluble in methanol, sparingly soluble in ethanol (99.5), and slightly soluble in water.

A solution of Amlodipine Besilate in methanol (1 in 100) shows no optical rotation.

Melting point: about 198°C (with decomposition).

**Identification (1)**
Determine the absorption spectrum of a solution of Amlodipine Besilate in 0.01 mol/L hydrochloric acid-methanol TS (1 in 40,000) as directed under Ultraviolet-visible Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum or the spectrum of a solution of Amlodipine Besilate RS prepared in the same manner as the sample solution: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Amlodipine Besilate as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum or the spectrum of Amlodipine Besilate RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) To 30 mg of Amlodipine Besilate add 0.1 g of sodium nitrate and 0.1 g of anhydrous sodium carbonate, mix, and gradually ignite. After cooling, dissolve the residue in 2 mL of dilute hydrochloric acid and 10 mL of water, filter if necessary, and add barium chloride TS: a white precipitate is formed.

**Purity (1)**
Heavy metals <1.07)—Proceed with 1.0 g of Amlodipine Besilate according to Method 4, and perform the test. Prepare the control solution with 2.5 mL of Standard Lead Solution (not more than 25 ppm).

(2) Related substances—Dissolve 0.10 g of Amlodipine Besilate in 50 mL of a mixture of water and acetonitrile (1:1), and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add the mixture of water and acetonitrile (1:1) to make exactly 100 mL. Pipet 3 mL of this solution, add the mixture of water and acetonitrile (1:1) to make exactly 10 mL, and use this solution as the standard solution. Perform the test with exactly 10 µL of each of the sample solution and standard solution as directed under Liquid Chromatography <2.47> according to the following conditions, and determine each peak area by the automatic integration method: the area of the peak having the relative retention time of 0.90 with respect to amlodipine, obtained from the sample solution is not larger than the peak area of amlodipine from the standard solution, and the area of the peak other than amlodipine, other than benzenesulfonic acid having the relative retention time of about 0.15 with respect to amlodipine, and other than the peak mentioned above is not larger than 1/3 times the peak area of amlodipine from the standard solution. Furthermore, total peak area for peaks other than amlodipine and benzenesulfonic acid of the sample solution is not larger than 2.7 times the peak area of amlodipine from the standard solution.

**Operating conditions—**
Detector: An ultraviolet absorption photometer (wavelength: 237 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (3 µm in particle diameter).

Flow rate: 1.0 mL per minute.

Time span of measurement: About 3 times as long as the retention time of amlodipine, beginning after the solvent peak.

**System suitability—**
Test for required detectability: Pipet 1 mL of the standard solution, and add a mixture of water and acetonitrile (1:1) to make exactly 10 mL. Confirm that the peak area of amlodipine obtained with 10 µL of this solution is equivalent to 7 to 13% of that with 10 µL of the standard solution.

**System performance:**
When the procedure is run with 10 µL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amlodipine are not less than 70,000 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 µL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amlodipine is not more than 2.0%.

(3) Residual solvent—Being specified separately.

**Water** <2.48> Not more than 0.5% (1 g, volumetric titration, direct titration).

**Residue on ignition** <2.44> Not more than 0.2% (1 g).

**Assay**
Weigh accurately about 35 mg each of Amlodipine Besilate and Amlodipine Besilate RS (separately determine the water <2.48> using the same manner as Amlodipine Besilate), dissolve them separately in the mobile phase to make exactly 250 mL. Pipet 5 mL each of these solutions, add exactly 5 mL each of the internal standard solution, add the mobile phase to make 25 mL, and use these solutions as the sample solution and standard solution. Perform the test with 20 µL of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions, and calculate the ratios, Q1 and Q5, of the peak area of amlodipine to that of the internal standard.

\[
\text{Amount (mg) of C}_{20}\text{H}_{25}\text{ClN}_{2}\text{O}_{5}.\text{C}_{4}\text{H}_{6}\text{O}_{3}\text{S} = M_S \times \frac{Q_1}{Q_5}
\]

\[
M_S: \text{Amount (mg) of Amlodipine Besilate RS, calculated on the anhydrous basis}
\]

**Internal standard solution—**A solution of isobutyl parahydroxybenzoate in the mobile phase (3 in 20,000).

**Operating conditions—**
Detector: An ultraviolet absorption photometer (wavelength: 237 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadeccylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: A mixture of methanol and a solution of potassium dihydrogen phosphate (41 in 10,000) (13:7).

Flow rate: Adjust the flow rate so that the retention time of amloidipine is about 8 minutes.

System suitability—

System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions, amloidipine and the internal standard are eluted in this order with the resolution between these peaks being not less than 3.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of amloidipine to that of the internal standard is not more than 1.0%.

Containers and storage—Containers—Well-closed containers.

Storage—Light-resistant.

Amloidipine Besilate Tablets

アムロジピンベシル酸塩錠

Amloidipine Besilate Tablets contain not less than 95.0% and not more than 105.0% of the labeled amount of amloidipine besilate (C20H25ClN2O5.C6H6O3S: 567.05).

Method of preparation—Prepare as directed under Tablets, with Amloidipine Besilate.

Identification—To a quantity of powdered Amloidipine Besilate Tablets, equivalent to 2.5 mg of Amloidipine Besilate according to the labeled amount, add 100 mL of 0.01 mol/L hydrochloric acid-methanol TS, shake vigorously, and filter. Determine the absorption spectrum of the filtrate as directed under Ultraviolet-visible Spectrophotometry <2.24>: it exhibits maxima between 235 nm and 239 nm, and between 358 nm and 362 nm.

Uniformity of dosage units—Perform the test according to the following method: it meets the requirement of the Content uniformity test.

To 1 tablet of Amloidipine Besilate Tablets add 10 mL of water to disintegrate, disperse with the aid of ultrasonic waves with occasional shaking, add the mobile phase to make exactly V mL so that each mL contains about 69 μg of amloidipine besilate (C20H25ClN2O5.C6H6O3S), and shake for 60 minutes. Centrifuge this solution, pipet 10 mL of the supernatant liquid, add exactly 5 mL of the internal standard solution, add the mobile phase to make 25 mL, and use this solution as the sample solution. Proceed as directed in the Assay.

Amount (mg) of amloidipine besilate

\[ M_5 = \frac{M_S \times Q_r}{Q_S \times V} \times 500 \]

M₅: Amount (mg) of Amloidipine Besilate RS, calculated on the anhydrous basis

Internal standard solution—A solution of isobutyl parahydroxybenzoate in the mobile phase (3 in 20,000).

Dissolution—Being specified separately.

Assay—To 20 Amloidipine Besilate Tablets add 100 mL of water to disintegrate, disperse with the aid of ultrasonic waves with occasional shaking, add the mobile phase to make exactly 1000 mL, and shake for 60 minutes. Centrifuge this solution, pipet a volume of the supernatant liquid, and use this solution as the sample solution. Separately, weigh accurately about 35 mg of Amloidipine Besilate RS (separately, determine the water <2.46> in the same manner as Amloidipine Besilate), and dissolve in the mobile phase to make exactly 250 mL. Pipet 5 mL of this solution, add exactly 5 mL of the internal standard solution, add the mobile phase to make 25 mL, and use this solution as the standard solution. Perform the test with 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and calculate the ratios, Qₑ and Qₘ, of the peak area of amloidipine to that of the internal standard.

Amount (mg) of amloidipine besilate

\[ M_5 = \frac{M_S \times Q_r}{Q_S} \times 1/50 \]

M₅: Amount (mg) of Amloidipine Besilate RS, calculated on the anhydrous basis

Internal standard solution—A solution of isobutyl parahydroxybenzoate in the mobile phase (3 in 20,000).

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 237 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadeccylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 25°C.

Mobile phase: A mixture of methanol and potassium dihydrogen phosphate (41 in 10,000) (13:7).

Flow rate: Adjust the flow rate so that the retention time of amloidipine is about 8 minutes.

System suitability—

System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions, amloidipine and the internal standard are eluted in this order with the resolution between these peaks being not less than 5.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of amloidipine to that of the internal standard is not more than 1.0%.

Containers and storage—Containers—Well-closed containers.
Ammonia Water

アンモニア水

Ammonia Water contains not less than 9.5 w/v% and not more than 10.5 w/v% of ammonia (NH₃: 17.03).

**Description** Ammonia Water occurs as a clear, colorless liquid, having a very pungent, characteristic odor. It is alkaline.

Specific gravity d₃₀: 0.95 – 0.96

**Identification** (1) Hold a glass rod moistened with hydrochloric acid near the surface of Ammonia Water: dense white fumes are produced.

(2) Hold moistened red litmus paper near the surface of Ammonia Water: it turns blue.

**Purity** (1) Residue on evaporation—Evaporate 10.0 mL of Ammonia Water to dryness, and dry the residue at 105°C for 1 hour: the mass of the residue is not more than 2.0 mg.

(2) Heavy metals <1.07>—Evaporate 5.0 mL of Ammonia Water to dryness on a water bath, add 1 mL of dilute hydrochloric acid to the residue, and evaporate to dryness. Dissolve the residue in 2 mL of dilute acetic acid, add water to make 50 mL, and perform the test using this solution as the test solution. Prepare the control solution with 2.5 mL of Standard Lead Solution, 2 mL of dilute acetic acid and water to make 50 mL (not more than 5 ppm).

(3) Potassium permanganate-reducing substances—To 10.0 mL of Ammonia Water add 40 mL of dilute sulfuric acid while cooling, and add 0.10 mL of 0.02 mol/L potassium permanganate VS: the red color of the potassium permanganate does not disappear within 10 minutes.

**Assay** Measure exactly 5 mL of Ammonia Water, add 25 mL of water, and titrate <2.30> with 0.5 mol/L sulfuric acid VS (indicator: 2 drops of methyl red TS).

Each mL of 0.5 mol/L sulfuric acid VS = 17.03 mg of NH₃

**Containers and storage** Containers—Tight containers.

Storage—Not exceeding 30°C.

Amobarbital

アモバルビタール

C₁₁H₁₈N₂O₃: 226.27
5-Ethyl-5-(3-methylbutyl)pyrimidine-2,4,6(1H,3H,5H)-trione
[57-43-2]

Amobarbital, when dried, contains not less than 99.0% of C₁₁H₁₈N₂O₃.

**Description** Amobarbital occurs as white crystals or crystalline powder. It is odorless, and has a slightly bitter taste. It is freely soluble in ethanol (95), in acetone and in diethyl ether, sparingly soluble in chloroform, and practically insoluble in water.

It dissolves in sodium hydroxide TS and in sodium carbonate TS.

The pH of a saturated solution of Amobarbital is between 5.0 and 5.6.

**Identification** (1) Boil 0.2 g of Amobarbital with 10 mL of sodium hydroxide TS: the gas evolved changes moistened litmus paper to blue.

(2) Dissolve 0.05 g of Amobarbital in 2 to 3 drops of ammonia-ammonium chloride buffer solution, pH 10.7, and 5 mL of diluted pyridine (1 in 10). Add 5 mL of chloroform and 0.3 mL of copper (II) sulfate TS to the solution: a red-purple precipitate is produced in the aqueous layer. Shake the mixture: a red-purple color is produced in the chloroform layer.

(3) To 0.4 g of Amobarbital add 0.1 g of anhydrous sodium carbonate and 4 mL of water, shake, and add a solution of 0.3 g of 4-nitrobenzyl chloride in 7 mL of ethanol (95). Heat the mixture on a water bath for 30 minutes under a reflux condenser, and allow to stand for 1 hour. Filter the crystals produced, wash with 7 mL of sodium hydroxide TS and a small portion of water, recrystallize from ethanol, and dry at 105°C for 30 minutes: the crystals so obtained melt <2.60> between 168°C and 173°C or between 150°C and 154°C.

**Melting point** <2.60> 157 – 160°C

**Purity** (1) Clarity and color of solution—Dissolve 0.5 g of Amobarbital in 5 mL of sodium hydroxide TS: the solution is clear and colorless.

(2) Chloride <1.03>—Dissolve 0.30 g of Amobarbital in 20 mL of acetone, and add 6 mL of dilute nitric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: take 0.30 mL of 0.01 mol/L hydrochloric acid VS, 20 mL of acetone and 6 mL of dilute nitric acid, and add water to make 50 mL (not more than 0.035%).

(3) Sulfate <1.14>—Dissolve 0.40 g of Amobarbital in 20 mL of acetone, and add 1 mL of dilute hydrochloric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: take 0.40 mL of 0.005 mol/L hydrochloric acid VS, 20 mL of acetone and 1 mL of dilute hydrochloric acid, and add water to make 50 mL (not more than 0.048%).

(4) Heavy metals <1.07>—Proceed with 1.0 g of Amobarbital according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(5) Readily carbonizable substances <1.15>—Perform the test with 0.5 g of Amobarbital. The solution is not more colored than Matching Fluid A.

**Loss on drying** <2.4> Not more than 1.0% (1 g, 105°C, 4 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.5 g of Amobarbital, previously dried, and dissolve in 5 mL of ethanol (95) and 50 mL of chloroform. Titrate <2.50> with 0.1 mol/L potassium hydroxide-ethanol VS until the color of the solution changes
from yellow through light blue to purple (indicator: 1 mL of alizarin yellow GG-thymolphthalein TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L potassium hydroxide-ethanol VS = 22.63 mg of C_{11}H_{17}N_{2}NaO_{3}

Containers and storage Containers—Well-closed containers.

**Amobarbital Sodium for Injection**

注射用アモバルビタールナトリウム

![Chemical Structure](image)

C_{11}H_{17}N_{2}NaO_{3}: 248.25
Monosodium 5-ethyl-5-(3-methylbutyl)-4,6-dioxo-1,4,5,6-tetrahydropyrimidin-2-olate [64-43-7]

Amobarbital Sodium for Injection is a preparation for injection which is dissolved before use.

When dried, it contains not less than 98.5% of amobarbital sodium (C_{11}H_{17}N_{2}NaO_{3}), and not less than 92.5% and not more than 107.5% of the labeled amount of amobarbital sodium (C_{11}H_{17}N_{2}NaO_{3}).

**Method of preparation** Prepare as directed under Injections.

**Description** Amobarbital Sodium for Injection occurs as white crystals or a crystalline powder. It is odorless, and has a bitter taste.

It is freely soluble in water and in ethanol (95), and practically insoluble in diethyl ether and in chloroform.

The pH of its solution (1 in 10) is between 10.0 and 11.0. It is hygroscopic.

**Identification** (1) Dissolve 1.5 g of Amobarbital Sodium for Injection in 20 mL of water, and add 10 mL of dilute hydrochloric acid with stirring: a white precipitate is produced. Collect the precipitate, wash with four 10-mL portions of water, and dry at 105°C for 3 hours: it melts <2.60> between 157°C and 160°C. With this precipitate, proceed as directed in the Identification under Amobarbital.

(2) Ignite 0.5 g of Amobarbital Sodium for Injection, cool, and dissolve the residue in 10 mL of water: the solution responds to the Qualitative Tests <1.09> (1) for sodium salt.

**Purity** (1) Clarity and color of solution—Dissolve 1.0 g of Amobarbital Sodium for Injection in 10 mL of freshly boiled and cooled water: the solution is clear and colorless.

(2) Chloride <1.09>—Dissolve 1.0 g of Amobarbital Sodium for Injection in 49 mL of water, add 1 mL of acetic acid (100), shake, and filter. Discard the first 10 mL of the filtrate, and to the subsequent 30 mL of the filtrate add 6 mL of dilute nitric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: to 0.30 mL of 0.01 mol/L hydrochloric acid VS add 0.5 mL of acetic acid (100), 6 mL of dilute nitric acid and water to make 50 mL (not more than 0.018%).

(3) Sulfate <1.14>—Dissolve 2.0 g of Amobarbital Sodium for Injection in 49 mL of water, add 1 mL of acetic acid (100), shake, and filter. Discard the first 10 mL of the filtrate, and to the subsequent 25 mL of the filtrate add 2.5 mL of dilute hydrochloric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: to 0.40 mL of 0.005 mol/L sulfuric acid VS add 0.5 mL of acetic acid (100), 1 mL of dilute hydrochloric acid and water to make 50 mL (not more than 0.019%).

(4) Heavy metals <1.07>—Dissolve 2.0 g of Amobarbital Sodium for Injection in 45 mL of water, add 5 mL of dilute hydrochloric acid, shake vigorously, and warm on a water bath for 2 minutes with occasional shaking. Cool, add 30 mL of water, shake, and filter. Discard the first 10 mL of the filtrate, add 1 drop of phenolphthalein TS to the subsequent 40 mL of the filtrate, add ammonia TS until a slight red color develops, and add 2.5 mL of dilute hydrochloric acid and water to make 50 mL. Perform the test using this solution as the test solution. Prepare the control solution as follows: to 2.5 mL of dilute hydrochloric acid add 1 drop of phenolphthalein TS, add ammonia TS until a pale red color develops, and add 2.5 mL of dilute acetic acid, 2.0 mL of Standard Lead Solution and water to make 50 mL (not more than 20 ppm).

(5) Neutral or basic substances—Dissolve about 1 g of Amobarbital Sodium for Injection, accurately weighed, in 10 mL of water and 5 mL of sodium hydroxide TS, then add 40 mL of chloroform, and shake well. Separate the chloroform layer, wash with two 5-mL portions of water, and filter. Evaporate the filtrate on a water bath to dryness, and dry the residue at 105°C for 1 hour: the mass of the residue is not more than 0.30%.

(6) Readily carbonizable substances <1.15>—Perform the test with 0.5 g of Amobarbital Sodium for Injection: the solution is not more colored than Matching Fluid A.

**Loss on drying** <2.41> Not more than 1.0% (1 g, 105°C, 4 hours).

**Assay** Weigh accurately the contents of not less than 10 samples of Amobarbital Sodium for Injection. Weigh accurately about 0.5 g of the contents, previously dried, transfer to a separator, dissolve in 20 mL of water, add 5 mL of ethanol (95) and 10 mL of dilute hydrochloric acid, and extract with 50 mL of chloroform, then with three 25-mL portions of chloroform. Combine the chloroform extracts, wash with two 5-mL portions of water, and extract the washings with two 10-mL portions of chloroform. Filter the combined chloroform extracts into a conical flask, and wash the filter paper with three 5-mL portions of chloroform. Combine the filtrate and the washings, and add 10 mL of ethanol (95). Titrate <2.30> with 0.1 mol/L potassium hydroxide-ethanol VS until the color of the solution changes from yellow through light blue to purple (indicator: 2 mL of alizarin yellow GG-thymolphthalein TS). Perform a blank determination with a mixture of 160 mL of chloroform and 30 mL of ethanol (95), and make any necessary correction.

Each mL of 0.1 mol/L potassium hydroxide-ethanol VS = 24.83 mg of C_{11}H_{17}N_{2}NaO_{3}

Containers and storage Containers—Hermetic containers.
Amosulalol Hydrochloride

**Description**
Amosulalol Hydrochloride occurs as white crystals or a white crystalline powder. It has a bitter taste. It is very soluble in formic acid, freely soluble in methanol, and sparingly soluble in water and in ethanol (99.5). It is hygroscopic.

A solution of Amosulalol Hydrochloride in methanol (1 in 100) shows no optical rotation.

**Identification**
(1) Determine the absorption spectrum of a solution of Amosulalol Hydrochloride (1 in 20,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Amosulalol Hydrochloride as directed in the potassium chloride disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) A solution of Amosulalol Hydrochloride (1 in 100) responds to the Qualitative Tests <1.09> for chloro.

**Melting point**
<2.60> 158 – 162°C

**Purity**
(1) Heavy metals <1.07>—Place 1.0 g of Amosulalol Hydrochloride in a porcelain crucible, add 1.5 mL of sulfuric acid, cover loosely, and heat gently to carbonize. After cooling, add 2 mL of nitric acid, heat carefully until white fumes no longer are evolved, and then heat intensely to 500 – 600°C to incinerate. After cooling, add 2 mL of hydrochloric acid, proceed according to Method 2, and perform the test. The control solution, processed in the same manner as the test solution using the same amounts of reagents, is prepared by combining 2.0 mL of Standard Lead Solution and water to make 50 mL (not more than 20 ppm).

(2) Related substances—Dissolve 0.10 g of Amosulalol Hydrochloride in 20 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 200 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine each peak area of both solutions by the automatic integration method: the total area of the peaks other than amosulalol obtained from the sample solution is not larger than 2/5 times the peak area of amosulalol from the standard solution.

**Operating conditions**

- Detector: An ultraviolet absorption photometer (wavelength: 272 nm).
- Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
- Column temperature: A constant temperature of about 30°C.
- Mobile phase: Dissolve 1.36 g of potassium dihydrogen phosphate in water to make 1000 mL, and adjust to pH 5.7 by adding a solution prepared by dissolving 3.58 g of disodium hydrogen phosphate dodecahydrate in water to make 1000 mL. To 670 mL of this solution add 330 mL of acetonitrile.
- Flow rate: Adjust the flow rate so that the retention time of amosulalol is about 7 minutes.
- Time span of measurement: About 2 times as long as the retention time of amosulalol, beginning after the solvent peak.

**System suitability**
- Test for required detectability: Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 10 mL. Confirm that the peak area of amosulalol obtained with 10 μL of this solution is equivalent to 7 to 13% of that with 10 μL of the standard solution.
- System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amosulalol are not less than 4000 and not more than 1.7, respectively.
- System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amosulalol is not more than 1.0%.

**Water** <2.48> Not more than 4.0% (1 g, volumetric titration, direct titration).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay**
Weigh accurately about 0.6 g of Amosulalol Hydrochloride, dissolve in 3 mL of formic acid, add 80 mL of a mixture of acetic acid (100) and acetic anhydride (3:2), and titrate <2.50> within 5 minutes with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination using the same procedure, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 41.69 mg of C_{18}H_{24}N_{2}O_{5}S.HCl

**Containers and storage**
Containers—Tight containers.
Amosulalol Hydrochloride Tablets

アモスラロール塩酸塩錠

Amosulalol Hydrochloride Tablets contain not less than 95.0% and not more than 105.0% of the labeled amount of amosulalol hydrochloride \((\text{C}_{18}\text{H}_{24}\text{N}_{2}\text{O}_{5}\text{S.HCl})\) (416.92).

**Method of preparation** Prepare as directed under Tablets, with Amosulalol Hydrochloride.

**Identification** To a quantity of powdered Amosulalol Hydrochloride Tablets, equivalent to 50 mg of Amosulalol Hydrochloride according to the labeled amount, add 25 mL of 0.1 mol/L hydrochloric acid TS, shake well, and then centrifuge. To 2.5 mL of the supernatant liquid add water to make 100 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry \(<2.24\text{›}\) it exhibits a maximum between 270 nm and 274 nm, and a shoulder between 275 nm and 281 nm.

**Uniformity of dosage units** \(<6.02\text{›}\) Perform the test according to the following method: it meets the requirement of the Content uniformity test.

Take 1 tablet of Amosulalol Hydrochloride Tablets, disintegrate by adding 2 mL of 0.1 mol/L hydrochloric acid TS, add 15 mL of methanol, and shake well. Add methanol to make exactly \(V\) mL so that each mL contains about 0.4 mg of amosulalol hydrochloride \((\text{C}_{18}\text{H}_{24}\text{N}_{2}\text{O}_{5}\text{S.HCl})\), and centrifuge. Pipet 5 mL of the supernatant liquid, add exactly 2 mL of the internal standard solution and the mobile phase to make 20 mL, and use this solution as the sample solution. Separately, weigh accurately about 20 mg of amosulalol hydrochloride for assay (separately determine the water \(<2.49\text{›}\) in the same manner as Amosulalol Hydrochloride), and dissolve in methanol to make exactly 50 mL. Pipet 5 mL of this solution, add exactly 2 mL of the internal standard solution, add the mobile phase to make 20 mL, and use this solution as the standard solution. Then, proceed as directed in the Assay. 

\[
\text{Amount (mg) of amosulalol hydrochloride (C}_{18}\text{H}_{24}\text{N}_{2}\text{O}_{5}\text{S.HCl}) \quad M_5 = \frac{M_i}{Q_i/Q_s} \times \frac{V}{50}
\]

\(M_5\): Amount (mg) of amosulalol hydrochloride for assay, calculated on the anhydrous basis

**Internal standard solution**—A solution of ethyl parahydroxybenzoate in methanol (1 in 6250).

**Dissolution** \(<6.10\text{›}\) When the test is performed at 50 revolutions per minute according to the Paddle method, using 900 mL of water as the dissolution medium, the dissolution rate in 30 minutes of Amosulalol Hydrochloride Tablets is not less than 75%.

Start the test with 1 tablet of Amosulalol Hydrochloride Tablets, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.5 \(\mu\)m. Discard the first 10 mL of the filtrate, pipet \(V\) mL of the subsequent filtrate, add water to make exactly \(V\) mL so that each mL contains about 5.5 \(\mu\)g of amosulalol hydrochloride \((\text{C}_{18}\text{H}_{24}\text{N}_{2}\text{O}_{5}\text{S.HCl})\) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 22 mg of amosulalol hydrochloride for assay (separately determine the water \(<2.49\text{›}\) in the same manner as Amosulalol Hydrochloride), and dissolve in water to make exactly 200 mL. Pipet 5 mL of this solution, add water to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 50 \(\mu\)L each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01\text{›}\) according to the following conditions, and determine the amosulalol peak areas, \(A_T\) and \(A_s\), of both solutions.

\[
\text{Dissolution rate (\%)} = \left( \frac{A_T}{A_s} \right) \times \frac{A_i/\sqrt{A_s} \times V/V \times 1/C \times 45/2}{M_i}
\]

\(M_i\): Amount (mg) of amosulalol hydrochloride for assay, calculated on the anhydrous basis

\(C\): Labeled amount (mg) of amosulalol hydrochloride \((\text{C}_{18}\text{H}_{24}\text{N}_{2}\text{O}_{5}\text{S.HCl})\) in 1 tablet

**Operating conditions**—

Detector: An ultraviolet absorption photometer (wavelength: 272 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 \(\mu\)m in particle diameter).

Column temperature: A constant temperature of about 30°C.

Mobile phase: Dissolve 1.36 g of potassium dihydrogen phosphate in water to make 1000 mL, and adjust to pH 5.7 by adding a solution prepared by dissolving 3.58 g of disodium hydrogen phosphate dodecahydrate in water to make 1000 mL. To 670 mL of this solution add 330 mL of acetonitrile.

Flow rate: Adjust the flow rate so that the retention time of amosulalol is about 5 minutes.

**System suitability**—

System performance: When the procedure is run with 50 \(\mu\)L of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amosulalol are not less than 4000 and not more than 1.7, respectively.

System repeatability: When the test is repeated 6 times with 50 \(\mu\)L of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amosulalol is not more than 1.8%.

**Assay** Take 10 Amosulalol Hydrochloride Tablets, add 20 mL of 0.1 mol/L hydrochloric acid TS, and shake well to disintegrate. Add 120 mL of methanol, again shake well, add methanol to make exactly 200 mL, and then centrifuge. Pipet a volume of supernatant liquid corresponding to about 5 mg of amosulalol hydrochloride \((\text{C}_{18}\text{H}_{24}\text{N}_{2}\text{O}_{5}\text{S.HCl})\), add exactly 5 mL of the internal standard solution, add the mobile phase to make 50 mL, and use this solution as the sample solution. Separately, weigh accurately about 25 mg of amosulalol hydrochloride for assay (separately determine the water \(<2.49\text{›}\) in the same manner as Amosulalol Hydrochloride), and dissolve in methanol to make exactly 25 mL. Pipet 5 mL of this solution, add exactly 5 mL of the internal standard solution, add the mobile phase to make 50 mL, and use this solution as the standard solution. Perform the test with 10 \(\mu\)L each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01\text{›}\) according to
the following conditions, and calculate the ratios, \( Q_1 \) and \( Q_2 \), of the peak area of amosulalol to that of the internal standard.

Amount (mg) of amosulalol hydrochloride
\[
(C_{18}H_{24}N_{2}O_{5}S.HCl) = M_5 \times Q_2/Q_3 \times 1/5
\]

\( M_5 \): Amount (mg) of amosulalol hydrochloride for assay, calculated on the anhydrous basis

**Internal standard solution**—A solution of ethyl parahydroxybenzoate in methanol (1 in 6250).

**Operating conditions**—
Detector: An ultraviolet absorption photometer (wavelength: 272 nm).
Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 \( \mu \)m in particle diameter).
Column temperature: A constant temperature of about 25°C.
Mobile phase: A mixture of diluted acetic acid (100) (1 in 25), acetonitrile and a solution of ammonium acetate (1 in 250) (5:3:2).
Flow rate: Adjust the flow rate so that the retention time of amosulalol is about 4 minutes.

**System suitability**—
- System performance: When the procedure is run with 10 \( \mu \)L of the standard solution under the above operating conditions, amosulalol and the internal standard are eluted in this order with the resolution between these peaks being not less than 7.
- System repeatability: When the test is repeated 6 times with 10 \( \mu \)L of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of amosulalol to that of the internal standard is not more than 1.0%.

**Containers and storage** Containers—Tight containers.

### Amoxapine

アンモキサピン

\( C_{17}H_{16}ClN_{3}O: 313.78 \)
2-Chloro-11-(piperazin-1-yl)dibenzo[f][1,4]oxazepine [14028-44-3]

Amoxapine, when dried, contains not less than 98.5% of \( C_{17}H_{16}ClN_{3}O \).

**Description** Amoxapine occurs as white to light yellowish white crystals or crystalline powder.

It is freely soluble in acetic acid (100), slightly soluble in ethanol (95) and in diethyl ether, and practically insoluble in water.

**Identification** (1) Determine the absorption spectrum of a solution of Amoxapine in 0.1 mol/L hydrochloric acid TS (1 in 50,000) as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption as the same wavelengths.

(2) Determine the infrared absorption spectrum of Amoxapine, previously dried, as directed in the potassium bromide disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) Perform the test with Amoxapine as directed under Flame Coloration Test <1.04> (2): a green color appears.

**Melting point** <2.60> 178 – 182°C

**Purity** (1) Heavy metals <1.07>—Proceed with 2.0 g of Amoxapine according to Method 2, and perform the test. Prepare the control solution with 3.0 mL of Standard Lead Solution (not more than 15 ppm).

(2) Related substances—Dissolve 0.5 g of Amoxapine in 10 mL of a mixture of ethanol (95) and acetic acid (100) (9:1), and use this solution as the sample solution. Pipet 1 mL of the sample solution, and add a mixture of ethanol (95) and acetic acid (100) (9:1) to make exactly 10 mL. Pipet 1 mL of this solution, add a mixture of ethanol (95) and acetic acid (100) (9:1) to make exactly 20 mL, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 5 \( \mu \)L each of the sample solution and standard solution on a plate of silica gel with fluorescent indicator for thin-layer chromatography. Develop the plate with a mixture of ethanol (95) and acetic acid (100) (9:1) to a distance of about 10 cm, and air-dry the plate. Examine under ultraviolet light (main wavelength: 254 nm): the spots other than the principal spot from the sample solution are not more intense than the spot from the standard solution.

**Loss on drying** <2.41> Not more than 0.4% (1 g, in vacuum, 60°C, 3 hours).

**Residue on ignition** <2.44> Not more than 0.1% (1 g).

**Assay** Weigh accurately about 0.3 g of Amoxapine, previously dried, dissolve in 50 mL of acetic acid (100), and titrate <2.50> with 0.1 mol/L perchloric acid VS until the color of the solution changes from purple through blue to greenish blue (indicator: 2 drops of crystal violet TS). Perform a blank determination, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 15.69 mg of \( C_{17}H_{16}ClN_{3}O \)

**Containers and storage** Containers—Tight containers.
Amoxicillin Hydrate

アモキシシリン水和物

\[
\text{C}_{16}\text{H}_{19}\text{N}_{3}\text{O}_{5}\text{S}.3\text{H}_{2}\text{O}: 419.45 \\
(2S,5R,6R)-6-[(2R)-2-Amino-2-(4-hydroxyphenyl)acetamino]-3,3-dimethyl-7-oxo-4-thia-1-
azabicyclo[3.2.0]heptane-2-carboxylic acid trihydrate [61336-70-7]
\]

Amoxicillin Hydrate contains not less than 950 \( \mu g \) (potency) and not more than 1010 \( \mu g \) (potency) per mg, calculated on the anhydrous basis. The potency of Amoxicillin Hydrate is expressed as mass (potency) of amoxicillin \( (\text{C}_{16}\text{H}_{19}\text{N}_{3}\text{O}_{5}\text{S}) \): 365.40.

**Description** Amoxicillin Hydrate occurs as white to light yellowish white, crystals or crystalline powder.

It is slightly soluble in water and in methanol, and very slightly soluble in ethanol (95).

**Identification** Determine the infrared absorption spectrum of Amoxicillin Hydrate as directed in the potassium bromide disk method under Infrared Spectrophotometry \(<2.25\rangle\), and compare the spectrum with the Reference Spectrum or the spectrum of Amoxicillin RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Optical rotation** \(<2.49\rangle \ [\alpha]_{D}^{20} + 290 \pm 315^\circ \ (0.1 \ g \ calculated \ on \ the \ anhydrous \ basis, \ water, \ 100 \ mL, \ 100 \ mm).

**Purity** (1) Heavy metals \(<1.07\rangle\)—To 1.0 g of Amoxicillin Hydrate add 2 mL of a solution of magnesium sulfate heptahydrate (1 in 4), mix, and heat on a water bath to dryness. Carbonize the residue by gently heating. After cooling, add 1 mL of sulfuric acid, heat carefully, then heat at 500 – 600°C to incinerate. After cooling, add 1 mL of hydrochloric acid to the residue, and heat on a water bath to dryness. Then add 10 mL of water to the residue, and heat on a water bath to dissolve. After cooling, add ammonia TS to adjust the \( \text{pH} \) to 3 – 4, and add 2 mL of dilute acetic acid. If necessary, filter, wash the residue on the filter with 10 mL of water, transfer the filtrate and washings into a Nessler tube, add water to make 50 mL, and use this solution as the test solution. Prepare the control solution as follows: To 2.0 mL of Standard Lead Solution add 2 mL of a solution of magnesium sulfate heptahydrate (1 in 4), then proceed in the same manner as for preparation of the test solution (not more than 20 ppm).

(2) Arsenic \(<1.11\rangle\)—Prepare the test solution with 1.0 g of Amoxicillin Hydrate according to Method 4, and perform the test (not more than 2 ppm).

(3) Related substances—Dissolve 0.10 g of Amoxicillin Hydrate in 50 mL of a solution of boric acid (1 in 200), and use this solution as the sample solution. Pipet 1 mL of the sample solution, add a solution of boric acid (1 in 200) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01\rangle\) according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the area of each peak other than amoxicillin obtained from the sample solution is not larger than the peak area of amoxicillin from the standard solution.

**Operating conditions**—

**Detector**—An ultraviolet absorption photometer (wavelength: 254 nm).

**Column**—A stainless steel column 4 mm in inside diameter and 30 cm in length, packed with octadecylsilylized silica gel for liquid chromatography (10 \( \mu \)m in particle diameter).

**Column temperature**—A constant temperature of about 25°C.

**Mobile phase**—Dissolve 1.36 g of sodium acetate trihydrate in 750 mL of water, adjust the \( \text{pH} \) to 4.5 with acetic acid (31), and add water to make 1000 mL. To 950 mL of this solution add 50 mL of methanol.

**Flow rate**—Adjust the flow rate so that the retention time of amoxicillin is about 8 minutes.

**Time span of measurement**—About 4 times as long as the retention time of amoxicillin.

**System suitability**—

Test for required detection: To exactly 1 mL of the standard solution add a solution of boric acid (1 in 200) to make exactly 10 mL. Confirm that the peak area of amoxicillin obtained from 10 \( \mu L \) of this solution is equivalent to 7 to 13% of that from 10 \( \mu L \) of the standard solution.

**System performance**: When the procedure is run with 10 \( \mu L \) of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amoxicillin are not less than 2500 and not more than 1.5, respectively.

**System repeatability**: When the test is repeated 6 times with 10 \( \mu L \) of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amoxicillin is not more than 1.0%.

**Water** \(<2.48\rangle\) Not less than 11.0% and not more than 15.0% (0.1 g, volumetric titration, direct titration).

**Assay** Weigh accurately an amount of Amoxicillin Hydrate and Amoxicillin RS, equivalent to about 30 mg (potency), dissolve each in a solution of boric acid (1 in 200) to make exactly 100 mL, and use these solutions as the sample solution and standard solution. Perform the test with exactly 10 \( \mu L \) each of the sample solution and standard solution as directed under Liquid Chromatography \(<2.01\rangle\) according to the following conditions, and calculate the peak areas, \( A_T \) and \( A_S \), of amoxicillin of each solution.

**Amount** (\( \mu g \) (potency)) of amoxicillin (\( \text{C}_{16}\text{H}_{19}\text{N}_{3}\text{O}_{5}\text{S} \))

\[
M_S = M_5 \times A_T/A_S \times 1000 \\
M_5: \text{Amount [mg (potency)] of Amoxicillin RS}
\]

**Operating conditions**—

**Detector**—An ultraviolet absorption photometer (wavelength: 230 nm).

**Column**—A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilylized silica gel for liquid chromatography (5 \( \mu \)m in particle diameter).

**Column temperature**—A constant temperature of about 25°C.
Mobile phase: Dissolve 1.361 g of sodium acetate trihydrate in 750 mL of water, adjust the pH to 4.5 with acetic acid (31), and add water to make 1000 mL. To 950 mL of this solution add 50 mL of methanol.

Flow rate: Adjust the flow rate so that the retention time of amoxicillin is about 8 minutes.

System suitability—

System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates of the peak of amoxicillin is not less than 2500.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amoxicillin is not more than 1.0%.

Containers and storage—Containers—Tight containers.

### Amoxicillin Capsules

アモキシリンカプセル

Amoxicillin Capsules contain not less than 92.0% and not more than 105.0% of the labeled potency of Amoxicillin (C₁₆H₁₉N₃O₅S: 365.40).

Method of preparation—Prepare as directed under Capsules, with Amoxicillin Hydrate.

Identification—Take out the contents of Amoxicillin Capsules, to a quantity of the contents, equivalent to 8 mg (potency) of Amoxicillin Hydrate according to the labeled amount, add 2 mL of 0.01 mol/L hydrochloric acid TS, shake for 30 minutes, filter, and use the filtrate as the sample solution. Separately, dissolve an amount equivalent to 8 mg (potency) of Amoxicillin RS in 2 mL of 0.01 mol/L hydrochloric acid TS, and use this solution as the standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.03>. Spot 5 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of tetrahydrofuran, water and formic acid (50:5:2) to a distance of about 10 cm, and air-dry the plate. Spray evenly a solution of ninhydrin in ethanol (95) (1 in 20) on the plate, and heat the plate at 110°C for 15 minutes: the principal spot obtained from the sample solution and the standard solution show a red-purple color and the same Rf value.

Purity—Related substances—Take out the contents of Amoxicillin Capsules, to a quantity of the contents, equivalent to 0.1 g (potency) of Amoxicillin Hydrate according to the labeled amount, add 30 mL of a solution of boric acid (1 in 200), shake for 15 minutes, and add a solution of boric acid (1 in 200) to make 50 mL. Centrifuge this solution, and use the supernatant liquid as the sample solution. Pipet 1 mL of the sample solution, add a solution of boric acid (1 in 200) to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the area of each peak other than amoxicillin obtained from the sample solution is not larger than the peak area of amoxicillin from the standard solution.

Operating conditions—

Proceed as directed in the operating conditions in the Purity (3) under Amoxicillin Hydrate.

System suitability—

Test for required detectability and system repeatability: Proceed as directed in the system suitability in the Purity (3) under Amoxicillin Hydrate.

System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amoxicillin is not less than 2500 and not more than 1.5, respectively.

Water <2.48> Not more than 15.0% (0.1 g, volumetric titration, direct titration).

Uniformity of dosage units <6.02> It meets the requirements of the Mass variation test.

Dissolution <6.10> When the test is performed at 100 revolutions per minute according to the Paddle method using the sinker, using 900 mL of water as the dissolution medium, the dissolution rate in 60 minutes of Amoxicillin Capsules is not less than 75%.

Start the test with 1 capsule of Amoxicillin Capsules, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.45 μm. Discard the first 10 mL of the filtrate, pipet V mL of the subsequent filtrate, add water to make exactly V mL so that each mL contains about 56 μg (potency) of Amoxicillin Hydrate according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately an amount equivalent to about 28 mg (potency) of Amoxicillin RS, dissolve in water to make exactly 100 mL. Pipet 5 mL of this solution, add water to make exactly 25 mL, and use this solution as the standard solution. Perform the test with exactly 50 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.07> according to the following conditions, and determine the peak areas, A₁ and A₅, of amoxicillin in each solution.

Dissolution rate (% with respect to the labeled amount of amoxicillin (C₁₆H₁₉N₃O₅S) = Mₛ × A₁/₅ × V/V × 1/C × 180

Mₛ: Amount [mg (potency)] of Amoxicillin RS C: Labeled amount [mg (potency)] of amoxicillin (C₁₆H₁₉N₃O₅S) in 1 capsule

Operating conditions—

Proceed as directed in the operating conditions in the Assay under Amoxicillin Hydrate.

System suitability—

System performance: When the procedure is run with 50 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amoxicillin are not less than 2500 and not more than 2.0, respectively.

System repeatability: When the test is repeated 6 times with 50 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of amoxicillin is not more than 1.5%.
Amphotericin B

Assay Weigh accurately the mass of not less than 10 Amoxicillin Capsules, take out the contents, and weigh accurately the mass of the emptied shells. Weigh accurately an amount equivalent to about 0.1 g (potency) of Amoxicillin Hydrate, add 70 mL of water, shake for 15 minutes, and add water to make exactly 100 mL. Centrifuge this solution, and use the supernatant liquid as the sample solution. Separately, weigh accurately an amount equivalent to about 20 mg (potency) of Amoxicillin RS, dissolve in water to make exactly 20 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography <2.01> according to the following conditions, and determine the peak areas, $A_T$ and $A_S$, of amoxicillin in each solution.

Amount [mg (potency)] of amoxicillin (C₁₆H₁₉N₃O₅S)  
= $M_S \times \frac{A_T}{A_S} \times 5$

$M_S$: Amount [mg (potency)] of Amoxicillin RS

Operating conditions—

Column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay under Amoxicillin Hydrate.

Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4 mm in inside diameter and 30 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (10 μm in particle diameter).

System suitability—

System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of amoxicillin are not less than 2500 and not more than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of peak areas of amoxicillin is not more than 1.0%.

Containers and storage Containers—Tight containers.

Amphotericin B is a polyene macrolide substance having antifungal activity produced by the growth of Streptomyces nodosus.

It contains not less than 840 μg (potency) per mg, calculated on the dried basis. The potency of Amphotericin B is expressed as mass (potency) of amphotericin B (C₄₇H₇₃NO₁₇).

Description Amphotericin B occurs as a yellow to orange powder.

It is freely soluble in dimethylsulfoxide and practically insoluble in water and in ethanol (95).

Identification (1) Dissolve 5 mg of Amphotericin B in 10 mL of dimethylsulfoxide. To 1 mL of this solution add 5 mL of phosphoric acid: a blue color develops between the two layers, and the solution becomes blue by shaking. After addition of 15 mL of water it becomes yellow to light yellow-brown by shaking.

(2) Dissolve 25 mg of Amphotericin B in 5 mL of dimethylsulfoxide, and add methanol to make 50 mL. To 1 mL of this solution add methanol to make 50 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum or the spectrum of Amphotericin B RS: both spectra exhibit similar intensities of absorption at the same wavelengths.

Purity Amphotericin A—Weigh accurately about 50 mg each of Amphotericin B and Amphotericin B RS, add exactly 10 mL each of dimethylsulfoxide to dissolve, and add methanol to make exactly 50 mL. Pipet 4 mL each of these solutions, add methanol to make exactly 50 mL, and use these solutions as the sample solution and standard solution (1), respectively. Separately, weigh accurately about 20 mg of Nystatin RS, add exactly 40 mL of dimethylsulfoxide to dissolve, then add methanol to make exactly 200 mL. Pipet 4 mL of this solution, add methanol to make exactly 50 mL, and use this solution as the standard solution (2). Perform
the test with these solutions as directed under Ultraviolet-visible Spectrophotometry <2.24> using a solution obtained in the same manner as the sample solution as the blank, and determine the absorbances at 282 nm and at 304 nm. Calculate the amount of amphotericin A by the following equation: not more than 5% for Amphotericin B used for injections, and not more than 15% for Amphotericin B not used for injections.

\[
\text{Amount (\%)} = \frac{M_S \times ([A_{S1}] \times [A_{T1}] - [A_{S2}] \times [A_{T1}]) \times 25}{M_T \times ([A_{S1}] \times [A_{S2}] - [A_{S2}] \times [A_{S2}])}
\]

- \(M_S\): Amount (mg) of Nystatin RS
- \(M_T\): Amount (mg) of the sample
- \(A_{S1}\): Absorbance at 282 nm of the standard solution (1)
- \(A_{S2}\): Absorbance at 282 nm of the standard solution (2)
- \(A_{T1}\): Absorbance at 304 nm of the sample solution
- \(A_{T2}\): Absorbance at 304 nm of the sample solution

Loss on drying <2.41> Not more than 5.0% (0.1 g, in vacuum, 60°C, 3 hours).

**Assay** Perform the test according to the Cylinder-plate method as directed under Microbial Assay for Antibiotics <4.02> according to the following conditions.

(i) Test organism—Saccharomyces cerevisiae ATCC 9763

(ii) Culture medium—Use the medium 2) under (1) Agar media for seed and base layer.

(iii) Preparation of cylinder-agar plate—Proceed as directed in 1.5 under the Cylinder plate method, using Petri dish plates not dispensing the agar medium for base layer and dispensing 8.0 mL of the seeded agar medium.

(iv) Standard solution—Use light-resistant vessels. Weigh accurately an amount of Amphotericin B RS equivalent to about 20 mg (potency), dissolve in dimethylsulfoxide to make exactly 20 mL, and use this solution as the standard stock solution. Keep the standard stock solution at 5°C or below and use within 24 hours. Take exactly a suitable amount of the standard stock solution before use, and add dimethylsulfoxide to make solutions so that each mL contains 200 \(\mu\)g (potency) and 50 \(\mu\)g (potency). Pipet 1 mL each of these solutions, add 0.2 mol/L phosphate buffer solution, pH 10.5 to make exactly 20 mL, and use these solutions as the high concentration standard solution and low concentration standard solution, respectively.

(v) Sample solution—Use light-resistant vessels. Weigh accurately an amount of Amphotericin B equivalent to about 20 mg (potency), dissolve in dimethylsulfoxide to make exactly 20 mL, and use this solution as the sample solution. Take exactly a suitable amount of the sample stock solution, add dimethylsulfoxide to make solutions so that each mL contains 200 \(\mu\)g (potency) and 50 \(\mu\)g (potency). Pipet 1 mL each of these solutions, add 0.2 mol/L phosphate buffer solution, pH 10.5 to make exactly 20 mL, and use these solutions as the high concentration sample solution and low concentration sample solution, respectively.

**Containers and storage** Containers—Tight containers.

Storage—Light-resistant, and in a cold place.

**Amphotericin B for Injection**

注射用アムホテリシン B

Amphotericin B for Injection is a preparation for injection which is dissolved before use.

It contains not less than 90.0% and not more than 120.0% of the labeled amount of amphotericin B (C_{47}H_{73}NO_{17}: 924.08).

**Method of preparation** Prepare as directed under Injections, with Amphotericin B.

**Description** Amphotericin B for Injection occurs as yellow to orange, powder or masses.

**Identification** To an amount of Amphotericin B for Injection, equivalent to 25 mg (potency) of Amphotericin B according to the labeled amount, add 5 mL of dimethylsulfoxide and 45 mL of methanol, and shake. To 1 mL of this solution add methanol to make 50 mL, and filter if necessary. Determine the absorption spectrum of the solution as directed under Ultraviolet-visible Spectrophotometry <2.24> it exhibits maxima between 361 nm and 365 nm, between 380 nm and 384 nm and between 403 nm and 407 nm.

**pH** <2.45> Dissolve an amount of Amphotericin B for Injection, equivalent to 50 mg (potency) of Amphotericin B according to the labeled amount, in 10 mL of water. To 1 mL of this solution add water to make 50 mL: 7.2 – 8.0.

**Purity** Clarity and color of solution—Dissolve an amount of Amphotericin B for Injection, equivalent to 50 mg (potency) of Amphotericin B according to the labeled amount, in 10 mL of water: the solution is clear and yellow to orange.

**Loss on drying** <2.41> Not more than 8.0% (0.3 g, in vacuum, 60°C, 3 hours).

**Bacterial endotoxins** <4.01> Less than 3.0 EU/mg (potency).

**Uniformity of dosage units** <6.02> It meets the requirements of the Mass variation test. However, use the average of the limits specified in the potency definition for \(T\).

**Foreign insoluble matter** <6.06> Perform the test according to Method 2: it meets the requirement.

**Insoluble particulate matter** <6.07> Perform the test according to Method 1: it meets the requirement.

**Sterility** <4.06> Perform the test according to the Membrane filtration method: it meets the requirement.

**Assay** Perform the test according to the Cylinder-plate method as directed under Microbial Assay for Antibiotics <4.02> according to the following conditions.

(i) Test organism, culture medium, preparation of cylinder-agar plate and standard solutions—Proceed as directed in the Assay under Amphotericin B.

(ii) Sample solutions—Prepare using light-resistant containers. Weigh accurately an amount of Amphotericin B for Injection, equivalent to about 50 mg (potency) according to the labeled amount, dissolve in dimethylsulfoxide to make exactly 50 mL, and use this solution as the sample stock solution. Measure exactly a suitable quantity of the sample
Amphotericin B Syrup

アムホテリシン B シロップ

Amphotericin B Syrup contain not less than 90.0% and not more than 115.0% of the labeled amount of amphotericin B (C_{47}H_{73}NO_{17}; 924.08).

Method of preparation  Prepare as directed under Syrup, with Amphotericin B.

Identification  To an amount of Amphotericin B Syrup, equivalent to 25 mg (potency) of Amphotericin B according to the labeled amount, add 5 mL of dimethylsulfoxide and 45 mL of methanol, and shake. To 1 mL of this solution add methanol to make 50 mL, and filter, if necessary. Determine the absorption spectrum of the solution as directed under Ultraviolet-visible Spectrophotometry (2.24): it exhibits maxima between 361 nm and 365 nm, between 380 nm and 384 nm and between 403 nm and 407 nm.

pH 〈2.54〉  5.0 – 7.0

Microbial limit 〈4.05〉  The acceptance criteria of TAMC and TYMC are 10^5 CFU/mL and 5 × 10^5 CFU/mL, respectively.

Assay  Perform the test according to the Cylinder-plate method as directed under Microbial Assay for Antibiotics (4.02) according to the following conditions.

(i)  Test organism, culture medium, preparation of cylinder-agar plate and standard solutions—Proceed as directed in the Assay under Amphotericin B.

(ii) Sample solutions—Prepare using light-resistant containers. Weigh accurately an amount of Amphotericin B Syrup, equivalent to about 0.1 g (potency) according to the labeled amount, add about 70 mL of dimethylsulfoxide, shake, then add dimethylsulfoxide to make exactly 100 mL, and use this solution as the sample stock solution. Measure exactly a suitable amount of the sample stock solution, add dimethylsulfoxide to make solutions so that each mL contains about 200 μg (potency) and 50 μg (potency). Pipet 1 mL of each of these solutions, add 0.2 mol/L phosphate buffer solution, pH 10.5 to make exactly 20 mL, and use these solutions as the high concentration sample solution and low concentration sample solution, respectively.

Containers and storage  Containers—Light-resistant, at a cold place.

Amphotericin B Tablets

アムホテリシン B 錠

Amphotericin B Tablets contain not less than 90.0% and not more than 120.0% of the labeled amount of amphotericin B (C_{47}H_{73}NO_{17}; 924.08).

Method of preparation  Prepare as directed under Tablets, with Amphotericin B.

Identification  To an amount of pulverized Amphotericin B Tablets, equivalent to 25 mg (potency) of Amphotericin B according to the labeled amount, add 5 mL of dimethylsulfoxide and 45 mL of methanol, and shake. To 1 mL of this solution add methanol to make 50 mL, and filter, if necessary. Determine the absorption spectrum of the solution as directed under Ultraviolet-visible Spectrophotometry (2.24): it exhibits maxima between 361 nm and 365 nm, between 380 nm and 384 nm and between 403 nm and 407 nm.

Uniformity of dosage units 〈6.02〉  It meets the requirement of the Mass variation test. However, use the average of the limits specified in the potency definition for T.

Loss on drying 〈2.41〉  Not more than 5.0% (0.3 g, in vacuum, 60°C, 3 hours).

Assay  Perform the test according to the Cylinder-plate method as directed under Microbial Assay for Antibiotics (4.02) according to the following conditions.

(i)  Test organism, culture medium, preparation of cylinder-agar plate and standard solutions—Proceed as directed in the Assay under Amphotericin B.

(ii) Sample solutions—Prepare using light-resistant containers. Weigh accurately and powder not less than 20 tablets of Amphotericin B Tablets. Weigh accurately a part of the powder, equivalent to about 0.1 g (potency) according to the labeled amount, add about 70 mL of dimethylsulfoxide, shake, then add dimethylsulfoxide to make exactly 100 mL, centrifuge, and use the supernatant liquid as the sample stock solution. Measure exactly a suitable amount of the sample stock solution, add dimethylsulfoxide to make solutions so that each mL contains 200 μg (potency) and 50 μg (potency). Pipet 1 mL each of these solutions, add 0.2 mol/L phosphate buffer solution, pH 10.5 to make exactly 20 mL, and use these solutions as the high concentration sample solution and low concentration sample solution, respectively.

Containers and storage  Containers—Well-closed containers.
Anhydrous Ampicillin

Anhydrous Aminobenzylpenicillin

無水アンピシリン

\[
\begin{align*}
\text{C}_{16}\text{H}_{19}\text{N}_3\text{O}_4\text{S} : 349.40 \\
(2S,5R,6R)-6-[(2R)-2\text{-Amino-2-phenylacetylamino}] &- \\
3,3\text{-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid} \\
[69-53-4]
\end{align*}
\]

Anhydrous Ampicillin contains not less than 960 µg (potency) and not more than 1005 µg (potency) per mg, calculated on the anhydrous basis. The potency of Anhydrous Ampicillin is expressed as mass (potency) of ampicillin (C\text{16}H\text{19}N\text{3}O\text{4}S).

**Description** Anhydrous Ampicillin occurs as white to light yellowish white, crystals or crystalline powder.

It is sparingly soluble in water, slightly soluble in methanol, very slightly soluble in ethanol (95%), and practically insoluble in acetonitrile.

**Identification** Determine the infrared absorption spectrum of Anhydrous Ampicillin as directed in the potassium bromide disk method under Infrared Spectrophotometry \(\text{\angle2.25}\), and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Optical rotation** \(\text{\angle2.45}\) \([\alpha]_D^{\text{20}} + 280 - + 305^\circ\) (0.5 g calculated on the anhydrous basis, water, 100 mL, 100 mm).

**pH** \(\text{\angle2.45}\) The pH of a solution obtained by dissolving 1.0 g of Anhydrous Ampicillin in 100 mL of water is between 4.0 and 5.5.

**Purity (1)** Heavy metals \(\text{\angle1.07}\)—Proceed with 1.0 g of Anhydrous Ampicillin according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(2) Arsenic \(\text{\angle1.11}\)—Prepare the test solution with 1.0 g of Anhydrous Ampicillin according to Method 3, and perform the test (not more than 2 ppm).

(3) Related substances—Dissolve 0.05 g of Anhydrous Ampicillin in the mobile phase to make 50 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 µL each of the sample solution and standard solution as directed under Liquid Chromatography \(\text{\angle2.01}\) according to the following conditions, and determine each peak area by the automatic integration method: the area of each peak other than ampicillin from the sample solution is not larger than the peak area of ampicillin from the standard solution.

**Operating conditions**—

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay.

Time span of measurement: As long as about 10 times of the retention time of ampicillin.

**System suitability**—

Test for required detectability: To exactly 1 mL of the standard solution add the mobile phase to make exactly 10 mL. Confirm that the peak area of ampicillin obtained from 10 µL of this solution is equivalent to 7 to 13% of that from 10 µL of the standard solution.

System performance, and system repeatability: Proceed as directed in the system suitability in the Assay.

**Water** \(\text{\angle2.45}\) Not more than 2.0% (2.5 g, volumetric titration, direct titration).

**Assay** Weigh accurately an amount of Anhydrous Ampicillin and Ampicillin RS, equivalent to about 50 mg (potency), add exactly 5 mL each of the internal standard solution and the mobile phase to make 50 mL, and use these solutions as the sample solution and standard solution. Perform the test with 10 µL each of the sample solution and standard solution as directed under Liquid Chromatography \(\text{\angle2.01}\) according to the following conditions, and calculate the ratios, \(Q_T\) and \(Q_S\), of the peak area of ampicillin to that of the internal standard.

\[
\text{Amount \([\mu g \text{ (potency)}]\) of ampicillin (C}_{16}\text{H}_{19}\text{N}_3\text{O}_4\text{S})} = \frac{M_S \times Q_T}{Q_S} \times 1000
\]

**Containers and storage** Containers—Tight containers.
Ampicillin Hydrate
Aminobenzylpenicillin Hydrate
アンピシリン水和物

Ampicillin Hydrate contains not less than 960 μg (potency) and not more than 1005 μg (potency) per mg, calculated on the anhydrous basis. The potency of Ampicillin Hydrate is expressed as mass (potency) of ampicillin (C₁₆H₁₉N₃O₄S: 349.40).

**Description** Ampicillin Hydrate occurs as a white to light yellowish white, crystals or crystalline powder.

It is sparingly soluble in water, slightly soluble in methanol, very slightly soluble in ethanol (95), and practically insoluble in acetonitrile.

**Identification** Determine the infrared absorption spectrum of Ampicillin Hydrate as directed in the potassium bromide tablet, and compare the spectrum with the Reference Spectrum or the spectrum of Ampicillin RS: both spectra exhibit similar intensities of absorption at the same wave numbers.

**Optical rotation** \[ \theta_d ^{25} + 280 - + 305^\circ \] (0.5 g calculated on the anhydrous basis, water, 100 mL, 100 mm).

**pH** \(< 2.5^\circ\) The pH of a solution obtained by dissolving 1.0 g of Ampicillin Hydrate in 400 mL of water is between 3.5 and 5.5.

**Purity**

(1) Heavy metals \(< l.0^\circ\)—Proceed with 1.0 g of Ampicillin Hydrate according to Method 2, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(2) Arsenic \(< l.1^\circ\)—Prepare the test solution with 1.0 g of Ampicillin hydrate according to Method 3, and perform the test (not more than 2 ppm).

(3) Related substances—Dissolve 50 mg of Ampicillin hydrate in the mobile phase to make 50 mL, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography \(< 2.0^\circ\) according to the following conditions, and determine each peak area by the automatic integration method: each peak area other than that of ampicillin obtained from the sample solution is not larger than the peak area of ampicillin from the standard solution.

**Operating conditions**

Detector, column, column temperature, mobile phase, and flow rate: Proceed as directed in the operating conditions in the Assay.

Time span of measurement: About 10 times as long as the retention time of ampicillin.

**System suitability**—

Test for required detectability: Measure exactly 1 mL of the standard solution, and add the mobile phase to make exactly 10 mL. Confirm that the peak area of ampicillin obtained from 10 μL of this solution is equivalent to 7 to 13% of that from 10 μL of the standard solution.

System performance, and system repeatability: Proceed as directed in the system suitability in the Assay.

(4) \( N,N \)-Dimethylaniline—Weigh accurately about 1 g of Ampicillin Hydrate, dissolve in 5 mL of sodium hydroxide TS, add exactly 1 mL of the internal standard solution, shake vigorously for 1 minute, and use the upper layer liquid obtained after allowing it to stand as the sample solution. Separately, weigh accurately about 50 mg of \( N,N \)-dimethylaniline, dissolve in 2 mL of hydrochloric acid and 20 mL of water, add water to make exactly 50 mL, and use this solution as the standard stock solution. Pipet 5 mL of the standard stock solution, and add water to make exactly 250 mL. Pipet 1 mL of this solution, add 5 mL of sodium hydroxide TS and exactly 1 mL of the internal standard solution, shake vigorously for 1 minute, and use the upper layer liquid obtained after allowing it to stand as the standard solution. Perform the test with 1 μL each of the sample solution and standard solution as directed under Gas Chromatography \(< 2.0^\circ\) according to the following conditions, calculate the ratios, \( Q_1 \) and \( Q_2 \), of the peak area of \( N,N \)-dimethylaniline to that of the internal standard, and calculate the amount of \( N,N \)-dimethylaniline by the following equation: not more than 20 ppm.

\[
\text{Amount (ppm) of } N,N\text{-dimethylaniline} = \frac{M_z}{M_t} \times \frac{Q_1}{Q_2} \times 400
\]

\( M_z \): Amount (g) of \( N,N \)-dimethylaniline

\( M_t \): Amount (g) of the sample

**Internal standard solution**—A solution of naphthalene in cyclohexane (1 in 20,000).

**Operating conditions**—

Detector: A hydrogen flame-ionization detector.

Column: A glass column 2.6 mm in inside diameter and 2 m in length, packed with silicic earth for gas chromatography (180–250 μm in particle diameter) coated with 50% phenyl-50% methyl polysiloxane for gas chromatography at the ratio of 3%.

Column temperature: A constant temperature of about 120°C.

Carrier gas: Helium

Flow rate: Adjust the flow rate so that the retention time of \( N,N \)-dimethylaniline is about 5 minutes.

**System suitability**—

Test for required detectability: Measure exactly 1 mL of the standard stock solution, and add water to make exactly 250 mL. Pipet 1 mL of this solution, add 5 mL of sodium hydroxide TS and exactly 1 mL of the internal standard solution, shake vigorously for 1 minute, and use the upper layer liquid obtained after allowing it to stand for the test. Confirm that when the procedure is run with 1 μL of the upper layer liquid under the above operating conditions, the ratio of the peak area of \( N,N \)-dimethylaniline to that of the inter-
Ampicillin Sodium

Aminobenzylpenicillin Sodium

アンピシリンナトリウム

\[
\text{C}_{16}\text{H}_{18}\text{N}_{3}\text{NaO}_{4}\text{S} : 371.39 \\
\text{Monosodium (2S,5R,6R)-6-[(2R)-2-amino-2-phenylacetylaminol]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylate [69-52-3]}
\]

Ampicillin Sodium contains not less than 850 μg (potency) and not more than 950 μg (potency) per mg, calculated on the anhydrous basis. The potency of Ampicillin Sodium is expressed as mass (potency) of ampicillin (\(\text{C}_{16}\text{H}_{18}\text{N}_{3}\text{O}_{4}\text{S} : 349.40\)).

**Description**

Ampicillin Sodium occurs as white to light yellowish white, crystals or crystalline powder.

It is very soluble in water, and sparingly soluble in ethanol (99.5).

**Identification (1)**

Determine the infrared absorption spectrum of Ampicillin Sodium, previously dried in a desiccator (reduced pressure not exceeding 0.67 kPa, 60°C) for 3 hours, as directed in the potassium bromide disk method under Infrared Spectrophotometry (2.01) according to the following conditions, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(2) Ampicillin Sodium responds to the Qualitative Tests (1.09) (1) for sodium salt.

**Optical rotation**

\[ \alpha^\circ = +246 - +272^\circ \text{ (1 g calculated on the anhydrous basis, water, 100 mL, 100 mm).} \]

**pH**

The pH of a solution obtained by dissolving 1.0 g of Ampicillin Sodium in 10 mL of water is between 8.0 and 10.0.

**Purity (1)**

Clarity and color of solution—Dissolve 1.0 g of Ampicillin Sodium in 10 mL of water: the solution is clear and colorless or pale yellow.

(2) Heavy metals \(<1.07\) —Proceed with 1.0 g of Ampicillin Sodium according to Method 1, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(3) Arsenic \(<1.17\) —Prepare the test solution with 1.0 g of Ampicillin Sodium according to Method 1, and perform the test (not more than 2 ppm).

(4) Related substances—Dissolve 50 mg of Ampicillin Sodium in 50 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography (2.01) according to the following conditions, and determine each peak area by the automatic integration method: the peak...
Ampicillin Sodium for Injection

Ampicillin Sodium for Injection is a preparation for injection which is dissolved before use.

It contains not less than 90.0% and not more than 110.0% of the labeled amount of ampicillin (C_{16}H_{19}N_{3}O_{4}S: 349.40).

Method of preparation
Prepare as directed under Injections, with Ampicillin Sodium.

Description
Ampicillin Sodium for Injection occurs as white to light yellowish white crystals or crystalline powder.

Identification
Proceed as directed in the Identification (1) under Ampicillin Sodium.

Osmotic pressure ratio
Being specified separately.

pH
The pH of a solution prepared by dissolving an amount of Ampicillin Sodium for Injection, equivalent to 1.0 g (potency) of Ampicillin Sodium according to the labeled amount, in 10 mL of water is 8.0 to 10.0.

Purity
Clarity and color of solution—Dissolve an amount of Ampicillin Sodium for Injection, equivalent to 0.25 g (potency) of Ampicillin Sodium according to the labeled amount, in 0.75 mL of water: the solution is clear. Perform the test with the solution as directed under Ultraviolet-visible Spectrophotometry <2.24>:
the absorbance at 400 nm is not more than 0.40.

Water
Not more than 2.0% (0.2 g, volumetric titration, direct titration).

Bacterial endotoxins
Less than 0.075 EU/mg (potency).

Uniformity of dosage units
It meets the requirement of the Mass variation test.

Foreign insoluble matter
Perform the test according to Method 2: it meets the requirement.

Insoluble particulate matter
It meets the requirement.

Assay
Weigh accurately the mass of the contents of not less than 10 containers of Ampicillin Sodium for Injection. Weigh accurately an amount of the contents, equivalent to about 50 mg (potency) of Ampicillin Sodium, dissolve in 5 mL of the internal standard solution, and use this solution as the sample solution.

Sterility
Perform the test according to the Membrane filtration method: it meets the requirement.
Amyl Nitrite

C₅H₁₁NO₂: 117.15

Amyl Nitrite is the nitrous acid ester of 3-methylbutanol-1 and contains a small quantity of 2-methylbutanol-1 and the nitrous acid esters of other homologues.

It contains not less than 90.0% of C₅H₁₁NO₂.

Description Amyl Nitrite is a clear, light yellowish liquid, and has a characteristic, fruity odor.

It is miscible with ethanol (95), and with diethyl ether. It is practically insoluble in water. It is affected by light and by heat.

It is volatile at ordinary temperature and flammable even at a low temperature.

Boiling point: about 97°C

Identification Determine the infrared spectrum of Amyl Nitrite as directed in the liquid film method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

Specific gravity <2.56> d₅₀: 0.871 - 0.880

Purity (1) Acidity—To 5 mL of Amyl Nitrite add a mixture of 1.0 mL of 1 mol/L sodium hydroxide VS, 10 mL of water and 1 drop of phenolphthalein TS, shake, and allow to stand for 1 minute: the light red color of the water layer does not disappear.

(2) Water—Allow 2.0 mL of Amyl Nitrite to stand in ice water: no turbidity is produced.

(3) Aldehyde—To 3 mL of a mixture of equal volumes of silver nitrate TS and aldehyde free-ethanol add ammonia TS dropwise until the precipitate first formed is redissolved. Add 1.0 mL of Amyl Nitrite, and warm between 60°C and 70°C for 1 minute: a brown to black color is not produced.

(4) Residue on evaporation—Evaporate 10.0 mL of Amyl Nitrite on a water bath in a draft, carefully protecting from flame, and dry the residue at 105°C for 1 hour: the mass of the residue is not more than 1.0 mg.

Assay Weigh accurately a volumetric flask containing 10 mL of ethanol (95), add about 0.5 g of Amyl Nitrite, and weigh accurately again. Add exactly 25 mL of 0.1 mol/L silver nitrate VS, then add 15 mL of potassium chlorate solution (1 in 20) and 10 mL of dilute nitric acid, stopper the flask immediately, and shake it vigorously for 5 minutes. Dilute with water to make exactly 100 mL, shake, and filter through dry filter paper. Discard the first 20 mL of the filtrate, measure exactly 50 mL of the subsequent filtrate, and titrate <2.50> the excess silver nitrate with 0.1 mol/L ammonium thiocyanate VS (indicator: 2 mL of ammonium iron (III) sulfate TS). Perform a blank determination.

Each mL of 0.1 mol/L silver nitrate VS = 35.15 mg of C₅H₁₁NO₂

Containers and storage Containers—Hermetic containers. Not exceeding 10–ml capacity.

Storage—Light-resistant, in a cold place, and remote from fire.

Dental Antiformin

Dental Sodium Hypochlorite Solution

Dental Antiformin contains not less than 3.0 w/v% and not more than 6.0 w/v% of sodium hypochlorite (NaClO: 74.44).

Description Dental Antiformin is a slightly light yellow-green, clear liquid. It has a slight odor of chlorine.

It gradually changes by light.

Identification (1) Dental Antiformin changes red litmus paper to blue, and then decolorizes it.

(2) To Dental Antiformin add dilute hydrochloric acid: it evolves the odor of chlorine, and the gas changes potassium iodide starch paper moistened with water to blue.
Antipyrine / Official Monographs

(3) Dental Antiformin responds to the Qualitative Tests <1.09> (1) for sodium salt.

Assay Measure exactly 3 mL of Dental Antiformin in a glass-stoppered flask, add 50 mL of water, 2 g of potassium iodide and 10 mL of acetic acid (3L), and titrate <2.50> the liberated iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 3 mL of starch TS).

Each mL of 0.1 mol/L sodium thiosulfate VS = 3.722 mg of NaClO

Containers and storage Containers—Tight containers.

Storage—Light-resistant, and not exceeding 10°C.

Antipyrine

Phenazone

アンチピリン

C₁₁H₁₂N₂O: 188.23
1,5-Dimethyl-2-phenyl-1,2-dihydro-3H-pyrazol-3-one [60-80-0]

Antipyrine, when dried, contains not less than 99.0% of C₁₁H₁₂N₂O.

Description Antipyrine occurs as colorless or white crystals, or a white, crystalline powder. It is odorless, and has a slightly bitter taste.

It is very soluble in water, freely soluble in ethanol (95), and sparingly soluble in diethyl ether.

A solution of Antipyrine (1 in 10) is neutral.

Identification (1) To 5 mL of a solution of Antipyrine (1 in 100) add 2 drops of sodium nitrite TS and 1 mL of dilute sulfuric acid: a deep green color develops.

(2) To 2 mL of a solution of Antipyrine (1 in 100) add 4 drops of dilute iron (III) chloride TS: a yellow-red color develops. Then add 10 drops of dilute sulfuric acid: the color changes to light yellow.

(3) To 5 mL of a solution of Antipyrine (1 in 100) add 2 to 3 drops of tannic acid TS: a white precipitate is produced.

(4) To 0.1 g of Antipyrine add 0.1 g of vanillin, 5 mL of water and 2 mL of sulfuric acid, boil the mixture, and cool: a yellow-red precipitate is produced.

Melting point <2.60> 111 – 113°C

Purity (1) Chloride <1.07>—Perform the test with 1.0 g of Antipyrine. Prepare the control solution with 0.40 mL of 0.01 mol/L hydrochloric acid VS (not more than 0.014%).

(2) Heavy metals <1.07>—Proceed with 1.0 g of Antipyrine according to Method 1, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 20 ppm).

(3) Readily carbonizable substances<1.15>—Perform the test with 0.5 g of Antipyrine: the solution remains colorless.

Loss on drying <2.41> Not more than 0.5% (1 g, silica gel, 4 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Dissolve about 0.2 g of Antipyrine, previously dried and accurately weighed, in 20 mL of sodium acetate TS, add exactly 30 mL of 0.05 mol/L iodine VS, and allow to stand for 20 minutes with occasional shaking. Dissolve the precipitate in 10 mL of chloroform, and titrate <2.50> the excess iodine with 0.1 mol/L sodium thiosulfate VS (indicator: 3 mL of starch TS). Perform a blank determination.

Each mL of 0.05 mol/L iodine VS = 9.412 mg of C₁₁H₁₂N₂O

Containers and storage Containers—Well-closed containers.

Aprindine Hydrochloride

アプリンジン塩酸塩

C₂₂H₃₈N₂.HCl: 358.95
N-(2,3-Dihydro-1H-inden-2-yl)-N',N'-diethyl-N-phenylpropane-1,3-diamine monohydrochloride [33237-74-0]

Aprindine Hydrochloride, when dried, contains not less than 98.5% and not more than 101.0% of C₂₂H₃₈N₂.HCl.

Description Aprindine Hydrochloride occurs as a white to pale yellowish white crystalline powder. It has a bitter taste, numbing the tongue.

It is very soluble in water, in methanol and in acetic acid (100), and freely soluble in ethanol (99.5).

It gradually turns brown on exposure to light.

Identification (1) Dissolve 10 mg of Aprindine Hydrochloride in a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125) to make 50 mL. Determine the absorption spectrum of this solution as directed under Ultraviolet-visible Spectrophotometry <2.24>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wavelengths.

(2) Determine the infrared absorption spectrum of Aprindine Hydrochloride as directed in the potassium chloride disk method under Infrared Spectrophotometry <2.25>, and compare the spectrum with the Reference Spectrum: both spectra exhibit similar intensities of absorption at the same wave numbers.

(3) To 5 mL of a solution of Aprindine Hydrochloride (1 in 50) add 1 mL of dilute nitric acid: this solution responds to the Qualitative Tests <1.09> for chloride.

pH <2.54> Dissolve 1.0 g of Aprindine Hydrochloride in 50 mL of water: the pH of the solution is between 6.4 and 7.0.

Melting point <2.60> 127 – 131°C.
Purity (1) Clarity and color of solution—Dissolve 1.0 g of Aprindine Hydrochloride in 10 mL of methanol: the solution is clear, and its absorbance at 420 nm determined as directed under Ultraviolet-visible Spectrophotometry is not more than 0.10.

(2) Heavy metals. Proceed with 1.0 g of Aprindine Hydrochloride in the same manner, and make any necessary correction.

(3) Related substances. Dissolve 25 mg of Aprindine Hydrochloride in 10 mL of the mobile phase, and use this solution as the sample solution. Pipet 1 mL of the sample solution, add the mobile phase to make exactly 100 mL, and use this solution as the standard solution. Perform the test with exactly 10 μL each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions. Determine each peak area of both solutions by the automatic integration method: the area of the peak other than aprindine obtained from the sample solution is not larger than 1/10 times the peak area of aprindine from the standard solution.

Operating conditions—
Detector: An ultraviolet absorption photometer (wavelength: 254 nm).
Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Mobile phase: Dissolve 3.40 g of potassium dihydrogen phosphate in 500 mL of water, and adjust the pH to 3.0 with hydrochloric acid. To 500 mL of this solution add 500 mL of acetonitrile.
Flow rate: Adjust the flow rate so that the retention time of aprindine is about 6 minutes.
Time span of measurement: About 4 times as long as the retention time of aprindine.
System suitability—
Test for required detectability: Pipet 1 mL of the standard solution, and add the mobile phase to make exactly 10 mL. Confirm that the peak area of aprindine obtained from 10 μL of this solution is equivalent to 7 to 13% of that from 10 μL of the standard solution.
System performance: When the procedure is run with 10 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of aprindine are not less than 3000 and not more than 2.0, respectively.
System repeatability: When the test is repeated 6 times with 10 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of aprindine is not more than 1.5%.

(4) Residual solvent—Being specified separately.

Loss on drying <2.41> Not more than 0.5% (1 g, in vacuum, 60°C, 4 hours).

Residue on ignition <2.44> Not more than 0.1% (1 g).

Assay Weigh accurately about 0.5 g of Aprindine Hydrochloride, previously dried, dissolve in 80 mL of acetic acid (100), and titrate with 0.1 mol/L perchloric acid VS (potentiometric titration). Perform a blank determination in the same manner, and make any necessary correction.

Each mL of 0.1 mol/L perchloric acid VS = 35.90 mg of C<sub>22</sub>H<sub>30</sub>N<sub>2</sub>HCl

Containers and storage Containers—Well-closed containers.
Storage—Light-resistant.

Aprindine Hydrochloride Capsules

Aprindine Hydrochloride Capsules contain not less than 95.0% and not more than 105.0% of the labeled amount of aprindine hydrochloride (C<sub>22</sub>H<sub>30</sub>N<sub>2</sub>HCl: 358.95).

Method of preparation Prepare as directed under Capsules, with Aprindine Hydrochloride.

Identification Determine the absorption spectrum of the sample solution obtained in the Assay as directed under Ultraviolet-visible Spectrophotometry, it exhibits maxima between 264 nm and 268 nm, and between 271 nm and 275 nm.

Uniformity of dosage units <6.02> Perform the test according to the following method: it meets the requirement of the Content uniformity test.

Take out the contents of 1 capsule of Aprindine Hydrochloride Capsules, add 30 mL of a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125), shake vigorously for 20 minutes, add a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125) to make exactly V mL so that each mL contains about 0.2 mg of aprindine hydrochloride (C<sub>22</sub>H<sub>30</sub>N<sub>2</sub>HCl), and filter. Discard the first 5 mL of the filtrate, and use the subsequent filtrate as the sample solution. Proceed as directed in the Assay.

Amount (mg) of aprindine hydrochloride (C<sub>22</sub>H<sub>30</sub>N<sub>2</sub>HCl) = M<sub>S</sub> × A<sub>S</sub>/A<sub>T</sub> × V/250

M<sub>S</sub>: Amount (mg) of aprindine hydrochloride for assay

Dissolution <6.10> When the test is performed at 50 revolutions per minute according to the Paddle method using the sinker, using 900 mL of water as the dissolution medium, the dissolution rate in 15 minutes of Aprindine Hydrochloride Capsules is not less than 80%.

Start the test with 1 capsule of Aprindine Hydrochloride Capsules, withdraw not less than 20 mL of the medium at the specified minute after starting the test, and filter through a membrane filter with a pore size not exceeding 0.45 μm. Discard the first 10 mL of the filtrate, pipet V mL of the subsequent filtrate, add water to make exactly V mL so that each mL contains about 11 μg of aprindine hydrochloride (C<sub>22</sub>H<sub>30</sub>N<sub>2</sub>HCl) according to the labeled amount, and use this solution as the sample solution. Separately, weigh accurately about 28 mg of aprindine hydrochloride for assay, previously dried in vacuum at 60°C for 4 hours, and dissolve in water to make exactly 100 mL. Pipet 2 mL of this solution, add water to make exactly 50 mL, and use this solution as the standard solution. Perform the test with exactly 20 μL each of the sample solution and standard solution as directed under Liquid Chromatography according to the following conditions, and determine the peak areas, A<sub>T</sub> and A<sub>S</sub>,
of aprindine in each solution.

Dissolution rate (%) with respect to the labeled amount of aprindine hydrochloride ($\text{C}_{22}\text{H}_{30}\text{N}_{2}\cdot\text{HCl}$)

$$M_S \times A_S / A_L \times V'/V \times 1/C \times 36$$

$M_S$: Amount (mg) of aprindine hydrochloride for assay

$C$: Labeled amount (mg) of aprindine hydrochloride ($\text{C}_{22}\text{H}_{30}\text{N}_{2}\cdot\text{HCl}$) in 1 capsule

Operating conditions—

Detector: An ultraviolet absorption photometer (wavelength: 254 nm).

Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 μm in particle diameter).

Column temperature: A constant temperature of about 40°C.

Mobile phase: Dissolve 3.40 g of potassium dihydrogen phosphate in 500 mL of water, and adjust the pH to 3.0 with hydrochloric acid. To 500 mL of this solution add 500 mL of acetonitrile.

Flow rate: Adjust the flow rate so that the retention time of aprindine is about 6 minutes.

System suitability—

System performance: When the procedure is run with 20 μL of the standard solution under the above operating conditions, the number of theoretical plates and the symmetry factor of the peak of aprindine are not less than 3000 and not more than 2.0, respectively.

System repeatability: When the test is repeated 6 times with 20 μL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of aprindine is not more than 1.5%.

Assay

Take out the contents of not less than 20 Aprindine Hydrochloride Capsules, weigh accurately a portion of the powder, equivalent to about 0.1 g of aprindine hydrochloride ($\text{C}_{22}\text{H}_{30}\text{N}_{2}\cdot\text{HCl}$), add 60 mL of a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125) to make exactly 100 mL. Pipet 10 mL of this solution, add a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125) to make exactly 50 mL, and filter, Discard the first 5 mL of the filtrate, and use the subsequent filtrate as the sample solution. Separately, weigh accurately about 50 mg of aprindine hydrochloride for assay, previously dried in vacuum at 60°C for 4 hours, and dissolve in a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125) to make exactly 50 mL. Pipet 10 mL of this solution, add a solution of hydrochloric acid in diluted ethanol (1 in 2) (1 in 125) to make exactly 50 mL, and use this solution as the standard solution. Determine the absorbances, $A_T$ and $A_S$, of the sample solution and standard solution at 265 nm as directed under Ultraviolet-visible Spectrophotometry <2.24>.

Amount (mg) of aprindine hydrochloride ($\text{C}_{22}\text{H}_{30}\text{N}_{2}\cdot\text{HCl}$)

$$M_S \times A_S / A_L \times 2$$

$M_S$: Amount (mg) of aprindine hydrochloride for assay

Containers and storage

Containers—Tight containers.

Storage—Light-resistant.

Arbekacin Sulfate

アルベカシン硫酸塩

C$_{22}$H$_{44}$N$_6$O$_{10}$·xH$_2$SO$_4$ (x = 2 - 2½)

3-Amino-3-deoxy-α-D-glucopyranosyl-(1→6)-[2,6-diamino-2,3,4,6-tetraoxo-α-D-erythro-hexopyranosyl-(1→4)]-1-N-[2(S)-4-amino-2-hydroxybutanoyl]-2-deoxy-D-streptamine sulfate [51025-85-5, Arbekacin]

Arbekacin Sulfate is the sulfate of a derivative of dibekacin. It contains not less than 670 μg (potency) and not more than 750 μg (potency) per mg, calculated on the dried basis. The potency of Arbekacin Sulfate is expressed as mass (potency) of arbekacin ($\text{C}_{22}\text{H}_{44}\text{N}_{6}\text{O}_{10}$: 552.62).

Description

Arbekacin Sulfate occurs as a white powder. It is very soluble in water, and practically insoluble in ethanol (99.5).

Identification

(1) Dissolve 10 mg each of Arbekacin Sulfate and Arbekacin Sulfate RS in 1 mL of water, and use these solutions as the sample solution and standard solution. Perform the test with these solutions as directed under Thin-layer Chromatography <2.07>. Spot 2 μL each of the sample solution and standard solution on a plate of silica gel for thin-layer chromatography. Develop the plate with a mixture of ammonia solution (28), methanol, chloroform and ethanol (95) (7:6:4:1) to a distance of about 10 cm, and air-dry the plate. Spray evenly 0.2% ninhydrin-water saturated 1-butanol TS on the plate, and heat at 100°C for 10 minutes: the principal spot obtained from the sample solution and the spot from the standard solution are purple-brown in color and their $R_f$ values are the same.

(2) A solution of Arbekacin Sulfate (1 in 50) responds to the Qualitative Tests <1.099> (1) for sulfate.

Optical rotation <2.49> $[\alpha]_D^2$: +69 - 79° (0.25 g after drying, water, 25 mL, 100 mm).

pH <2.54> The pH of a solution obtained by dissolving 0.75 g of Arbekacin Sulfate in 10 mL of water is between 6.0 and 8.0.

Purity

(1) Clarity and color of solution—A solution obtained by dissolving 1.0 g of Arbekacin Sulfate in 5 mL of water is clear and colorless.
(2) Heavy metals <0.07—Proceed with 2.0 g of Arbekacin Sulfate according to Method 1, and perform the test. Prepare the control solution with 2.0 mL of Standard Lead Solution (not more than 10 ppm).

(3) Arbekacin—Weigh accurately about 20 mg of Arbekacin Sulfate, add exactly 10 mL of the internal standard solution to dissolve, add water to make 20 mL, and use this solution as the sample solution. Separately, weigh accurately an amount of Arbekacin Sulfate RS, equivalent to about 10 mg (potency), and dissolve in water to make exactly 50 mL. Pipet 5 mL of this solution, add exactly 10 mL of the internal standard solution and water to make 20 mL, and use this solution as the standard solution. Perform the test with 5 µL each of the sample solution and standard solution as directed under Liquid Chromatography 2.01 according to the following conditions, and calculate the ratios, Q₁ and Q₂, of the peak area of arbekacin to that of the internal standard. Calculate the amount of arbekacin by the following equation: not more than 2.0%.

\[
\text{Amount (mg) of arbekacin} = \frac{M_s}{M_f} \times \frac{Q_1}{Q_2} \times 1/10 \times 100
\]

\(M_s\): Amount (mg (potency)) of Arbekacin Sulfate RS
\(M_f\): Amount (mg) of the sample

Internal standard solution—A solution of becanamycin sulfate (1 in 2000).

Operating conditions—
Column: A stainless steel column 4.6 mm in inside diameter and 15 cm in length, packed with octadecylsilanized silica gel for liquid chromatography (5 µm in particle diameter).
Column temperature: A constant temperature of about 40°C.
Reaction coil: A column about 0.3 mm in inside diameter and about 3 m in length.
Reaction coil temperature: A constant temperature of about 30°C.
Mobile phase: Dissolve 8.70 g of sodium 1-pentane sulfonate and 8.52 g of anhydrous sodium sulfate in 980 mL of water, adjust the pH to 4.0 with acetic acid (100), and add water to make 1000 mL. To 230 mL of this solution add 20 mL of methanol.
Reagent: Dissolve 12.36 g of boric acid in 960 mL of water, add 10 mL of a solution of o-phthalaldehyde in ethanol (99.5) (1 in 25), adjust the pH to 10.5 with 8 mol/L potassium hydroxide TS, and add water to make 1000 mL. To this solution add 1 mL of 2-mercaptoethanol.
Reaction temperature: A constant temperature of about 50°C.
Flow rate of the mobile phase: 0.5 mL per minute.
Flow rate of the reagent: 1 mL per minute.

System suitability—
System performance: Dissolve 20 mg each of Arbekacin Sulfate, becanamycin sulfate and dibekacin sulfate in 200 mL of water. When the procedure is run with 5 µL of this solution under the above operating conditions, becanamycin, arbekacin and dibekacin are eluted in this order, and the resolution between the peaks, becanamycin and arbekacin is not less than 5 and arbekacin and dibekacin is not less than 1.5, respectively.

System repeatability: When the test is repeated 6 times with 5 µL of the standard solution under the above operating conditions, the relative standard deviation of the ratio of the peak area of dibekacin to that of the internal standard is not more than 2.0%.

(4) Related substances—Dissolve 20 mg of Arbekacin Sulfate in 200 mL of water, and use this solution as the sample solution. Pipet 3 mL of the sample solution, add water to make exactly 250 mL, and use this solution as the standard solution. Perform the test with exactly 5 µL each of the sample solution and standard solution as directed under Liquid Chromatography 2.01 according to the following conditions, and determine the area of each peak by the automatic integration method: the total area of the peaks other than arbekacin and dibekacin obtained from the sample solution is not larger than the peak area of arbekacin from the standard solution.

Operating conditions—
Detector, column, column temperature, reaction coil, reaction coil temperature, mobile phase, reagent, reaction temperature, flow rate of mobile phase, and flow rate of reagent: Proceed as directed in the operating conditions in the Purity (3).

Time span of measurement: About 1.5 times as long as the retention time of arbekacin.

System suitability—
System performance: Dissolve 10 mg each of Arbekacin Sulfate and dibekacin sulfate in 200 mL of water. When the procedure is run with 5 µL of this solution under the above operating conditions, arbekacin and dibekacin are eluted in this order with the resolution between these peaks being not less than 1.5.

System repeatability: When the test is repeated 6 times with 5 µL of the standard solution under the above operating conditions, the relative standard deviation of the peak area of arbekacin is not more than 5.0%.

Loss on drying 2.41—Not more than 5.0% (0.5 g, reduced pressure not exceeding 0.67 kPa, 60°C, 3 hours).
